Abstract: This study analyzes the implementation of Net.Create, a collaborative network analysis tool (Craig & Danish, 2018), in the context of a digital humanities classroom. Undergraduate students used network analysis to investigate historical objects gathered from the local community in a History Harvest. This paper focuses on the collaborative engagement of groups as they co-constructed conceptual frameworks in Net.Create to explain the individual, social, and cultural histories attached to these objects. Findings suggest that positive social engagement and metacognitive behaviors can support students' sustained engagement with historical and network analysis ideas. Interwoven personal-oriented and class-oriented social engagement in the data suggest that these forms of engagement can productively sustain engagement with cognitively demanding activities. Having built a supportive environment for collaboration amongst themselves, students were able to smoothly and effectively build on each other's ideas to generate an understanding of historical and network analysis patterns.

Keywords: student engagement, history, network analysis, CSCL

Introduction

Promoting student engagement with history has been an important goal for history learning research (Brush & Saye, 2008; Sakr, Jewitt, & Price, 2016). However, studies of student engagement in history often focus on a single variable, such as excitement (e.g., Squire & Barab, 2004) or empathy (e.g., Endacott & Brooks, 2013; Savenije & de Brujin, 2017). This contrasts with research in other disciplines, which often investigate the impact of multiple, interrelated dimensions of engagement on learning (Sinatra et al., 2015; Fredricks, 2011; Sinha et al., 2015). This paper explores a multidimensional framework of student engagement to understand mechanisms by which collaborative activity and network analysis can support deeper engagement with history learning. We analyze Net.Create, a collaborative network analysis tool (Craig & Danish, 2018; Craig et al., 2020), in the context of an undergraduate digital humanities classroom, where students were tasked with representing complex historical data for public consumption. Students used digital humanities tools (network analysis, mapping, and text analysis) to represent data gathered from a History Harvest. The History Harvest model brings students, academic researchers, and communities into partnership to preserve objects that tell personal and familial histories while keeping those objects with their owners. To accomplish this, history students photograph objects and conduct interviews about their importance for the community's history. Students then use digital tools to create interactive representations to display connections between personal, familial, cultural, and local histories.

This paper focuses on the collaborative engagement of groups that chose Net.Create to represent their objects. Net.Create engages students in detailed investigations of historical sources by providing a framework to support the contextualization of individual historical details in a complex web of people, places, concepts, and events. A persistent problem with history engagement is moving students beyond surface-level interest in a historical problem and towards the analysis and interpretation of historical sources (Brush & Saye, 2008). To understand how Net.Create supports this deeper engagement with historical analysis, we explore the following research question: *How did students engage behaviorally, cognitively, socially, and emotionally with and around Net.Create as they created networks of historical objects, and how did this influence their learning?*

Literature review

The History Harvest as a component of authentic historical thinking

Representing historical objects and their stories for the public offers unique opportunities for undergraduate engagement with history. Traditional large-lecture classes typically present history as a collection of facts to be memorized, thus obscuring how history is built up through multiple narratives and perspectives (Wineburg, 1991; Nokes, 2013; Wineburg, 2018). Engaging students in the authentic practices of historians—collecting artifacts, analyzing multiple narratives, and drawing connections—helps students refine historical thinking and argumentation skills that are key to the discipline (Shopkow, 2017; Martin & Monte-Sano, 2008; Lévesque, 2008).

In this study, some artifacts collected by students were passed down through generations, while others were found, purchased, or received as a gift. For instance, one contributor shared a Japanese kimono that her grandfather brought back from Japan after serving in World War II. Situating class activities in community history increases the likelihood of deep cognitive engagement, because students must generate a workable solution to a real-world question of historical practice without a predetermined "correct" answer (Hmelo-Silver, 2004). Such ill-structured problems ground learning in disciplinary knowledge and practices (Bae et al., 2019). Authentic problems can also engage learners' prior knowledge and experiences and motivate extended engagement (Hmelo-Silver, 2004; Blumenfeld et al., 1991). In this study, students were asked to represent historical objects in a way that reveals the social and cultural connections between them while also highlighting their unique features. This approach offers students authority over how they build historical arguments from a complex dataset and problematizes the notion of history as having one "true" perspective, both of which can influence learners' engagement with history learning (Freedman, 2020). To support students in navigating this open-ended problem, the Net.Create tool (see Design section) was offered to students as one option to explore, analyze, and represent this complexity.

Using the structure of network analysis to frame an ill-structured problem

Digital historians balance between different methodological approaches to the study of change and continuity as they negotiate structured network analysis and individual close-reading of primary sources (Gould, 2003; Padgett and Ansell, 1993; Graham, Milligan, Weingart 2016). The open-ended nature of that negotiation provides an ill-structured, authentic historical-thinking problem that encourages deep collaborative discussion. Making history palatable for the public is also an ill-structured problem because historical complexity can be represented in many forms. Students were tasked with using digital tools to answer team-generated research questions, such as "How do the cultural differences of each object affect how they serve as a mode of individual self-expression?" After entering data about their objects to explore possible answers, students created public web pages to communicate their discoveries. Groups then used Net.Create and network analysis methods to investigate the multiple historical narratives attached to their objects and generate a representation to help the public interpret these histories.

For network analysts, decisions about transforming the open prose of historical primary sources into structured data shape which elements of the dataset are highlighted or obscured (Durland & Fredricks, 2005). Networks are composed of nodes (circles which represent people, places, objects, and concepts) and edges (lines connecting the circles which represent relationships between nodes). Students make decisions about types of nodes to add to the network as well as types of relationships between nodes that are worth highlighting. These decisions affect how viewers interpret the final network, because well-connected nodes will appear larger, signifying the importance of that object or concept for the overall network. The types and numbers of edges created will also influence which nodes have high measures of betweenness, or in other words which nodes link parts of the network that would be otherwise unrelated (Carrington, 2005).

Student engagement in building a collaborative network of history

Students are more likely to engage deeply with learning in a task that is authentic for both disciplinary practice and complexity (Calabrese Barton & Tan, 2010). To capture this engagement, it is useful to conceptualize engagement as containing multiple, overlapping dimensions (Fredricks, Blumenfeld, & Paris, 2004; Fredricks, 2011). Behavioral, cognitive, and emotional dimensions are commonly agreed upon as key aspects of engagement (Fredricks et al., 2004). Social engagement has also been recognized as a fourth significant dimension, given the importance of mutually respectful interactions for collaborative learning (Sinha et al., 2015; Isohätälä et al., 2018). This multidimensional conceptualization highlights that engagement is not a static attribute, but rather a dynamic state that unfolds over time and is transformed by context (Fredricks, 2011; Sakr et al., 2016). It is important to note that studying a single facet of engagement is not only theoretically problematic, but it does not reveal the complex mechanisms by which behavior, cognition, emotion, and social relationships interact to open or foreclose opportunities for learning more broadly (Sinatra et al., 2015). The present study takes a multifaceted approach to understand how emotional connections shape and are shaped by social engagement and in turn deepen students' cognitive engagement with historical and network analysis concepts. Drawing on frameworks that have been applied in other disciplinary contexts (Fredricks et al., 2004; Sinha et al., 2015), we conceptualize engagement along behavioral, cognitive, social, and emotional dimensions to capture the complex ways that engagement unfolds over time as learners interact with each other and their environments (Sinatra et al., 2015).

An analysis of engagement in context requires the application of a sociocultural theoretical lens, which views engagement as a dialectic give-and-take process between learners and their social, cultural, and political environments (Sinatra et al., 2015). Engagement cannot be separated from the contexts in which it is produced—in other words, it cannot be captured in a single decontextualized snapshot but must instead be understood as "unfolding in place and time" (Sakr et al., 2016, p. 84). From this situated perspective, surveys of individual engagement variables are not enough, and analyses should instead take up a frame of learners-in-context that highlights social positioning, available forms of participation, and the collective meaning assigned to these interactions (Nolen, Horn, & Ward, 2015). Behavioral, cognitive, social, and emotional dimensions are interwoven together in interactions between learners, so it is not always easy to operationalize where one dimension ends and another begins (Fredricks et al., 2004). To clarify dimensional boundaries, we consider behavioral engagement as the overarching visible "evidence" of learners' engagement (e.g., entering network data into the computer), and cognitive, social, and emotional engagement as different goals that engaged behaviors may fulfill. Behavioral engagement encompasses ways in which students participate in the activity that surrounds them (e.g., asking questions, taking notes; Fredricks et al., 2004). The other three dimensions can then be defined through subsets of behaviors that make conceptual ideas, social relationships, and emotional reactions visible to other participants. Engaging along one dimension is good (e.g., taking notes), while engaging along multiple dimensions is better (e.g., taking notes while expressing excitement and soliciting contributions from peers).

Cognitive engagement is defined both as learners' reflections on conceptual ideas, questions, and problems (Sinha et al., 2015) and as their use of metacognitive strategies to control and improve their learning (Greene, 2015). This dimension can be analyzed through the public negotiations and discussions that students engage in as they work to represent their historical data together. Collaborative activities are a powerful way to foster cognitive engagement because students must explain and justify their ideas to their peers (Gresalfi, 2009). In the context of Net.Create activities, students must determine what conceptual links to create between objects, such as geographic origins, cultural traditions, and personal experiences. They also negotiate network structures (e.g., what counts as a node or an edge) so that conceptual links are visible and interpretable to network viewers.

Collaboration can also socially engage students when groups thoughtfully consider and respect the contributions of all members (Sinha et al., 2015). Positive social engagement reflects "learners' abilities and efforts to sustain cohesive, mutually respectful social interaction...including developing trust and fostering safety for collaboration and building a sense of community with a shared goal" (Isohätälä et al., 2018, p. 2). This might look like a balanced discussion in which each student can share and safely debate ideas without risking rejection. Negative social engagement would be seen through exclusion, ignoring the perspectives of group members, or social loafing (e.g., letting one person do all the data entry while others text on their phones) (Isohätälä et al., 2018). The instructor encouraged positive social engagement in this study by having each student take responsibility for a different set of historical objects, which they then had to add to their group's network.

The network tasks supported by Net.Create offer students a way to engage emotionally as well, which can be defined as the positive and negative reactions that learners have to activities (Fredricks et al., 2004). Students' emotional engagement with history can influence the extent to which they identify with people from the past, as well as their creation of links between past and present experiences (Sakr et al., 2016). Thus, supporting students in experiencing emotional reactions such as curiosity and empathy is central to the design of engaging history learning activities. When creating connections in Net.Create, students were encouraged to consider the perspectives of the people, families, and cultures who the objects belong to, which could help them identify and empathize with the emotional links that these people had to their donated objects (Endacott & Brooks, 2013).

Design

The Net.Create software (Craig & Danish, 2018) is designed to support collaborative, simultaneous data entry into a live network visualization, so that groups can enter and revise data to represent relationships between individual people, objects, and ideas in a complex dataset. To generate a visualization, students added nodes (objects, places, people, events, and concepts) into the network and then linked these nodes using edges (categories of relationships that describe how two nodes are connected) (Figure 1). Each node and edge entry had text boxes for students to explain historical significance and how the entry relates to the overall network. Nodes with many connections grew larger and pulled smaller nodes towards them to represent their growing importance.

Analyzing relationships between central nodes and outlier nodes helped students identify connections between gathered objects and was one of three digital methods students could choose after they completed the history-harvest portion of the course (see "authentic historical thinking" above in lit review). To support students as they transitioned from the community-interaction unit to the analysis unit, several mid-semester class sessions were set aside for in-person data entry and analysis. The sessions are labeled Days 1-4 to denote their chronological sequence but were not consecutive—the research team gathered data from a sampling of class periods across the semester to capture group engagement as it shifted over time. On Day 1, students drafted research questions to guide their analysis of objects collected from the History Harvest. On Day 2, groups entered data about their objects into Net.Create and analyzed connections between their objects' histories. On Day 3, they used evidence from their networks to draft paragraphs for web pages, to explain to the public their discovered patterns. Finally, on Day 4, they gave final class presentations summarizing their group's historical research.

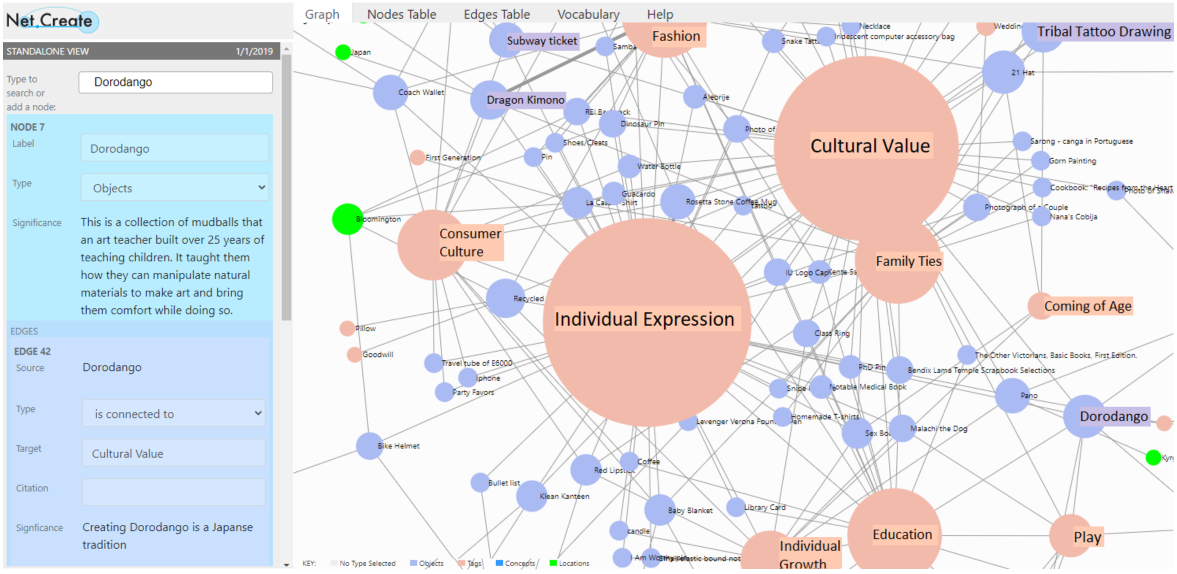

Figure 1. A node and edge entered by students (left) in their network of historical objects and concepts (right)

Methods

This paper focuses on the collaborative engagement of one focus group (n = 3 students) in a 25-student undergraduate digital history course at a large university in the Midwestern United States. A qualitative analysis of this group's interactions allowed us to explore how cognitive, social, emotional, and behavioral engagement intertwine to support students' learning during group work. The dataset, which consists of 4.5 hours of group audio data drawn from four different class sessions, was segmented into 30-second segments to give coders a standard unit of analysis for tracking engagement patterns (Isohätälä et al., 2018). We established seven general codes from the literature: 1) Metacognitive behaviors; 2) Positive emotional reactions; 3) Negative emotional reactions; 4) Positive social interaction; 5) Negative social interaction; two cognitive-conceptual codes capturing discussions of 6) Historical argumentation and 7) Network analysis concepts. The codes were used to tag engagement patterns and identify key episodes rather than evaluate discussion quality. Coders applied each code only once per 30-second segment and applied as many codes as were applicable for that segment. A second coder analyzed 1 hour of data to provide interrater reliability measures (1 / 4.5 hours of data, or 22% of the dataset).

Because behavioral engagement takes a variety of forms (e.g., active listening, independent work) and provides evidence of the other three dimensions, we did not code for behavioral engagement but instead analyzed it qualitatively in selected episodes. We identified episodes in which multiple coded dimensions of engagement overlapped to explore the complex interactions between dimensions, which are not yet well understood (Sinatra et al., 2015). For example, episodes of extended social engagement mixed with metacognitive and conceptual engagement were pulled to explore how these dimensions might be building on one another to support learning. These episodes of complex engagement were then qualitatively analyzed using interaction analysis (Jordan & Henderson, 1995), which involved multiple rounds of listening to audio clips, transcription of key episodes, and analysis of screen capture and video data when available to contextualize student conversations.

Findings

Coding of group interactions revealed that positive social engagement and metacognitive behaviors were most common. For example, Figure 2 shows group engagement across Day 1, with minutes 0-24 of class on the first line, 25-49 on the second line, and 50-72 on line three. Each column represents one 30-second segment of activity. Group members were periodically monitoring their collective progress, voicing confusion, asking for help, and clarifying goals and plans (i.e., cognitive engagement via metacognitive behaviors). They also consistently solicited ideas, responded to contributions, affirmed the value of peers' ideas, and engaged in friendly teasing and humor (i.e., social engagement via positive group interactions). The other five general codes also appeared across the dataset, though less consistently. Negative emotional and negative social engagement were relatively rare (e.g., negative social engagement did not appear on Day 1), while positive emotional engagement was moderately common but not as consistently present as positive social engagement. Most positive-emotion moments appeared as laughter around teasing or humor. Finally, historical argumentation and network analysis discussions were also moderately present, often towards the end of class during group review of network entries and webpage writings.

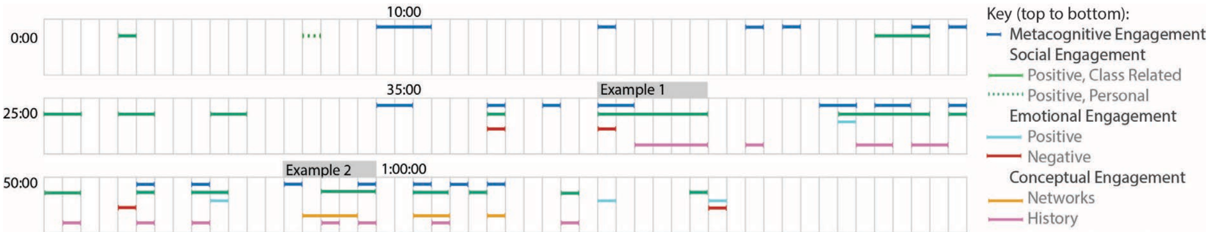

Figure 2. A timeline of the focus group's engagement along the seven coded dimensions during Day 1

Given the consistent presence of positive social engagement and metacognitive behaviors, we focused our qualitative analysis on the possible functions of these forms of engagement in supporting students' conceptual understanding. We present two episodes below demonstrating how these dimensions overlapped in discussions. In the first example (Table 1; Example 1 in Figure 2), our focus group (Patrick, Aubrey, and Jordan) have joined with another group (Students 1-3) to brainstorm research questions. The segment begins with several metacognitive behaviors: Patrick agrees to take notes, and Aubrey reminds him that the goal is to record their brainstorming. Aubrey and Jordan then organize the discussion by proposing that everyone share what object they have been studying. When Student 3 says his object too quietly, the group responds with positive social engagement in the form of polite questioning, re-voicing, and a bit of humor that carries on for ten lines of talk (one student misheard and thought Student 3's object, a subway ticket, was a Subway cookie from the sandwich shop). The discussion preceding the transcribed segment intertwines cognitive and social engagement as students use metacognitive behaviors to steer the conversation towards a collective goal. Students are consistently socially engaged, using laughter and humor to keep the conversation moving when a student is briefly misheard. This social engagement then transitions seamlessly into a discussion of potential concepts to organize their analysis:

Table 1: Positive social engagement in the form of respectful disagreement

Line	Speaker	
1	Aubrey	I feel like individual expression is probably
2	Patrick	Individual expression is definitely—like I think everyone can hit on that
3	Aubrey	Mhmm
4	Jordan	That's uh
5	Patrick	Cause they're all individual items
6	Jordan	Individual expression um…like it could get even deeper into cultural expression too
7	Patrick	I was gonna say even sediment—sen-i-ment—like, how sentimental it is
8	Aubrey	Mine's not very sentimental
9	Patrick	Oh, no?
10	Student 2	Same here
11	Patrick	Oh really?
12	Aubrey	Mine are just—
13	Student 2	Just tattoos
14	Jordan	Mine's pretty sentimental
15	Student 2	It's not sentimental, it's just more of a—like the self-expression angle
16	Jordan	See mine's more of like a sentimental tattoo
17	Student 2	What?
18	Jordan	It's like a more of like a tribal tattoo from like a ((inaudible))
19	Aubrey	Mine is—mine is used in education. To play as development...so
20		((inaudible side conversation))
21	Aubrey	I don't know if that technically- if that would fit with sentimentality. I feel like that's more of like- Like, how I- how I'm relating it to individual expression is through individual growth rather than sentimentality

In this discussion, students shift fluidly between multiple forms of engagement as they share ideas and negotiate what aspects of their historical objects should shape group analysis. Positive social engagement transitions seamlessly into a historical analysis of potential categories to address similarities between the group's objects (lines 1-7). When Aubrey and Student 2 respectfully disagree with a suggested category, Patrick pauses to question and listen to their reasoning for not wanting to use sentimentality as a conceptual frame (lines 8-11). These respectful interactions influence how the group's final network (Figure 1) unfolds—the group leaves out sentimentality and instead uses family ties, cultural value, coming of age, individual expression, and individual growth to better represent the similarities and differences between their objects' histories. This positive group functioning, with its blend of supportive, light-hearted discussion and guiding metacognitive behaviors, appears frequently in our focus group's interactions. While some might assume social engagement would distract from disciplinary engagement, it appeared in many cases to advance engagement with conceptual ideas. In a later episode (Table 2; Example 2 in Figure 2), our group again engages in metacognitive behaviors by reflecting on their research questions and assessing how their collaborative network sheds light on their data.

Table 2: Positive social engagement in the form of building on one another's conceptual ideas

Line	Speaker	
1	Aubrey	I feel like our question actually—I feel like our question actually like works well
2	Patrick	Mhmm
3	Aubrey	With (.) um network analysis, because like the middle of the structure is like, individual self-expression then, our branches are like—you know how I was saying earlier like individual growth as ((inaudible)) education, individual growth as a mode for self-expression. So then my like, thing related to it is like, individual growth. And then through that I would have like all the things relating to mine. And then you guys would have the same
4	Both J&P	Yeah
5	Aubrey	And there are probably crossovers between
6	Jordan	Yeah, and like with individual growth on yours, mine's about coming of age
7	Aubrey	Yeah
8		[…] ((group briefly clarifies which research question they're talking about))
9	Patrick	Cause each of us has a different object, and like not saying that tattoos are similar, but they're not—they have totally different meanings
10	Aubrey	Right. Right right. Right.
11	Patrick	So yeah you're totally right, as long as we have a center-
12	Aubrey	Like and I think the center-
13	Patrick	-we each branch out and we'll find like smaller parts that each go together
14	Aubrey	And like I feel like our center can literally just be individual self-expression, like as simple as that
15	Patrick	Yeah, that's what I was thinking
16	Aubrey	And then I feel like our network analysis, you know how she ((instructor)) was saying like, there's something that always ends up, like in the- it gets like super centralized
17	Patrick	Yeah. They'll be different parts that come together, and we'll find that out soon as they come out

This episode demonstrates a solid collaborative foundation that supports conceptual richness. Students negotiate their collective understanding and affirm the value of peers' ideas. Throughout the segment, all three group members offer small verbal acknowledgements (e.g., "mhmm", "yeah", "totally") to encourage one another's continued sharing of ideas. Aubrey makes important observations about how branching nodes and centralized nodes highlight relevant conceptual tags, and Jordan responds to Aubrey's mention of "crossovers" by noting a commonality between his object and Aubrey's (line 6). Patrick also builds on Aubrey's ideas with multiple explicit affirmations ("you're totally right", line 11) while adding his own idea that building the network will reveal emergent patterns (line 17). The group's final network (Figure 1) reveals how these early negotiations supported later engagement with the Net.Create tool. Jordan and Aubrey's objects do indeed end up in "branches", with Aubrey's dorodango linked to education, play, and individual growth, and Jordan's tribal drawing tattoo linked to coming of age and cultural value. Patrick's comment about ideas coming together (line 17) also played out in the group's network. The group predicted individual expression would be an important concept (line 14), but cultural value also became a central node. This engagement with network analysis structures helped this group engage with the history as well. Linking their objects to distinct conceptual tags helped make visible Patrick's understanding that a tattoo isn't just a tattoo (line 9)—each object has its own history and sources of meaning.

After the transcribed segment, the discussion wraps up with another blend of social support and humor. Patrick's "Good job, Aubrey" was met with thanks and Aubrey's joke that "there's a brain in here sometimes." These small moments of positive social engagement, which may seem insignificant in isolation, appear to build up across the activities, providing a consistent supportive context in which to negotiate evolving ideas. Based on the glimpse this focus group provides into the benefits of social engagement and metacognitive behaviors, positive social engagement has the potential to form a foundation for future engagement, with teasing and humor not only creating a positive context for discussion but also sustaining engagement through moments of confusion or frustration. For example, in other focus episodes students joked about having no idea what's going on as a light-hearted bid to solicit support from group members without directly asking for help. Productive behavioral and conceptual engagement (e.g., entering data into the network) also often coincided with personal-oriented positive social engagement (e.g., discussing plans for the weekend), which typically lasted for only a minute or two before the group returned to discussing the task. This suggests that class-oriented and personal-oriented engagement could sustain one another productively and provide temporary breaks during a cognitively demanding activity. It is likely that such complex relationships between forms of engagement could perform a variety of functions depending on context, and so future research should investigate additional patterns in how these dimensions interact with one another.

Discussion and conclusions

The complex potential interactions between social engagement, metacognitive behaviors, and other aspects of engagement suggest that engaging students deeply with history learning requires a consideration of how activities are structured to support positive group interactions. The extent to which collaborative group members support one another's ideas and encourage sustained participation in the face of obstacles may have a significant influence on their synthesis of historical ideas. Additionally, a classroom environment that encourages voicing confusion and seeking help can support students in monitoring their own understanding and the collective understanding of peers. Much of the conceptual work that students were engaging with was not visible in discussions with their group members; instead, it was more apparent in their writing. Net.Create offered students an alternate pathway for making their cognitive engagement with history visible to each other through prompts to write about the significance of each object. Students could move from entering individual historical details into the network to making higher-level summaries of patterns in their group discussions, constructing both individual understandings of their objects and collective understandings of how these objects are conceptually related. The combination of positive social and cognitive engagement appeared to help groups sustain their engagement across long periods of independent group work, with group members periodically checking in with one another and bolstering group cohesion with light-hearted jokes. While such aspects of positive social engagement may appear tangential to learning at first glance, qualitative analysis of this focus group suggests that small moments of humor, supportiveness, and mutual respect can set the stage for later moments of deep conceptual engagement. This highlights that cohesive group functioning, which plays a central role in collaborative science learning contexts (Sinha et al., 2015; Isohätälä et al., 2018), may be of central importance for history learning, as well. Having built a supportive environment for collaboration, these students effectively constructed a collective understanding of historical and network analysis patterns and made those patterns visible for their community.

Abstract: Experience is an important dimension of learning (Roth & Jornet, 2014). Research has drawn attention to the importance of equitable learning environments where all students experience opportunities to contribute to knowledge-building activities. Working in partnership with five middle school science teachers and two instructional coaches, we have developed a visual learning analytics system that aims to support teachers in reflecting on variability in students' classroom experiences linked to race and gender. This system, the Student Electronic Exit Ticket (SEET), captures and visualizes student experience data related to three constructs that prior research indicates are reflective of equitable classroom experiences: coherence, relevance, and contribution. We share findings from a qualitative study of how the SEET system visualizations supported teachers and coaches to recognize and respond to classroom inequities. Further, we discuss our design process with teachers and how this partnership influenced the visual feedback display.

Introduction

It is critical to make science meaningful to students from a wide variety of backgrounds, identities, languages, and cultures. Equitable practices in science classrooms are supported when we are able to make science culturally relevant to all students. Students can have inequitable learning experiences when teaching and subsequent actions are idealized in potential harmful ways based on learner attributes, such as geography, zip code, language, religion, gender, race, ethnicity, or socio-economic status (Brown, 2019). For instance, a student's way of speaking or their choice of clothes can deem them as not intelligent to the teacher, and these perspectives on ability can be rooted in biases around culture and race. This has been called the "Black Tax" in science classrooms, which refers to the "additional hurdle or cost faced by many students of color" (Brown). This black tax narrative is not only restricted to Black communities, instead it frames the narrative of many non-white populations who experience challenges (Brown, p.13).

In order to disrupt this narrative and create equitable learning environments, teachers need ways to more deeply recognize, understand, and engage with their students' experiences of the classroom. Attending to students' experiences involves integrating the practical, intellectual, and affective dimensions of classroom life (Roth & Jornet, 2014). Understanding students' experience in the classroom can help science teachers alter their instruction in ways that make it more culturally sustainable for a diverse student body, across gender and race (Paris & Alim, 2017). Penuel and Shepard (2016) note that helping teachers to understand the socio-cognitive dimensions of classroom experience (attending to the social nature of cognition) and the socio-cultural dimensions (attending to the value of participation in disciplinary ways of knowing and doing) of their students' experiences can support efforts to promote equity in classrooms.

Taking a student-centered approach and gathering reliable information about students' experiences in the classroom sheds light on the learning community and processes from students' perspective (Penuel & Watkins, 2019). Drawing on recent efforts to produce 'Equity Analytics' as a quantitative approach to view patterns of equity and inequity in classroom participation across gender and race (Reinholz & Shah, 2018), we have developed an innovative system of surveys and visualizations that captures and visualizes student experience data revolving around three constructs: coherence, relevance, and contribution. The Student Electronic Exit Ticket (SEET) system includes three major components: multiple versions of a student survey that can be administered anonymously in classrooms, a data management component, and a corresponding analytical system for teachers that visualizes these survey responses and disaggregates them by gender and race. In this study, we examine how different visualizations of student experience data during design process of the tool can support teachers to understand and reflect on the experiences of diverse students in their classrooms. We also report on how adopting a user-centered design process helped in selecting and adapting the user interface of the SEET system.

In our research, we worked closely with five middle school science teachers and two instructional coaches to design the visualizations and understand affordances offered by different representations for identifying patterns of equity and inequity of experience in science classrooms. Our ultimate goal is to develop analytic and instructional routines that help teachers to interpret these data and use them to reflect on their classroom instruction. The following research questions guided this paper: 1. How do different data visualizations create different opportunities for teacher's sense-making? 2. In what ways does visualizing students' experience data promote teachers' reflections on equitably supporting students' needs?

Conceptual framework

We argue that supporting equity involves understanding learners' experiences based on three constructs: coherence, relevance, and contribution (Reiser et al., 2017, NASEM, 2018, Miller et al., 2018). To this end, we have created an experience based formative assessment premised on these constructs called the Student Electronic Exit (SEET). SEET data provide targeted information about learners' experiences within a particular academic unit and classroom. Each construct comprises a unique set of questions. SEET questions related to coherence ask students whether they understand how current classroom activities contribute to the purpose of the larger investigations in which they are engaged. Coherent learning experiences appear connected from the students' perspective, where the progression of learning experiences is driven by student questions, ideas, and investigations (Reiser et al., 2017). Questions related to relevance ask students to consider the degree to which lessons matter to the students themselves, to the class, and to the larger community (Penuel et al., 2018; NASEM, 2018). For contribution, SEET questions ask students whether they shared their ideas in a group discussion, heard ideas shared by others, and whether others' ideas impacted their thinking. The aim of using the SEET assessment in the classroom is not to judge teachers or identify students' understanding of disciplinary content. Rather, the SEET assessment is intended to help create an environment for improving teacher instruction and diminishing classroom inequity.

Overview of the SEET system

The SEET system uses experience sampling to gather information about students' classroom experiences. Experience sampling is a technique for gathering data about how people feel and think during random intervals in their lives (Larson & Csikszentmihalyi, 2014). In our context, the teacher decides when to sample students' classroom experiences. The SEET system uses a thirteen-item survey to gather information from students on their perceptions of coherence, relevance, and contribution for that day's classroom experiences. This survey is designed to take only a few minutes for students to complete at the end of a class session. It is important to note that the SEET system does not collect names of students, provide individual-level feedback to teachers, nor does it display disaggregated data across gender and race if there are fewer than three students belonging to a particular gender or race to protect the anonymity of the students. Key steps in the workflow for teachers and students are: (1) The teacher administers a survey that asks students to reflect on today's classroom experiences, (2) Each student in the class receives the survey and reports on their experience, (3) Student responses from the entire class are combined and displayed to the teacher through a visual analytics dashboard based on the three focal constructs, (4) Teachers reflect on the student experiences' with visualizations

Data and study methods

We recruited five middle school science educators (two identified as female and three as male) and two science instructional coaches (one female and one male) from a large, urban school district in the Midwest to participate. The materials for this study included 30 different visualizations across three constructs. Round one included visualizations from a made-up dataset created by the first author that had significant differences in student experience across gender and race. For round two, we drafted visualizations using actual classroom data collected from a middle school science teacher's classroom in the same school district. This teacher was not a study participant.

In Round One, three science teachers (one female and two male) and two science instructional coaches (male and female) were asked individually and in pairs to reflect on selected visualizations from a pool of 14 different visualizations. Each session took 30-35 minutes. Teachers were shown a visualization and asked to think aloud as they tried to interpret its meaning and its implications for teaching. Think aloud protocols are a technique for understanding the cognitive processes of the participant when a stimulus is introduced during decision making (Ericcson & Simon, 1993). After each think-aloud, teachers completed a short interview about each visualization. During the interviews, we probed teachers about their thinking, asking them "What are you wondering about, assuming this is a real classroom? What is the need in your classroom that this visualization points to, if this were your classroom's data?". After seeing all the visualizations, we asked teachers to tell us which ones they believed to be most useful for helping them monitor their students' classroom experiences.

For Round Two, the same investigative process was followed with two science teachers (one female, one male) and the number of visualizations was increased to 30 (the 14 from Round One and 16 additional visualizations). New visualizations were created to address teacher feedback from Round One.

To gain deeper insights into how specific visualizations supported teachers' reflection processes, we analyzed our qualitative data with an inductive lens using a grounded theory approach to identify themes (Charmaz, 2014). The first author went through all the transcripts line by line to develop a preliminary code book. This preliminary codebook was developed into a mutually exhaustive and exclusive code book as shown in Table 1, after two authors met multiple times to reach consensus. The high-level codes included "Data reflection", "Interpretability and Recommendations". Within each high-level code there are multiple sub-codes. The two coders established high levels of interrater agreement calculated using Cohen's Kappa; κ= 0.88 for Data Reflections and κ= 0.89 for Interpretability and Recommendations.

Table 1: Coding teachers' responses to the data visualizations

High level Codes	Sub-codes	Examples
Data Reflection	• None: Teacher finds nothing • Find: teacher finds a particular data pattern. • Inquire: Teachers reflect on student experience data possible relationships between constructs and findings. • Instructional need or aim: Teacher thinks on what can be the next steps. • Pointing towards equity: Teacher talks about students from non-dominant groups and BIPOC, and/or when teacher talks about "equity" or "inequity" across gender or race.	• Find: "If you answered questions last, did you share any ideas out loud today. That is really striking to me." • Inquire: "I am curious about these don't know categories, what commonalities are there between those statements?" • Instructional need or aim: "So, I would think that's like something on me to make sure I'm tying it back to like our bigger picture." • Pointing towards equity: "Did anyone else share? 85% say others shared? To me, this kind of points to a sense of inequity."
Interpret-ability and recomme-ndations	• None: Teacher doesn't interpret and provide recommendations • Hard Identification: Hard to interpret the visualization • Easy Identification: Easy to interpret the visualization • Attraction or compelling point: Teacher reasoning about the compelling and attractiveness in visualization • Anytime Principle: Teacher has some anytime principle in mind on how to read visualization. Sense-making process tied up with the anytime principle. (Russel, Stefik, Pirolli, &, Card, 1993) • Design Suggestion: Teacher provide design suggestion for interpretation of the visualization • Construct Suggestion: Teacher provide suggestion related to constructs of the survey item SEET	• Hard Identification: I'm wondering about if I think the volume bubbles are kind of a neat idea for an easy glance piece. But I'm also maybe struggling to find how helpful they are. • Easy Identification: "One of the things just like overall style, I like looking at the colors, color gradation a lot better." • Attraction or compelling point: "It's a lot better, a lot easier to figure out what's being visualized. Than the size" or "I like this, I think the most because it gives me data per population" • Anytime Principle: "But it took like, my eyes kept fluttering back and forth, and back and forth, and back and forth. And then I was just jotting. We've got tables, bar graphs, what do I need to look at first? So finally, I just started looking at this table." • Design Suggestion: "I would like them portioned out per population. so, you could quickly see the smallest population or the largest percentage" • Construct Suggestion: "Knowing my students, that's the comfort area. If I don't understand that question, or I don't know it, I'm gonna choose."

Results and discussion

During round I, the first three teachers selected visualizations: Horizontal Stacked Bar Chart, Line Chart, as these supported them in the sense-making of data. Both coaches selected: Choropleth Heat map, Bubble chart, and Line chart, provided the most appropriate sense-making to them. From round II with two science teachers they selected visualizations: Horizontal Bar Chart, Choropleth Heat map, Line Chart. We finalized the 'Horizontal bar chart with '%yes' only', 'Choropleth Heat map with disaggregation of gender and race' and 'line chart' into the visual feedback displays of SEET shown below created from a made-up dataset.

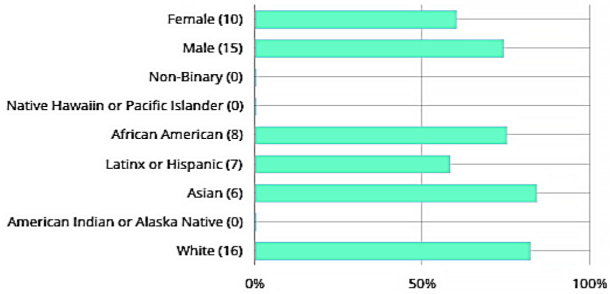

Figure 1: Bar Chart by Gender and Race

Figure 2: Choropleth Heatmap by Gender and Race

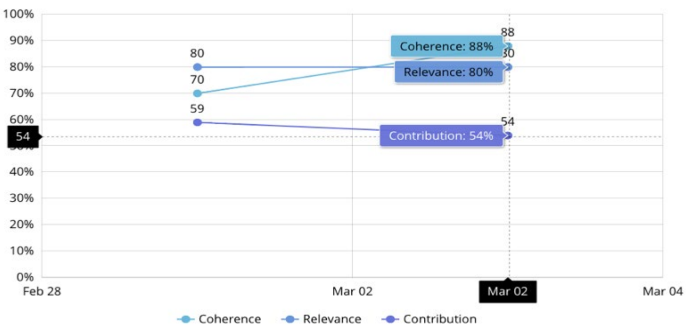

Figure 3: Over time by Coherence, Relevance, and Contribution

We found that the side-by-side bar charts facilitate easy comparisons, when they show a simple percentage of "yeses". We implemented small multiples of bar charts (figure 1), adjacent to each other as suggested in prior work by Heer, Bostock & Ogievetsky (2010). The choropleth heat map in figure 2 displays data disaggregated by gender and race, the first three rows at the top display different genders, and then there is intentional space to start with different race categories. These categories are based on the U.S. census. Each column at the top belongs to lesson or measures (coherence, relevance, and contribution) related questions. Color facilitates thinking about the dimensions of experience that are being measured. Although the color is less precise as compared to position based visual representations such as scatterplots, bar graphs, and line graphs, they provide a significant 'big picture' information to the users (Albers et al., 2014). The line chart in figure 3 is one type of implementation of its three variants: i) line chart visualized by correct average of SEET measures over time (see Figure 3) ii) line chart visualized by gender and race data over time for a single classroom period iii) line chart visualized by each question over time for a single classroom period. All these visualizations and variants are implemented in the SEET system.

Now we present data from teachers and instructional coaches for both rounds on how their interaction with different visualizations supported several reflections on equity and instruction prompted different reflections on student experience and how it helped in shaping the design of the user interface of the SEET system.

Data reflection

Analysis of our qualitative data suggests that these selected visualizations in figure 1, 2, 3 can be effective in supporting teachers to reflect on their students' classroom experiences. We now present a few cases where teachers expressed their perceptions related to student experience.

Mr. Alan (Science Teacher), all names are pseudonyms, when asked on what they see looking at data patterns in the horizontal disaggregated bar chart visualization (Figure 3), he responded:

> So, within the kind of the first boxes up here, there is a group of students who seem to be making more sense of the driving question and how it ties into less, and then other students. And it's looking like it's just the white students better following along better with the driving question board and how it ties into what they did in class and the unit, things like that. But then when we transition down to the other questions, matters to the people in the community and things like that. I'm not really seeing much there in terms of some overall takeaways, except for maybe the Black students. I don't know how many are in there, though. Like, is that 18%? That one kid or total of five? Okay, there? Yes, I see it now. Total five kids. Okay. So, one of those five kids found that it tied back to their community and things like that, but the four of the five basically didn't notice that. (Mr. Alan, round II)

Mr. Alan in his reflection on what is the instructional need based on this classroom, responded:

> The instructional need would probably be making this culturally relevant to all students in the classroom, making sure that all students do find a connection to it, whatever they're learning, because it's clear that all students aren't finding that connection from the lesson to what's important to them or their community, only some students are, and it's solely dependent on cultural background or ethnicity. (Mr. Alan, round II)

Mr. Alan showed concern about the Black students who didn't have the same percentage of "yeses" as the other students in the classroom. He tied the classroom experience to the classroom environment: saying it was not conducive to all the students from different backgrounds and cultures. In most parts of the interview Mr. Alan was concerned about the instructional connection to minoritized students such as Asian students and how to make it a more positive environment by making lessons coherent and equitable.

Similarly, when Mr. Meer and Mr. Tim (Science Teachers) are asked what they notice from the data visualization showing change over time, how they might use this data formatively for thinking or reflecting on things in classrooms, Meer responded:

> It's interesting that overall, we see it trending upwards. Like, obviously, I feel like that's each piece of the lesson building on itself, but super big drop off for lesson 3D for males and yeah, a big spike there for females so again, there had to be some kind of a gender disconnect when we get to lesson 3D. Yeah, lesson 3D obviously was off. So, it'd be a good starting point to look there. How can we make lesson 3D more equitable? I think it would definitely give me some empathy; especially like you said for here in coherence for females. (Meer, Round I)

While Mr. Meer pointing towards disaggregated bar chart question on coherence, he reflected:

> I would definitely drive my instruction to help to target this group, clearly. This was my classes with my data, I did not do my job enriching these female students. So, that would really cause me to go back and reflect and hopefully make some changes. This piece of data allows me to just directly ask them, what did you need that I didn't give you? (Mr. Meer, Round I)

Tim and Meer, both noticed the experience of the female students as not to the level of male students in the classroom. Meer was concerned about what he didn't do to make the classroom experience better for the female students and how he would inquire with students to make a better classroom connection across the parts of the unit to make an equitable environment for them. Mr. Tim and Mr. Meer both agreed that over time data can be helpful for them in identifying connections across the units and also disaggregated bar charts would help them target more specifically each classroom for coherence, relevance and contribution.

Mr. John and Ms. Becky (Instructional coaches), when asked about what's the instructional need based on the bubble chart representation, Mr. John pointed to inequity of experience related to the relevance for the students.

> Deeper piece and harder the relevance question six, there's an imbalance for who this seems to apply to. There's definitely a certain level of students who aren't feeling like this, this describes

> them. So that's like a larger piece. Like, which curriculum are we using? How do we want to make adaptations larger across our district. And then thinking about the training for those pieces. If we had the time to do professional learning. What implementations will we do? (Mr. John, Round I)

Mr. John's explanation pointed to the need for more relevant instruction for improving student experience on this construct. He indicated that few groups of students are not finding relevance with the lesson and how he can scaffold their experience with more relevant curricula that connects with their classroom experiences. He also wondered how professional learning and their implementations might help teachers for enhancing experience related to relevance. Listening to Mr. John's conversation, Ms. Becky, talked about the result of those interventions and how it can impact the classroom.

> Absolutely. And I think just techniques to incorporate some of these other pieces to help teachers make sure that all students are participating in, are able to connect to whatever it is that's going on. And also making it relevant too like, are we talking about an issue that the students can connect to that has a part of their normal life? (Ms. Becky, Round I)

Ms. Becky stressed on the importance of making sure that students contribute and make lessons relevant to their lives, and how instructional coaches can help teachers in facilitating these roles. Ms. Becky also narrated how student experience can be an opportunity for teachers to learn more and improve classroom environment while interacting with the Choropleth Heat map visualization.

> I think this is a really cool opportunity for teachers to gauge their classroom and their students. Like you can see there's a relatively high participation going on in the class verbally, but then there might be some understanding issues that are happening in kid's heads. So, the teachers. But I think this is a really informative opportunity for teachers to say, okay, we might need to work on this a bit more. Or how do I encourage my kids to speak up. I think it's informative for the teachers themselves. (Ms. Becky, Round I)

Ms. Becky pointed out how this representation is providing an opportunity for teachers to hear and know students' inner voices that can totally be different from their behavior in the classroom and be useful to teachers. As interviewer asked Ms. Becky and Mr. John on what instructional need this points to as your role as district leaders and instructional coaches, Becky responded:

> A lot of teaching strategies, you know, you could do a professional learning experience based on each one of these questions. And focus just on pulling that out for the teachers. Have you really included this method of instruction? Or this piece of instruction. (Ms. Beck, Round I)

Ms. Becky and Mr. John both directed on understanding student experience data with different representations as opportunities for teachers to connect with their students. And how they can use targeted strategies with the teachers to meet the instructional needs of diverse and multicultural students. They noted that the engagement level of students tied with the success of students.

In summary, teachers we worked with cared about student experience related to coherence, relevance and contribution as much as they do about the content knowledge. Teachers know experience to be an integral part of academic success for students. Visualizations that disaggregated data by gender and race help them identify issues of equity in all instances, at least this was the case in our study. We found that these visualizations supported teachers to inquire about the experience of students and consider implications for instruction. They showed care for the experience of racially minoritized students and the experience of girls, and they valued student experience data that made this visible. However, how teachers can make use of this experience data related to coherence, relevance and contribution to enrich classrooms and student lives remains an underexplored and rich phenomenon. Visual learning analytic tools can be leveraged for the sake of supporting teachers' engagement with students' experience in the service of creating equitable and just learning environments.

Interpretability and recommendations

Teachers' reflection on the interpretability of visualizations showed us where their interests lie and informs user-centered design of the SEET system. Below we discuss two examples of teacher noticing and suggestions that helped in developing the user interface of the system.

Example No 1: Horizontally categorizing bar chart by gender and Race

When the interviewer posted a data display containing disaggregated vertical and horizontal stacked bar charts to Ms. Yarosh (Science Teacher) to elicit her thinking and understanding would she prefer a horizontal or vertical bar chart, she responded:

> And I'm wondering if they're bars stacked on top of each other. So that takes quite a bit of thinking to unpack what's happening there? Um in question three. Well, I would say that these could all be bars but proportioned out between lesson three A. So, a bar that is proportionally representative of 20%, and then one that would show stacks on stacks on top of each other, not on top of each other like this but next to each other. So, you get that quick visual like, woah 63%. A quick visual for each lesson, right? So, I think either way, I would like them portioned out per population. So, you could quickly see the smallest population or the largest percentage. (Ms. Yarosh, Round I)

Ms. Yarosh initially expressed her thoughts that vertically stacked bars categorized by each lesson are hard for her to interpret the differences across race levels. She suggested that rather than stacking race categories on top of each other vertically on a bar, she would place them next to each other for a quick comparison across student populations to quickly compare. This conversation and suggestion of the teacher led to the design of a horizontal disaggregated bar chart based on categories for gender and race, see figure 1.

Example No 2: Showing only "yeses" or correct responses facilitates comparisons.

A constructive suggestion by Ms. Yarosh shaped the design of visualization, as students were answering multiple choice questions that had three response options ('Yes', 'I don't know', and 'No'). During the first round, we displayed all three responses, conjecturing that it would help teachers identify patterns across the response types (Figure 4(A)). The yellow color represents the percentage of the class who said 'Yeses', Cyan represents 'I don't know', and Blue represents 'No', to a survey question based on a particular construct. Contrary to our expectations, teachers preferred visualizing only the 'yes' responses.

> So, I guess for me, this neutral choice doesn't necessarily give me the information I'm seeking. I would prefer it matters or it doesn't. (Ms. Yarosh, Round I)

Analyses of additional qualitative data suggested that displaying only the "yes" responses helped teachers to compare patterns across the three constructs; many instances teachers also showed that approach helped spark discussions about the low percentage of "yeses" answers from the students, as they perceived it a simpler solution for cross comparison across questions. This also facilitated cross comparison between constructs; coherence, relevance and contribution by pointing teachers' attention only to one value. The resulting visualization based on teacher feedback was a horizontal bar chart displaying only the 'yes' percentage only (Figure 4(B)).

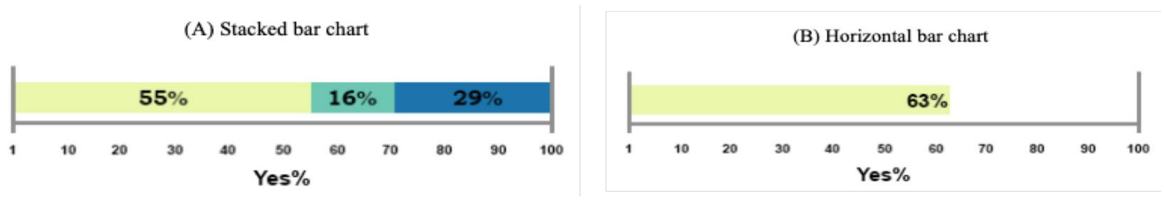

Figure 4: (A) Visualizing the student experience based on 'Yeses', 'I don't Know', 'No' (B) Visualizing 'Yeses' of the student experience

Discussion and conclusion

The main objective of this study was to provide insights from the design process of the Student Electronic Exit Ticket (SEET) system and teachers' thought process. We presented key teacher and instructional coaches' experiences that played a pivotal role in finalizing the visual feedback displays. A rich understanding of student experience should support teachers to modify their instructional or curricular agenda to better promote equity in the classroom. Along with the help of teacher partners, our team has designed and developed an exemplar application supporting 'Equity Analytics'. Shah and Reinholtz (2018) called for researchers to build tools and extend 'Equity Analytics' work with its applications to support equity across different disciplines. With the wide adoption of such tools, teachers can understand student experiences at scale to make classrooms equitable.

Our focus in this paper has been on analyzing how teachers perceive equity in the classroom when aided with visual learning analytics. We learned that it is imperative for researchers and system designers to have an open perspective when designing feedback dashboards and to deeply attend to teachers' perspectives and guidance in order to ultimately bring equity to the classroom in meaningful and relevant ways. The teachers' part of the study were from same school district and subject area (middle school science), a broader and more diverse group of teachers would be needed to further validate our findings.

Understanding student experiences can help teachers to shape classrooms to be more equitable by making them culturally relevant and sustainable (Paris & Alim, 2017; Brown, 2019), enabling all students to contribute and build on each other's knowledge. It is critical to quantify differences in students' classroom experiences in order to remove inequities based on characteristics such as gender and ethnicity. Ahn and colleagues (2019) discussed the value of using human-centered-design methods with teachers when designing instructor dashboards providing data on student learning. The aim of our design process was to apply such methods to explore how learning analytics tools can be adapted rather than adopted by teachers and to understand how the design process itself can foster new innovations in designing dashboards. Adapting these design methods influenced the design of the tool and helped with improvement efforts of supporting mathematics teachers. The dashboard helped to visualize patterns easily in data on experience for groups of individuals, such as individuals who are in the same classrooms in the context of their teacher-researcher partnership. Co-designing visual analytics with teachers can play an important role, providing help with interpretable data that enables them to make informed judgments about students' experiences and to modify their instructional practices accordingly. At the same time, preparing teachers to make sense of these data is not sufficient to promote equity, without consideration for systemic factors such as segregation, racism, and gender inequality in society--that help explain patterns of inequity in student experience data.

Creative Transfer and Domain-Specific Knowledge: The Effect of Prior Exposure

Jun Song Huang, Simone Ann D Souza
junsong.huang@nie.edu.sg, simone.dsouza@nie.edu.sg
National Institute of Education, Nanyang Technological University, Singapore

Abstract: The payoff of meaningful instruction is not just in the immediate retention of learned information, but also in transfer to novel situations in the future. This project focuses on what Haskell (2001) calls "creative transfer", the highest form of transfer of learning. 298 grade-five students from three elementary schools in Singapore took part in the study. This paper examines the extent to which the participants' *domain-specific knowledge* of the already-learned topics of *fraction multiplication* and *whole-number division* can predict their creative transfer to the untaught topic of *fraction division*. The data suggests that prior knowledge of whole-number division and fraction multiplication contributed significantly to creative transfer performance. Further analysis indicated that for participants who had less exposure to fraction division, their creative transfer was predicted by procedural flexibility for whole-number division, conceptual knowledge, and marginally by procedural knowledge for fraction multiplication. Implications for teaching and learning is discussed.

Keywords: creative transfer, domain-specific knowledge, whole-number division, fraction multiplication, fraction division

Introduction

Efficient learning involves the ability to acquire knowledge quickly while also being able to transfer the newly acquired knowledge beyond specific contexts and instances (Chang, Rosenberg-Lee, Qin, & Menon, 2019). Transfer occurs when prior knowledge is used to support new learning and problem solving (Sidney & Alibali, 2015). Creative transfer is regarded as the highest level of transfer in Haskell's (2001) taxonomy. It differs from other types of transfer as students need to expand, combine and adapt their knowledge in transfer to create novel concepts and procedures, rather than merely gaining the insight that something is similar to something else and applying knowledge across the two seemingly different contexts (Calais,2006).

In this paper, we study transfer by specifically looking at students creating new concepts or procedures from what they already know. As stated by Schoenfeld (1999), "we couldn't survive if we weren't able to adapt what we know to circumstances that differ, at least in some degree, from the circumstances in which we learned it" (p. 7). Calais (2006) provides an example, assuming a student has the prerequisite knowledge on the earth's uniform gravitational field. To explain what they feel when they stand in an elevator accelerating upwards, they need to create new concepts and procedures to explain the phenomena, for example, the concept and procedure related to the Principle of Equivalence for Einstein's Theory of General Relativity. The new concepts and procedures being created are built upon the student's existing knowledge, for example by expanding, integrating, and adapting existing knowledge in novel ways.

Transfer is important. The payoff of meaningful instruction is not just in immediate retention of the learned information, but also in transfer to novel situations in the future (Mayer, 1983). These situations may not be known to the present teachers and learners, so students need to be capable of dealing with creative transfer tasks that teachers do not (and could not) *directly* prepare them for.

Past studies (Carraher & Schliemann, 2002; Dunbar, 2001) suggest that even far transfer to isomorphic problems is hard to achieve (Duncker, 1945). Isomorphic problems (e.g., a pair of two-variable mathematics problems) embody similar relational structures and hence can be solved by transferring across a procedure or solution strategy. However, students often have difficulty recognizing the relational similarities between isomorphic problems. Bailin (1988) argues that even the most radically creative products, must be tied to the past (e.g., problems, representations, procedures, strategies, and concepts encountered before). Creative transfer is challenging because even if students can recognize the similarities and linkages between two problems, they still must combine and adapt their knowledge for transfer to take place. From a situated transfer (Engle,2006) perspective, transfer is promoted when a learner expansively frames the learning and transfer contexts.

Despite the challenges, transfer can take place spontaneously and effortlessly. In Forsyth's (2012) study, a physics undergraduate claimed that physics helped them understand many other subjects, such as the connection between basic principles in quantum mechanics and a pre-Socratic philosopher's concept of flow. Yet, Schoenfeld

(1999) notices that while we always adapt what we know to circumstances that differ, transfer is still "mysteriously absent from the psychological laboratory; it seems to vanish when experimenters try to pin it down" (p. 7).

A successful transfer requires identifying similarities between the source and target problems and an extension of knowledge to the target problem from a previously learned source problem (Gentner, Rattermann, & Forbus, 1993). Research indicates that both surface and structural similarities can influence transfer. Surface similarity is a similarity of features that do not influence goal attainment i.e. features that are not relevant to conceptual structure (Holyoak & Koh, 1987; Sidney & Alibali, 2017). Structural similarities are casual and conceptual relationships between the source and target problems (Holyoak & Koh, 1987; Sidney & Alibali, 2017). An example to represent this would be if we compare two scenes, one where a truck is towing a car and one where a car is towing a boat (Huang & Kapur, 2015). The structural similarity between the two scenes would be the towing of an object while the surface similarity would be the car (because both scenes used the same vehicle) (Huang & Kapur, 2015). Source and target problems that share a common structure will have a higher probability of transfer (Gentner et al., 1993). When the source and target problems have different surface features, it can be difficult for spontaneous transfer to occur (Day & Goldstone, 2012). Additionally, when source and target problems share surface similarities without structural similarities, negative transfer may occur (Chen & Daehler, 1989). One reason for these transfer challenges attributes to students' knowledge of the source problem, particularly when the structural features between the source and target problems have some variations (Dinsmore, Baggetta, Doyle, & Loughlin, 2013), as in the case of creative transfer.

This paper seeks to explore the relationship between domain-specific knowledge and creative transfer. Transfer literature states adaptive expertise provides the basis for transfer (Baroody, Feil, & Johnson, 2007; Schwartz, Bransford, & Sears, 2005). Adaptive expertise, often studied as procedural flexibility, is influenced by both conceptual and procedural knowledge (Baroody et al., 2007; Schneider, Rittle-Johnson, & Star, 2011).

Adaptive expertise is often studied in terms of procedural flexibility (Rittle-Johnson, Star, & Durkin, 2012) which refers to learners knowing multiple methods to solve a problem and being able to choose the best method for each problem (Rittle-Johnson et al. 2012, Schneider et al., 2011). Greater procedural flexibility is often associated with other forms of domain-specific knowledge such as conceptual and procedural knowledge. Conceptual knowledge increases the ability for flexibility and adaptability and provides a criterion to select for alternative possibilities for each step of a solution method (Hatano, 2003). Procedural knowledge provides a basis for procedural flexibility as it is the ability to solve problems (Schneider et al., 2011). Schneider and colleagues (2011) in their study related to the domain of equation solving noted that both conceptual knowledge and procedural knowledge contribute independently to procedural flexibility. While there is an understanding of the effect of these forms of domain-knowledge on procedural flexibility, creative transfer is more than just procedural flexibility. It involves not just flexibility in choosing methods but the creation of novel methods.

In the creativity literature, spontaneous transfer requires the creative generation of novel methods by expanding, combining, and adapting existing knowledge (Mumford, 2001). Domain expertise is found to influence these creative processes (Weisberg,1999). Typically, domain expertise refers to years of immersion in the field (Weisberg, 1999) or students' most recent grades in exams (Jeon, Moon, & French, 2011), like a mathematics exam result. The different types of domain-specific knowledge are not sufficiently differentiated nor measured in the existing creativity literature.

Considering these gaps in the literature, we work in the context of mathematics education to explore the effects of domain-specific knowledge on creative transfer. We operationalized domain-specific knowledge using measures of conceptual knowledge, procedural knowledge, and procedural flexibility. This study aims to understand the extent to which different types of domain-specific knowledge (i.e., conceptual knowledge, procedural knowledge, and procedural flexibility) on prerequisite curriculum topics, (i.e., whole-number division and fraction multiplication) predict students' performance in creative transfer (to fraction division).

Method

Research design and participants

A cross-sectional study was conducted with 298 fifth-grade students from three elementary schools in Singapore. The participants were previously taught the topics of whole-number division (in grade 3) and fraction multiplication (in grade 4). According to the participating schools' curriculum schedule, fraction division had not been introduced at the point of data collection.

Procedure, instruments, and reliabilities.

The participants' domain-specific knowledge on the topics of whole-number division and fraction multiplication and their creative transfer on the topic of fraction division were measured in the form of four pen-and-paper quizzes over three consecutive mornings (about 45 minutes each) in the participants' usual classroom setting.

The 9-item quiz for procedural knowledge was designed to measure the use of appropriate solution procedures for fraction multiplication and whole-number division questions. The overall reliability for this quiz is .92. The reliability of the subscales of whole-number division and fraction multiplication are .81 and .93, respectively.

Procedural flexibility was measured using a 5-item quiz administered on day 1. Marks were awarded for presenting multiple solution methods and the identification of the most efficient solution method, for fraction multiplication and whole-number division questions. The overall reliability for this quiz is .89. The reliability of the subscales of whole-number division and fraction multiplication are .84 and .87, respectively.

The measure for conceptual knowledge consisted of 6-item 'word problem' type questions. Answers had to be given through diagrams or written explanations, it was administered on day 2. The overall reliability is .65 and the reliability of the subscales on whole-number division and fraction multiplication are .39 and .64, respectively. Given the low reliability of the whole-number division subscale, only the overall measurement of conceptual knowledge was included in data analysis.

The creative transfer quiz was administered on day 3 and included 8-items, which focus on solving questions for fraction divide by a whole-number and fraction divide by a fraction. The reliability of the measurement is .77. A dichotomous question was included at the end of each item asking the participants how they came up with the answers. They could choose between the options of 'I have learned it before' and 'I invented it myself'.

The four quizzes were marked by two raters independently after some training. The inter-rater reliability of the four quizzes, in terms of Intra-class Correlation Coefficient (ICC), are 0.99, 0.99, 0.97, and 0.98, respectively.

Data analysis and findings

Pre-analysis

Initial descriptive analysis of the data was conducted to check the normality of the distribution of each measurement. The knowledge of whole-number division and fraction multiplication variables were created by summating all the items related to whole-number division and fraction multiplication across the first three quizzes. The descriptive statistics for the measurements and reliability (Cronbach's alpha) are presented in Tables 1 and 2.

Table 1: Descriptives for measurements and reliabilities of domain-specific knowledge and creative transfer

Quiz (Reliability)	*M*	*SD*	Maximum	Minimum	Full score
Procedural Knowledge (PK) (.92)	12.42	3.86	15	0	15
PK – whole-number division (.81)	1.49	0.80	2	0	2
PK - fraction multiplication (.93)	10.93	3.51	13	0	13
Procedural Flexibility (PF) (.89)	12.60	6.79	33	0	No upper bound
PF – whole-number division (.84)	2.93	2.69	11	0	No upper bound
PF - fraction multiplication (.87)	9.68	5.03	24	0	No upper bound
Conceptual Knowledge (CK) (.65)	3.19	2.54	13	0	26
Creative Transfer (CT) (.77)	4.80	4.65	21	0	22

Table 2. Descriptives for measurements and reliabilities of different prior-knowledge domains

Knowledge domain (Reliability)	*M*	*SD*	Maximum	Minimum
Knowledge of whole-number division (.92)	6.59	4.20	22	0
Knowledge of fraction multiplication (.89)	20.65	7.69	37	0

The scores for the procedural knowledge measure were positively skewed. This may be because Singapore students are generally strong at procedural knowledge. Furthermore, our concern was on whether the participants could use the procedures accurately, so the marking of procedural knowledge was based on method marking (i.e., whether appropriate procedures were used). Errors in arithmetic calculations were not penalized. The scores for the conceptual knowledge measure had a negative skew. Since the participants had not been formally taught fraction division at the point of data collection, students generally did not do very well in the creative transfer tasks. Given the violation of normality in the data, robust variants of statistical tests were used for analysis.

Students' prior exposure to fraction division

For the creative transfer task (i.e., fraction division), we noticed that the participants used a variety of solution methods, including the invert-and-multiply method which is the most common method taught to solve fraction division. This informed us to consider the participant's level of prior exposure to fraction division, despite the topic not having been introduced in the students' school curriculum at the time of data collection.

Participants were asked to answer the dichotomous question 'How did you come with this explanation?' at the end of all 8-items of the creative transfer instrument. Based on participants' responses to the dichotomous question: (i.e., 'I have learned it before' or 'I invented it myself'), we were able to divide the participants into three different groups based on their level of prior exposure to fraction division. For the *more-exposure* group (N = 70, M = 6.41), the participants responded in all the dichotomous questions that they had learnt the solutions before. For the *no-exposure* group (N = 14, M = 2.57), the participants responded in all the dichotomous questions that they invented the solutions by themselves. For the *less-exposure* group (N = 209, M = 4.53), the participants' responses were mixed (i.e., some solutions were learnt, and some solutions were invented).

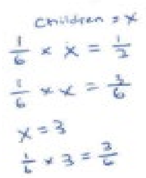
We analysed the difference between the groups using a robust variant of one-way independent ANOVA and a bootstrap post-hoc test (using the WRS2 library on R; Mair & Wilcox, 2020). The results indicated that there is an overall significant difference between groups (F_t = 7.94, p < .01, ξ =.45) The post-hoc test states that there was a significant difference between the *more-exposure* group and the *no-exposure* group (Mean difference = 5.45, 95% CI [0.92, 7.51], p < .01). There was also a significant difference between the *more-exposure* group and the *less-exposure* group (Mean difference = 2.78, 95% CI [0.54,4.51], p < .01). There was no significant difference between the *no-exposure* and *less-exposure* groups.

Methods used for creative transfer

We categorized the solution methods used by participants for creative transfer. Overall, we identified five categories of solution methods: invert-and-multiply, working backwards (see Figure 1), equivalent fractions (see Figure 2), study smaller and miscellaneous methods.

For the 'working backwards' method participants solve the fraction division problem by treating it as a reverse of fraction multiplication. For the 'equivalent fraction' and 'study smaller' methods the fraction (in the question) is converted to an equivalent fraction so that the numerator of the dividend is divisible by the given divisor. The 'study smaller units' method uses diagrams to solve the equation while the 'equivalent fraction' method uses mathematical notation. The 'invert-and-multiply' method is the standard method that is typically taught in schools and miscellaneous methods were methods that could not be classified into any of the given categories.

Examples of the 'equivalent fraction' and 'working backwards' methods are given below:



Original

$$\text{ch}\,ildren = x$$
$$\frac{1}{6} \times x$$
$$\frac{1}{6} \times x = \frac{3}{6}$$
$$x = 3$$
$$\frac{1}{6} \times 3 = \frac{3}{6}$$

Reproduced

Figure 1. 'Working backwards' original and reproduced response

Original

$$\frac{1}{3} \div 4$$
$$= \frac{1 \times 4}{3 \times 4} \div \frac{4}{1}$$
$$= \frac{1}{12}$$

Reproduced

Figure 2. 'Equivalent fractions' original and reproduced response

Since the invert-and-multiply method dominates formally taught procedure of fraction division (Slattery & Fitzmaurice, 2014), it is a good indicator of students' prior exposure to fraction division. Analysis indicates that the percentage of individuals who used the invert-and-multiply method *correctly at least once* was 60% for the *more-exposure* group and 37% for the *less-exposure* group. It should be noted that despite prior exposure, the participants' performance in creative transfer is rather low (i.e., out of a full score of 22, the means for the *more-exposure*, *less-exposure,* and *no-exposure* groups were 6.41, 4.53, and 2.57 respectively). It suggests that the participants' exposure to fraction division and the formal method of invert-and-multiply was very limited.

The extent to which prior knowledge influences creative transfer

Boostrap regression analysis (Using SPSS) was conducted to investigate the effect of prior knowledge on creative transfer. Overall, prior knowledge in whole-number division and fraction multiplication were significant for creative transfer. The prior knowledge accounted for 29% (R^2 = .29, adjusted R^2 = .28) of the overall variability. Whole number-division (β = 0.39, p < .01) and fraction multiplication (β = 0.22, p < .01) were significant in predicting creative transfer, the unique attribution (sr^2) for these variables was 11.3% and 3.5% respectively.

Analysis was conducted to understand the extent to which prerequisite knowledge predicts creative transfer for the *more-exposure* and *low-exposure* groups. We decided to omit the *no-exposure* group from further analysis due to low sample size (N = 14).

The overall regression model for both the *more-exposure* and *less-exposure* group was significant in predicting creative transfer, they accounted for a significant 22% (R^2 = .22, adjusted R^2 = .19) and 31% (R^2 = .31, adjusted R^2 = .31) of the variability respectively. The *more-exposure* group had an effect size of medium to large (f^2=.28) and the *less-exposure* group had a large effect size (f^2=.46).

For the *more-exposure* group knowledge of whole-number division (β = 0.30, p = .02) significantly predicted creative transfer, the unique attribution of (sr^2) of this variable is 6%. For the *less-exposure* group the knowledge of both fraction multiplication (β = 0.21, p < .01) and whole-number division (β = 0.43 p < .01) significant predicted creative transfer scores, the unique attribution of (sr^2) of these variables is 3.3% and 14% respectively. The results are summarised in the table below:

Table 3: Summary of multiple regression analysis for prerequisite knowledge predicting creative transfer

Level of exposure		*B*	*β*	*Sig.*	95% Confidence Interval	
					Lower	Upper
More-exposure	Knowledge of whole-number division	0.32	0.30	.01	0.06	0.59
	Knowledge of fraction multiplication	0.17	0.24	.09	-0.03	0.37
Less-exposure	Knowledge of whole-number division	0.46	0.43	.00	0.29	0.61
	Knowledge of fraction multiplication	0.12	0.21	.00	0.05	0.19

The extent to which types of domain-specific knowledge predicts creative transfer

Bootstrap regression analysis (Using SPSS) was conducted to understand how different types of domain-specific knowledge predict the participants' performance in creative transfer. The results are summarised in Table 4.

For the *more-exposure* group, all the specific types of the domain-knowledge (procedural knowledge, procedural flexibility, and conceptual knowledge) were non-significant predictors.

For the *less-exposure* group the overall model accounted for a significant 32% (R^2 = .32, adjusted R^2 = .30) of the variability in creative transfer performance (F(3,92) = 14.60, p < .01), with an effect size of f^2 = .47 which is considered a large effect size. Procedural flexibility for whole-number division (β = 0.19, p < .04) and conceptual knowledge (β = 0.31, p < .01) significantly predicted creative transfer. The unique attribution (sr^2) of these variables is 2% and 8% respectively. Procedural knowledge for fraction multiplication was marginally significant (β = 0.12, p = .05).

Table 4: Summary of regression analysis for different types of domain knowledge predicting creative transfer

Level of Exposure		*B*	*β*	*Sig.*	95% Confidence Interval	
					Lower	Upper
More-exposure	Procedural Knowledge (whole-number division)	0.08	0.01	.93	-1.67	1.88
	Procedural Knowledge (fraction multiplication)	0.17	0.10	.46	-0.40	0.59
	Procedural Flexibility (fraction multiplication)	0.14	0.14	.37	-0.24	0.52
	Procedural Flexibility (whole-number division)	0.38	0.22	.12	-0.09	0.88
	Conceptual Knowledge	0.35	0.19	.10	-0.04	0.92
Less-exposure	Procedural Knowledge (whole-number division)	0.49	0.09	.22	-0.27	1.29
	Procedural Knowledge (fraction multiplication)	0.15	0.12	.05	-0.01	0.29

	Procedural Flexibility (fraction multiplication)	0.08	0.09	.32	-0.07	0.25
	Procedural Flexibility (whole-number division)	0.33	0.19	.04	0.04	0.63
	Conceptual Knowledge	0.55	0.31	.00	0.31	0.78

Discussion

The main aim of this study was to understand the effect of domain-specific knowledge on creative transfer. This aim was operationalized by measuring domain-specific knowledge – specifically procedural knowledge, procedural flexibility, and conceptual knowledge- on the prior knowledge of whole-number division and fraction multiplication and creative transfer to fraction division. While fraction division had not been introduced by schools, the participants might have gained some prior exposure through external and informal sources such as tuition. Based on prior exposure to fraction division, the participants were divided into *more-exposure*, *less-exposure,* and *no-exposure* groups.

While the *more-exposure* group's performance in fraction division might largely be due to their prior exposure, we propose that the *less-exposure* group's performance was mainly due to their creative transfer effort. Firstly, on average, the *less-exposure* group only scored 4.53 (out of 22), suggesting that their knowledge of fraction division is far from satisfactory. Furthermore, about two-thirds of the participants in this group could not correctly use the invert-and-multiply procedure, even once.

Secondly, we know that the formal teaching of fraction division often focuses on rote memorization of the invert-and-multiply procedure without developing a clear understanding of the concepts (Sharp & Adams, 2002). If the *less-exposure* group worked on the fraction division questions mainly based on what they learnt about fraction division, they would not need to draw on their prior knowledge (e.g., procedural flexibility for whole-number division). However, this was not the case in the regression model of the *less-exposure* group, which shows that procedural flexibility for whole-number division and conceptual knowledge significantly predicted their performance in fraction division, while procedural knowledge for fraction multiplication was marginally significant. In contrast, the regression model for the *more-exposure* group reveals that none of the specific types of prior domain-specific knowledge predicted the *more-exposure* group's performance in fraction division. This implies that when students have a better mastery of fraction division through formal teaching with rote memorization, they could rely on their memorized invert-and-multiply procedure rather than draw on specific prior domain-specific knowledge (such as conceptual knowledge on whole-number division and fraction multiplication).

Our findings affirm the literature for the transfer from whole-number division to fraction division. A study by Sidney & Alibali (2015) finds that being exposed to whole-number division right before learning the invert-and-multiply procedure for fraction division, leads to higher conceptual understanding of fraction division. Our findings reveal that for the *more-exposure* group, their knowledge on whole-number division predicted their performance in fraction division, even though no specific type of knowledge (e.g., procedural flexibility) on whole-number division was significant. The findings highlight that students who had better knowledge of whole-number division would learn fraction division better (in their prior exposure to fraction division). Our findings on the *less-exposure* group further highlight that when students do not have strong prior exposure to fraction division, their procedural flexibility of whole-number division is particularly useful for transfer in inventing novel solutions to fraction division problems. From a situated perspective of transfer, it is integral to frame specific knowledge concepts as part of larger concepts (Engle, 2006). This encourages students to apply what they have learned to intuitively create new concepts (Engle, 2006). Students may have been exposed to the idea that mathematical concepts are linked and used that knowledge to apply their existing knowledge to fraction division.

We also underscore the importance of procedural knowledge on fraction multiplication in the transfer to fraction division. The literature regards the transfer from whole-number division to fraction division as an analogical one and argues that the similarity between fraction multiplication and fraction division is merely at the surface level (Sidney & Alibali, 2017). In our study, the procedures created by the participants (see Figures 1 and 2) reveal the integration of fraction multiplication operations into the novel methods. In Figure 1, students used fraction multiplication for equivalent fraction (i.e., $\frac{a}{b} = \frac{a\times c}{b\times c}$), and in Figure 2, students transferred the fraction multiplication operation (i.e., $\frac{a}{b} \times \frac{c}{d} = \frac{a\times c}{b\times d}$) to fraction division ($\frac{a}{b} \div \frac{c}{d} = \frac{a\div c}{b\div d}$). We argue that in both figures, particularly in Figure 2, the procedure of fraction multiplication is not merely a surface feature, but an important structural feature (in addition to whole-number division) to be mapped and transferred with adaptation (e.g., adapting from multiplication to division) to solve fraction division problems. Inferring from the regression model for the *low-exposure* group, successful adaptation requires good conceptual knowledge on whole-number division and fraction multiplication.

While the literature tends to conceive the transfer from whole-number division to fraction division as analogical transfer (Sidney & Alibali, 2017), we recognize the structural relevance of fraction multiplication for transfer to fraction division. Transferring of whole-number division knowledge is necessary but not sufficient for creating novel procedures to solve fraction division problems. The transfer, integration, and adaptation of fraction multiplication operations (as opposed to other fraction operations, such as fraction subtraction) is also critical. Hence, we propose that using creative procedures to solve fraction division problems involves creative transfer, which requires creatively integrating whole-number division procedures with fraction multiplication procedures and adapting them to create novel methods (as shown in Figures 1 and 2).

A major limitation for this study is the lower reliability of the measurement of conceptual knowledge compared to other instruments (Cronbach's α =.65). In the literature, the measurement reliability of conceptual knowledge always suffers from the absence of a proven reliable instrument (Rittle-Johnson & Schneider, 2014). Future studies may need to consider refining the instrument. Additionally, there was a low sample size for the *no-exposure* group, which led to its exclusion from analysis. For future studies, a pre-assessment of prior exposure to the transfer domain may be beneficial to ensure balanced group size.

This study has implications for the teaching of domain-specific knowledge in preparing for creative transfer. First, it is noted that fraction division is not in the Grade-5 curriculum and most likely, the participants gained their exposure through tuition, which primarily favors rote memorization of the invert-and-multiply procedure (Sharp & Adams, 2002). As shown in the regression model for the *more-exposure* group, rote memorization would discourage making use of prior knowledge and tends to create knowledge in silos. In comparison, when students with less exposure to fraction division are given a chance to create their own novel procedures, better connections of knowledge would be developed in the process of creative transfer. Hence, in practice, whether in schools or tuition, giving students a chance for creative transfer would allow them to benefit from their inherent creativity, and would improve their ability to cohere their knowledge. Second, there is increasing advocacy for the development of students' conceptual knowledge and procedural flexibility (Heinze, Star, & Verschaffel, 2009) in the literature; our findings support this sentiment. We advocate for more focus on developing students' conceptual knowledge and procedural flexibility, which would not only benefit their learning of the current curriculum topic but will also prepare them better for creative transfer in the future.

Abstract: Business giants collect and analyze personal data on a massive scale, including those of children's, to predict behavior and inform algorithmic decision-making. Such efforts reflect a form of "biopower", allowing control over other people, whose data are exploited. To safeguard children's data rights, scholars call for the need to empower children through critical data education. In our work we seek to understand how children can be empowered to reflect on the use of their own self-tracking devices and gain a deeper understanding of the political economy. This paper describes the design-based research process of designing an educational intervention that employed the use of activity trackers by elementary school students. This effort helped us peel back the layers of children's understanding of their own digital traces and supported their engagement in critical discussions. The paper concludes with lessons learned from the implementations on developing learning materials to foster critical data literacy.

Keywords: critical data literacy, personal digital data, design-based research, data privacy, self-tracking

Introduction

In an age when almost all dimensions of our lives are constantly digitized and datafied, concerns have been raised about the detailed personal information that is continuously generated through ubiquitous technologies. The term "datafication" is often used in the literature to describe how people's daily activities, practices and sensitive personal data are turned into digital information (Van Dijck, 2014). "Dataveillance" as a result of constant datafication, is the tracking and use of data for the purposes of monitoring people's activity (Van Dijck, 2014), and often happens through opaque algorithmic techniques. Such techniques collect and store people's personal information in large datasets, giving rise to Big Data accessed and exploited by third parties. Lupton (2020) explains two uses of personal data by third parties: (a) Collection and use of personal data to improve or market products or sell them to other companies for other types of exploitation, and (b) User profiling to inform the process of algorithmic decision-making with the support of artificial intelligence and deep learning models.

Scholars argue that this algorithmic decision-making has started to "unbalance" civil society, since it is used to sort and categorize individuals based on their data profiles (Pangrazio & Selwyn, 2020). Such categorization may have negative impact on individuals, including children, and may be unjustly used to exclude citizens from future opportunities. This data profiling and algorithmic decision-making is characterized in the literature as a form of soft "biopower" which affects individuals through a series of dividing practices manifested within relations of power by governments, business giants and other authorities (Lupton 2020; Pangrazio & Selwyn, 2020). Foucault discussed the issue of biopower long before the digital age as a means to control people through their personal information. Nowadays, these control practices can lead to the stratification and categorization of citizens based on data profiling (Pangrazio & Selwyn, 2020) because individuals lack the necessary knowledge and skills to identify where, how and why their personal data are being collected, stored, monetized and manipulated by others (Livingstone, Stoilova & Nandagiri, 2019; Pangrazio & Selwyn, 2020). This form of biopower affects children in a significant manner. As children and youth are constantly connected to digital devices, they become producers of a vast amount of personal data. Collecting, processing and assessing information on appearance, growth, development, health, social interactions, moods, behaviors, educational achievements and other features, without the consent of the children and, on several occasions, of their guardians, undermines their rights (Lupton & Williamson, 2017) and jeopardizes their future.

Scholars suggest that researchers and educational designers should focus on how to empower students and youth through critical data education and the development of critical data literacies (Pangrazio & Selwyn, 2020; Stornaiuolo, 2020). Children and youth's education about critical data literacy is necessary for developing the data skills to navigate in a datafied culture and see themselves as people with data rights (Stornaiuolo, 2020). Nonetheless, the kind of pedagogical support needed to empower students for recognizing, understanding and acting on their data practices should be further explored (Stornaiuolo, 2020). This study continues work reported by Agesilaou and Kyza (2021) on upper elementary school students' awareness of digital personal data, feelings of ownership of digital data and their understanding of privacy risks; informed by this work, this paper reports on how these findings informed the iterative design of a scaffolded inquiry environment designed to engage students in critically discussing about personal digital data in a formal educational setting.

Literature review

Empowerment through critical data literacy

Philip, Schuler-Brown and Way (2013) highlight the importance of "empowering students with knowledge" (p.106), to help students understand the role of their personal data contributions to the big data industry and exert control over the commercial exploitation of their data by third parties. Livingstone, Stoilova and Nandagiri (2020) discuss the difficulty of empowering children via personal data literacy because of the complexities involved in data protection and privacy regulations. They argue that learning how to navigate the contemporary digital landscape in terms of privacy is necessary but not sufficient to protect and empower children (Livingstone, Stoilova & Nandagiri, 2020). What is needed for children to ensure their data rights in a datafied society is a deeper critical understanding of the digital environment behind the digital interface, including the social relations and interactions that are embedded within it and which drive the emergence of the current business models (Livingstone, Stoilova & Nandagiri, 2020).

The idea of helping students acquire informed understanding of the massive dataveillance of everyday activities and be able to act based on this understanding has its roots in Paulo Freire, who talked about deliberate education in which teachers are not the authority, and students have the opportunity to question their reality and assume an active role in changing their society (Freire, 1970). This pedagogy supports students' opportunity to make decisions and act as agents of change in a datafied society, through the adoption of protective and resilient behavior towards the exploitation of their digital traces. It is of paramount importance to explore the extent to which students understand their personal data practices and the implications these have in the big data era. Such understanding will inform current efforts on how to better guide children through education for consciously being involved in practices that lead to the generation of personal and sensitive digital data. Such approaches have been reported as missing from contemporary education (Pangrazio & Sefton-Green, 2020).

Pangrazio and Sefton-Green (2020) discuss how data literacy approaches reported in the literature have been implemented in educational settings. They first note that research on data literacy pedagogy is limited. A conclusion derived from their study is that current data literacy efforts are unable to capture the range of skills and dispositions needed to tackle datafication and that the term needs more theorization to address a more critical and practical approach (Pangrazio & Sefton-Green, 2020). Pangrazio and Selwyn (2020) suggest that a critical data education should reflect the following objectives: (1) "Developing understanding of datafication processes, especially around what becomes a 'data object', how it is processed and used; (2) Critically reflecting on the importance of metrics in social media use, and the significance of numerisation in society; (3) Developing awareness and understanding of the political economy of digital platforms, including the capacity to track, profile and predict; (4) Identifying how digital platforms (including the interface and design) position users and shape their participation; (5) Identifying and using a range of strategies and tactics to protect their personal data; and (6) Gaining a sense of the longer-term implications of personal data practices" (Pangrazio & Selwyn, 2020, p.6).

Children's awareness of data privacy and third-party exploitation

Children are immersed in a variety of social networking activities that entail the disclosure of personal information. According to Livingstone, Stoilova and Nandagiri (2019) the full complexity of children's privacy online can be captured by three main types of relationships: between an individual and (i) other individuals or groups ('interpersonal privacy'); (ii) a public or third sector (not-for-profit) organization ('institutional privacy'); or (iii) a commercial (for- profit) organization ('commercial privacy'). In addition, Livingstone et al. distinguished between the types of data being shared online: (a) *Data given* by the individuals knowingly during their online media consumption, (b) *Data traces*, which are data left online, most of the times unknowingly, and are captured from data-tracking devices or plug-ins such as geolocation, cookies, etc., and (c) *Inferred data* which are created from the combination of the two former categories, using algorithms leading to the profiling of the data subjects. The inferred data fall into the category of commercial privacy. According to Livingstone, Stoilova and Nandagiri (2019) much less research has been focused on inferred data.

Research on children's online practices shows that their online media consumption has dramatically increased, even though children are reported to lack the necessary understanding and skills to securely navigate the digital environment. According to a survey conducted with 5,436 Canadian students in grades 4-11(Steeves, 2014), 32% of students in grades 4-6 have a Facebook account and 16% have a Twitter account. Steeves also examined students' privacy attitudes towards strangers and marketers. A large percentage of students (39%) stated that companies are not interested in what they do online, and 68% believed that if a website has a privacy policy, it means they will not share students' personal information with others. Livingstone, Stoilova and Nandagiri (2019) reviewed 105 empirical research studies from countries around the world, to assess students' skills in regulating their online privacy and the level of their understanding of the commercial use of their personal data. Children, ages 11-16, are reported to have difficulties in understanding the concept of personal data, have gaps in their knowledge and awareness of issues surrounding their online privacy and display a general inability to see how their data might be valuable to anyone (Livingstone et al., 2019).

Chi, Jeng, Acker and Bowler (2018) argue that in order to understand teens and their interactions with data, a holistic approach should be followed concentrating not just on behaviors, but also on the interplay of behavior with cognition and affect. They investigated how youth (aged 11-18) feel, think and behave in regard to their personal data online employing the Affective-Behavioral-Cognitive (ABC) model of attitudes. They found that young people were confident about their digital skills when using technology and were favorable towards having total control over their personal data. At the same time, they showed fear or anger when talking about who could access their online data, and the loss of empowerment and control over their digital data. These results, though, refer to students' perceptions, not their actual skills. The study participants showed a lack of awareness of what data were released to other entities, and how this might affect them.

Ey and Glenn Cupit (2011) interviewed children five to eight years old to examine their understanding of online risks, as well as their management strategies. In general, children identified several internet risks, but were unable to connect these risks with potentially dangerous situations. Specifically, when children were asked about placing their personal information on the internet, 54 out of the 57 children reported that it is not safe to give your name, address or photo on the internet. Similarly, Selwyn and Pangrazio (2018) ran a series of workshops with young people, ages 13-17, to explore their current understandings of personal data and data mining from third parties, and also to help them develop resistance practices. The findings of the study showed that the workshop activities were successful in making young people more conscious about their data trails, but less successful in cultivating the participants' need to act differently and employ resistance practices, such as using software to identify who might be tracking their personal data.

Such studies highlight the lack of young people's awareness of their personal digital data and the implications of their data actions online, but also expose the inability of young users to adopt protective and resilient practices towards the exploitation of their digital traces.

Research aim
This study is part of a design-based research project investigating upper elementary students' awareness of data privacy issues and psychological ownership of digital data. We are interested in understanding how students can be empowered through scaffolded inquiry experiences to reflect on their own personal digital data and gain a deeper understanding of the digital infrastructure and the political economy. Specifically, we focus on how the objectives of critical data education can be approached pedagogically, especially since the theory in this area is still evolving and research-based curricula are limited. Therefore, the main goal of this study was to analyze our design efforts to explore which pedagogical features have potential to scaffold students' critical discussions about personal digital data in formal educational settings. In this paper, we report on the design iterations and findings, and conclude with a set of empirically driven design guidelines for developing learning environments that can engage students in critical reflections on the uses of their personal digital data.

Methods

Theoretical foundations of the learning environment
The design of the learning environment was informed by Freire's critical pedagogy ideas and critical data education, as discussed in Pangrazio and Selwyn (2020): the goal of the designed materials was to scaffold students in understanding their personal digital data contributions and empowering them in making decisions based on their own values. The learning environment is also informed by critical theories of data literacy. The pedagogical approach for developing the curriculum is inquiry-based learning in an effort to engage students in authentic learning inquiries about their own personal digital data. Inquiry-based learning usually consists of five

phases: Orientation, Conceptualization, Investigation, Conclusion and Discussion (Pedaste et al., 2015). The inquiry-based learning approach has been chosen because it encourages Freire's view of education, since the learner in inquiry-based learning is expected to assume responsibility of their own knowledge-building process, and students' active participation is highly emphasized.

Design process

Learning materials aiming to foster critical data literacy are limited in formal educational settings (Pangrazio & Sefton-Green, 2020). The learning environment, developed for upper elementary students, was designed following a design-based research approach (Barab & Squire, 2004; Design-Based Research Collective, 2003), and implemented in two suburban schools. It was revised through two design cycles, which we report next. One of the main objectives of this learning environment was to develop activities that scaffold students in engaging in critical discussions and reflections of their own personal data. Towards this goal we developed a learning environment that employed the use of activity trackers by students. Activity trackers were chosen because they are popular smart devices with these ages and allowed students in our studies to unobtrusively generate their own personal digital data through physical activity. At the same time access to activity trackers is not usually prohibited in schools, as social media often are, thus making the alignment with the elementary school curriculum easier. Each student was provided with an activity tracker adjusted to his/her personal information (such as pseudonym, sex, year of birth, height and weight) after receiving signed informed consent by their legal guardians. Figure 1 presents an overview of the design cycle of the learning environment.

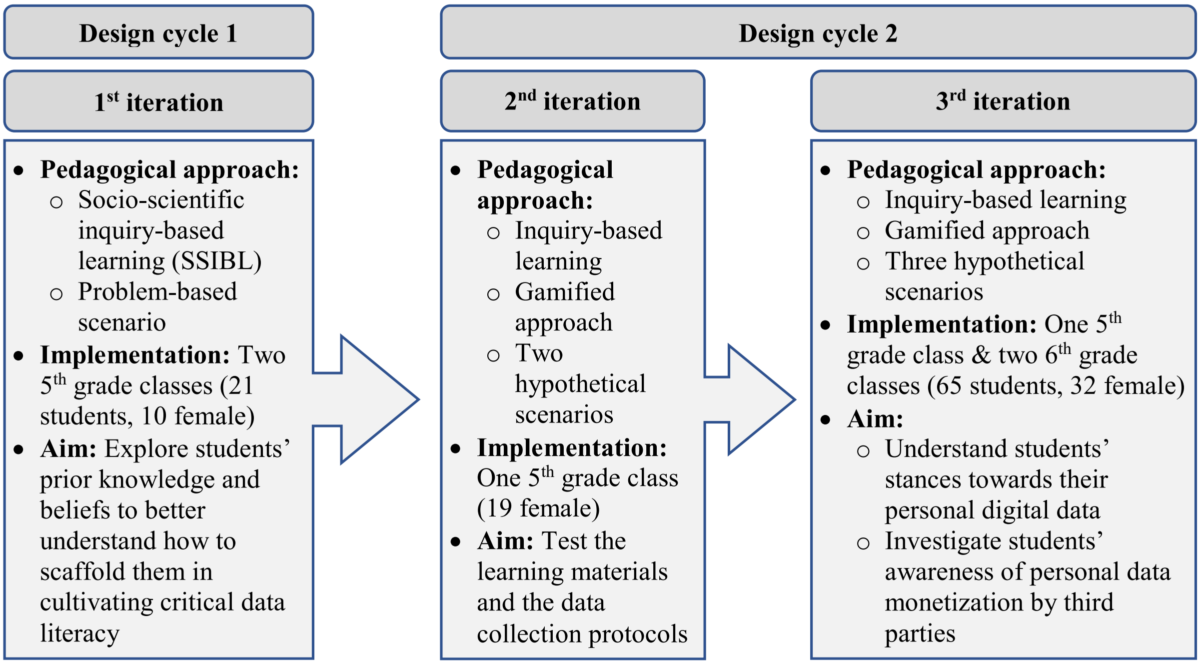

Figure 1: Design-based process of the learning environment.

Design cycle 1

Aim: Gain insights into students' initial understanding of the ethical dimensions and privacy issues related to using activity trackers and generating a vast amount of self-tracking data. We wanted to identify students' prior knowledge and beliefs to better understand how to scaffold them in cultivating a critical stance about personal digital data.

Implementation: The learning environment was implemented in two fifth grade classes with a total of 21 students (10 female). During the enactment students worked both individually and collaboratively, divided in four groups.

Approach: Socio-scientific inquiry-based learning, SSIBL (Levinson, 2018). The learning environment was structured around a driving question with students assuming roles of different stakeholders.

Learning sequence: An educational intervention that employed activity trackers and offered students the opportunity to collect and critically consider data from their own physical activity, was designed by a co-design team, with input from collaborating teachers. The module was designed for four 80-minute lessons. The first

lesson begins with a short, animated story ending with the driving question "Would you use an activity tracker to monitor your physical condition?" Each student was provided with an activity tracker, adjusted to his/her personal information, and performed a sequence of physical activities in the school yard. Students kept the activity trackers for three days to be used during school hours. The second lesson was about physical education and nutrition. During the third lesson, students discussed the graphical representations of their own physical activity data and assumed roles to investigate the pros and cons of using activity trackers as presented by the following stakeholders: companies who develop activity trackers; scientists and doctors; users of activity trackers; and insurance companies. The lesson ended with a debate between representatives of each stakeholder. During the fourth lesson, students discussed how the personal data from activity trackers are provided to third parties and what ethical aspects this might involve. Examples of the privacy policy and terms and conditions of various websites, including of the activity trackers' platform, were discussed.
Data collection and analysis: Data were obtained from video-recordings of three student groups during the third and fourth lessons which featured their own personal digital data discussions. Videos were carefully reviewed based on the critical incident technique (Flanagan, 1954) to identify incidents in which students had been engaged in critical discussions about the ethical dimensions and the privacy issues related to using activity trackers.
Findings: Students engaged in critical discussions about their self-tracking data. They believed that their data can be used by others, but most of them could not explain who these people might be. Students also believed that access to their self-tracking data by others is less important or serious as compared to someone having access to their conversations on social media. Even though we observed incidents of critical discussions in all groups, those reflected the opinions of some students. Not all group members participated in the discussions and this raised the question of how to scaffold each student in voicing their opinions on the matter. Similarly, during the debate activity, students identified arguments supporting their assigned stakeholder role, but these arguments did not reflect students' personal opinions and stances towards the use of their self-tracking data. We also noticed that students had difficulties in interpretating the graphical representations and in understanding their own data visualizations and needed further scaffolding to engage in such discussions.

Implications for design

The SSIBL pedagogical approach used in the first iteration was successful in helping students recognize the plurality of stakeholders involved in the issue in real life, and in helping us understand how students engage in collaborative discussions about the uses of personal digital data. In our next iterations, though, the aim was to develop learning activities that would be more personally meaningful to students and to give the opportunity to each student to shape the collaborative discussion. To address this goal, the SSIBL ethical dimension remained as the core of the learning environment, but we proceeded with the following revisions:

1. We decided that it would be better to have students at this age reflecting on their personal data rather than assuming roles of different stakeholders. In combination with their experience of using the activity trackers during the implementation, this would provide students with the opportunity to express their own personal opinions about the use of their self-tracking data.
2. Students were less engaged in some activities, so we decided to embed gamification elements in the learning environment to increase their motivation to participate. Using the ABC model of attitudes, activities were re-designed to attend to affective, behavioral and cognitive components of the task.
3. Based on findings indicating that students were not aware of who might use their personal data, we decided to design activities that would allow students to contextualize these ideas using multiple scenarios that resembled situations they may encounter in their personal lives. For this reason, we developed three hypothetical scenarios of specific companies asking for access to students' self-tracking data. We used these activities to help us gain additional insights about how students perceived the privacy of their personal data in actions (vs. based only on self-reported interview data).
4. We decided to keep the collaborative aspect of the learning environment and have students discuss in groups as the debate was important for externalizing ideas and highlighting the complexity of the situation; however, it was also important to encourage the participation of all students in the discussion. We, therefore, decided to scaffold the group decision making process in each scenario, by introducing an activity during which all students would first reflect on and articulate their personal opinion to the question raised in each hypothetical scenario.
5. We simplified the complex data visualizations and embedded them in the hypothetical scenarios to provide a meaningful context for interpretation.

Design cycle 2

Aim: With the second design attempt we aimed at gaining a deeper understanding of students' stances towards their own personal data in relation to online privacy and data monetization by third parties by increasing student engagement with the ideas both at an individual and at the group level.

Implementation: The learning environment was pilot tested in one fifth grade class of 19 students (8 female). After making necessary improvements, a revised version (third iteration) was implemented in one fifth and two sixth grade classes with 63 students in total (32 female) from the same school. During the enactments, students were divided in four groups per class.

Approach: Inquiry-based learning enhanced by gamification elements. Hypothetical scenarios were embedded in the learning environment to personalize the experience and invite students' reflections and critical discussion.

Learning sequence: The learning environment *"Who's looking at my data? Learning using activity trackers",* consists of three 80-minute lessons; the activity sequence progresses from familiarizing students with activity trackers through experiential activities (Lesson 1) to the exploration of three hypothetical scenarios presented and explored through a gamified approach (Lessons 2 & 3). In Lessons 2 and 3, students were presented with their mission: the director of a company that develops and sells activity trackers is asking for their help to reply to three requests, presented in three scenarios, about the release of students' personal tracking data. All three scenarios included information on: (a) the type of data being collected, (b) the requesting stakeholder, (c) the purpose of usage, and (d) the perceived benefits for kids. Our aim was to scaffold students in taking a position on each hypothetical scenario; we framed each scenario so as to highlight both the positive and the negative outcomes of conceding data ownership to empower students' impartial decision. The three scenarios were: (A) a sports company is requesting access to students' personal tracking data so that they can send them discount coupons and promotions based on their physical activities; (B) a health insurance company is asking for a girl's heart rate data to decide whether to cover medical expenses related to treating her heart disease, and (C) a children's gym owner gave each gym member a free activity tracker and is now asking for their permission to post their activity data on a members-only website for a monthly competition, with a free, one-month subscription to the gym as the prize.

Students in each class worked in four groups of six students each (12 groups in total). A progress map, showing start, middle and end points which the students should reach, was used to scaffold students' inquiry in each scenario activity. Each group had a unique logo chosen at the first lesson, and the progress map was updated with each group's achievements at several points during the investigation, by moving each group's logo to the current point. At the start line, students were asked to read the letter sent to the director. At the first station of the progress map, each student had to make an individual decision on what to advise the director. The individual decisions were followed by group discussion leading to an initial written group decision, as follows: *"We the (name of the team), advise the director of the company to respond (positively/negatively) to the sports company/insurance company/gym owner, because…"*. At the second station, students were provided with different data visualizations of the self-tracking data, according to each scenario, to scaffold their initial group decision. At the third and final station students had to declare their final decision, after examining the data visualizations they accumulated from the second station. After each scenario, all groups had to announce their decisions and provide evidence-based arguments. Plenary discussion followed to explore each group's arguments and explain the unanimity or the diversity of their decision.

Data collection and analysis: Data obtained from video-recordings from three student groups in each class (nine groups in total) during the second and third lesson, and semi-structured interviews obtained by all students before and after the learning interventions. Videos were carefully reviewed following the critical incident technique (Flanagan, 1954) to identify incidents in which students had been engaged in critical discussions about allowing or denying the companies in each of the scenarios to access and use their self-tracking data. During these episodes, we focused on how the learning materials and the resources made available to students had scaffolded or hindered their critical discussion. The interviews were analyzed using two coding schemes, reported in Agesilaou and Kyza (2021). The first coding scheme, which was based on the ABC model (Chi, Jeng, Acker & Bowler, 2018) and on Pangrazio and Selwyn's (2019) work, was used to identify students' Affective, Behavioral, and Cognitive states towards personal data privacy practices and to help us understand students' awareness of the commercial use of their personal digital data. The second coding scheme was used to identify students' conceptualization of ownership of their personal digital data.

Findings: The analysis of the video-recordings indicated that students were more engaged and motivated to participate in the collaborative discussions during the second design cycle which employed a gamified approach using a series of hypothetical scenarios. The hypothetical scenarios provided the opportunity to approach the matter from multiple angles; since they were neutrally framed they allowed students to express different points of view leading to interesting discussions. In contrast to the implementation of the first design iteration, students were more confident to collaboratively discuss the three scenarios and to provide their experience as users.

During the second design attempt, we guided students to examine the three hypothetical scenarios following the same steps, which were visible in the progress map placed on the blackboard. By the second and third scenario, students already knew how to proceed. This enabled each student team to continue on its own pace and allowed the teacher the opportunity to provide differentiated scaffolding to each team. Allowing students to track their progress, through the progress map, restructured the classroom organization between the teams and the teacher, but also between the members of each team. Even though students knew that there was no prize if they finished their inquiry steps first, they were monitoring the other teams' progress, and on many occasions asked their teammates to avoid off-task discussions and to contribute to the collaborative work.

The analysis of the interviews indicated that students would feel anger, fear, stress and be offended if someone gained access to their data without their permission. Our analysis revealed that students employ privacy and security mechanisms to their personal digital data to avoid data violations from hackers, hazardous communication with strangers and disclosure of geolocation information. While students' answers before the learning intervention, as to who might be interested in their personal digital data, were more general (e.g. hackers, strangers, for bullying purposes), after the learning intervention more (but still not all) students became more specific and reported that their data can be used by companies, highlighting the potential of our intervention to positively affect students' awareness of personal data mining. We also examined students' conceptualization of ownership of their personal digital data. The majority of students believed that they are the only owners of their data; only few students were aware that when giving permission to a commercial entity to access your data, one also agrees to shared ownership and shared rights about those data.

Implications for design

These results indicate that future efforts should focus on helping students acquire a better understanding of the transfer of data ownership to third parties, along with what happens with the data analysis and profiling of their personal data, in order to develop the necessary competencies to decide which privacy and security practices towards their personal digital data they wish to employ. The analysis of students' interviews and in-class group discussions indicated that students' willingness to concede data ownership to third parties is dependent on *the nature of the personal data being shared*, *how they will be used*, *by whom* and *for what purposes*. These criteria shaped students' decisions in the three hypothetical scenarios. Students were positive in conceding data ownership to the sports company (9/12 groups) and the insurance company (12/12 groups), but negative to conceding data ownership to the gym owner (9/12 groups). These results highlight that context is important on how students evaluate data privacy and how they perceive the commercial utilization of their personal digital data.

Discussion and conclusions

Design-based research serves twin and complementary goals: While it seeks to validate learning theories in real-world practice, it also contributes to the development of these theories (Hoadley, 2004). The goal of this design-based research effort was to design a learning environment for upper elementary students to support their understanding of the data economy and the commercial exploitation of their personal digital data. Informed by critical theories of data literacy, we designed and implemented a learning environment in order to understand how children and youth can be empowered through scaffolded inquiry experiences to reflect on the use of their own smart, self-tracking devices. Lessons learned from the two design cycles described in this study, show that the following design principles are important in shaping students' development of critical data literacy: (1) Contextualization is an important factor which can shape students' understanding of the exploitation of their personal digital data and foster engagement in critical discussions. There are four determinants of students' willingness to concede data ownership to third parties: the nature of the personal data being shared, how they will be used, by whom and for what purposes. The results of this study suggest that students evaluate shared ownership of personal digital data based on different criteria and this impacts their willingness to disclose or protect personal information, and their willingness to share data ownership with third parties. Future efforts should consider these criteria when designing learning materials aiming to foster critical data literacy. (2) Setting up a scaffolded, personally-motivating, critical inquiry context increases students' willingness and ability to engage with the ideas. In our study, it was important to support students' engagement with the, otherwise, abstract ideas of data privacy by connecting experiential activities with individual and group-level reflection. The gamified approach and task-driven activities fueled engagement, transforming the activity-trackers and the scenaria that were linked to them to evocative objects (Turkle, 2007).

Our ongoing work, of which this study is a part, also contributes to theory building about students' conceptualization of the psychological ownership of digital data, which has been less explored in the literature, and critical data literacy education efforts. Attending to the affective-behavioral-cognitive (ABC) components of the task increased students' critical discussions. Yet still, students in our study believed they were the only owners of their self-tracking data, even in the cases when they agreed to give access to their data to third parties, such as the companies presented in the three hypothetical scenarios. In order for students to develop critical data literacy, they have to gain a deeper critical understanding of the digital infrastructure, and how data flows from the individual devices and applications, to second and third parties managing those data. Such an understanding is necessary for students to realize the subsequent data transfers and data rights to others.

Efforts to design learning materials aiming to foster critical data literacy in formal education have been reported as limited in the literature (Pangrazio & Sefton-Green, 2020; Pangrazio & Selwyn, 2019). Our study is among the first efforts to understand how students can be scaffolded in developing the conceptual and practical competencies needed to gain a deeper understanding of the digital environment and the political economy. Such initiatives are important in contributing to the discussion of how critical data literacy can be theorized in formal educational settings and supported through empirically validated research-based curricula.

Abstract: Writing Data Stories is a social design-based research project to co-design and study data literacy units. The project encourages nondominant students to integrate everyday practices and scientific datasets by using storytelling and computational transformation to highlight personally and socially relevant issues. We present an analysis of one cycle of instruction where students pursued an unanticipated path of investigation—locating themselves on a map within a data analysis tool though the dataset lacked geographic information. A researcher initially considered this path to be unproductive, but changed focus as the teacher followed students' lead and encouraged exploration of the map in subsequent classes. Using conceptions of third space, we examine the sequence through which teachers and students co-produced a reorganization of the activity, power relations, and curriculum toward expansive data reasoning. We contrast this productive reorganization with marginalization of other student practices, identifying implications for curricular design and classroom research.

Keywords: data reasoning, third space, consequential learning, social design-based experiments

Introduction

Work exploring the importance, emergence and design of *Third Space* (Gutierrez, 2008; Gutierrez & Jurow, 2016) has centered primarily on supporting nondominant youth in informal learning contexts. In these informal contexts, educators have more flexibility than classroom teachers, and power relations between those involved—students, informal educators, researchers, and classroom teachers—tend to be more fluid. In contrast, in the vast majority of formal schooling contexts, students and classroom teachers must contend with institutional constraints of content standards and testing, without adequate support for more expansive approaches. Despite these challenges, the concept of Third Space has been used in school settings. For example, Gutiérrez et al. (1999), examined how teacher and student talk and knowledge in a science classroom were reorganized to create opportunities for authentic interaction and a shift in the social organization of learning. Like Gutiérrez et al.(1999), our work is also focused on Third Spaces in science classroom contexts. Using a design-based approach,we examine how student interests and exploration can drive curricular design and mediate a reorganization of student, teacher, researcher relations.

It is well recognized that STEM classrooms are often not supportive or encouraging spaces for nondominant youth (Martin, 2013; Bang, Warren, Rosebury, Medin, 2012). Prior research has used a Third Space lens on STEM in formal contexts, including work that has explored the merging of students' cultural repertoires of practice and social worlds with conventional STEM disciplines/practices (Barton & Tan, 2009), and that has focused on the development of relevant or relatable content (Barton, Tan, & Rivet, 2008; Moje, et al, 2004; Vick 2018). In our conceptualization, Third Space functions as a collective zone of proximal development (Gutiérrez, 2008; Vygotsky, 1978) or ZoPED (Griffin & Cole, 1984) wherein students and teachers co-construct knowledge in ways that reorganize the relation of everyday concepts and practices with scientific ones (Gutierrez & Jurow, 2016). In the context of design, the aim of supporting the emergence of a Third Space is to leverage resonances between scientific and everyday knowledge and practices that elevate nondominant students as sensemakers.

The Writing Data Stories project ("WDS"; IIS-1900606) seeks to develop and study curricular units that reposition the everyday knowledge and practices of youth of nondominant communities by placing that knowledge in direct conversation with scientific datasets and analytic practices such as data visualization, data transformation, and storytelling. A distinguishing principle in our work is understanding Third Space as a significant disruption to and reorganization of intellectual space, including a reorganization of what ideas and practices are valued, how they are linked, and whose linguistic and epistemic practices are privileged. Specifically, the project seeks to reconfigure students' relationships to data, which is often presented as an objective representation of reality that is granted higher epistemic status than other ways of knowing, including students' own experience (Bang and Medin, 2010). The project aims to elevate and weave the experiences of students from non-dominant communities *alongside and integrated into* scientific datasets, through students' use of computational "data moves" (Erickson, Wilkerson, Finzer, & Reischmann, 2019) to inscribe their own knowledge, experiences, and values into the datasets (for example, by adding foods or variables such as cost, taste, or accessibility to a nutrition dataset). Our project goal is to make a significant contribution to the research on Third Space by studying and identifying consequential data literacy approaches for nondominant youth. A Third-Space-designed data literacy project must contest deficit discourses and disrupt rigid authoritative practices and ideas, highlighting social and cultural dimensions to "objective" pre-existing datasets. In this way, the project enables a reorganization of classroom roles and the relationships between everyday practices and disciplinary reasoning about data.

The case we share here offers specific insight into how learning in a Third Space de-centers authoritative views of STEM as data experiences are co-constructed by students, teachers, and researchers. Third spaces emerge in contexts with histories of practice, as well as in moment-to-moment activity. Our overall analysis focused on multiple moments in which the tools and goals of a particular lesson were reorganized in response to students' unexpected interests. Importantly, this became a sight of significant learning for the research team and informed subsequent curricular design. In the analysis of the unfolding of this example, we highlight four phases of the reorganization and coproduction of this particular Third Space. The first phase entails a researcher-designed exploration activity that privileged everyday practices of students in collective knowledge production about the Common Online Data Analysis Platform (CODAP) and a nutrition dataset. The second emerged when students—afforded the open-endedness of exploration—reoriented toward map exploration and away from the nutrition dataset. The third phase occurred when the teacher, rejecting the researcher's initial advice, responded to students' unexpected interest in the map by reframing the exploration task to explicitly include the map as part of the object of inquiry alongside the nutrition dataset and other CODAP features. The fourth phase carried lessons learned from this brief cycle of instruction into longer-term design efforts as the curriculum team designed subsequent units to more centrally highlight the map tool as part of data inquiry. We also present a missed opportunity to co-construct Third Spaces with students who translanguaged as they made sense of data. Responsiveness to organically emerging productive data investigation, as well as to linguistically marginalizing dimensions that were later observed, were central to subsequent unit design.

Theoretical framework

This study explores the emergence of a Third Space wherein consequential data reasoning and curriculum design unfolded as a co-production of the teacher, students and researchers. Here, we briefly review theories related to Third Space and data reasoning to help ground these conceptualizations of learning and reasoning. The construct of a collective Third Space builds on an existing body of research and can be viewed as a particular kind of zone of proximal development. As an emergent and co-constructed environment, the Third Space is a particular social environment of development, in which students begin to reconceive who they are and what they might be able to accomplish academically and beyond. Learning in the Third Space has highlighted how its accomplishment is mediated by a range of tools and a reorganization in the hierarchies of classroom knowledge, as well as of the participation structures of more formal environments (Gutiérrez, 2008). In concert with the hybrid character of Third Space, consequential learning in the Third Space necessarily leverages both everyday (horizontal) and school-based (vertical) knowledge such that traditional notions of development generally defined along vertical dimensions (e.g., novice, competence) were challenged. Of significance, to this proposal, is that not only students, but the teacher and research team also began to jointly re-imagine and design for new curricular possibilities. As a social design-based experiment, this study's design also attuned to the co-participatory, iterative, and responsive potential of collaborative design and a shared practice (Gutiérrez & Jurow, 2016).

Our project seeks to support data reasoning as a way to understand both the world and oneself, and support Third Spaces in which new relationships between data, the world, and the self can emerge. Our conceptualization of data reasoning includes a number of practices central to data work, summarized by Rubin (2020) as: understanding the contexts in which observations are collected (and how valid/appropriate the data are for understanding a given system or situation); reasoning about mathematical features of the data including variability and aggregate patterns; flexibly visualizing data and understanding how they might be differently represented to reveal new trends and relationships; and drawing inferences from data back to the world. It also involves reasoning about one's personal relationships and situatedness relative to a given dataset and the systems it describes (Wilkerson & Polman, 2020), including locating or observing oneself within data; projecting self and community into aggregated social and historical data; and manipulating, critiquing, or generating datasets to better reflect one's own experiences. This case represents an instance in which we observed students engaging in many more personal, social, and representational explorations of data after a reorganization of activity co-designed by the students, teacher, and researchers.

Research questions

While the goals of the WDS project were to support the emergence of Third Spaces within the *classroom* as students worked with data, this cycle of instruction also reflects the emergence of a Third Space that extended into teacher-researcher relations and subsequent curricular design for supporting data reasoning. The cycle of instruction we report here involved new paths of exploration by students, and illuminated productive ways to reorganize goals, tool use, and researcher-teacher roles to enrich the coconstruction of curriculum. Given the power and implications this holds for curricular co-design efforts, it is important to better understand its emergence and how it was sustained. This yielded the questions:

1. How did the initial curricular goals in this cycle of instruction support the emergence of a Third Space in which relationships, roles and learning activities were reorganized to support students to use their everyday practices in data analysis?
2. What does this cycle of instruction suggest about how productive reorganization of the classroom activity system can be sustained over time?
3. How did this cycle of instruction inform future curricular design decisions and collaborative efforts?

Methodology

Our focal episode is drawn from a large corpus of data collected during our first, 21-day curricular enactment in multiple 7th grade class periods with a collaborating teacher we will refer to as Ms. Phillips. For each day of enactment, we captured audio-video recordings of whole-classroom interactions, audio and screen recordings of 2-3 focal groups of 2-3 students each per class, observer field notes, and audio-video recordings of mid-day debriefing sessions between researchers and the classroom teacher. We created activity logs, describing the general organization of activity for every 2 minute interval, from the whole-classroom and teacher debrief videos. We selected the events of Day 17 for deeper analyses after our codes helped us notice that multiple student groups demonstrated creative and unexpected data reasoning as they engaged with the data analysis tool on that day. After looking deeply at that student reasoning, we observed that it was grounded in how the teacher responded to an unexpected focus of students in the two periods she taught and observed earlier in the day. We chose to investigate this sequence of events more deeply as there seemed to be a significant reorganization of the intended classroom activity by the teacher and students.

Study context

Our episode is drawn from Year 1 of the WDS project, during which we engaged in collaborative curricular design and enactment with science teachers at a school that served predominantly Latinx, emergent multilingual middle school learners in California's Bay Area in the U.S. The first unit we co-designed focused on analyzing nutrition data about breakfast foods. The collaborating teacher saw the unit as an opportunity to extend work the class had previously done exploring the nutritional causes of diabetes, a health issue she felt was prominent in the community. In this unit, students reflect on and collect data on their own breakfast practices and the practices of family and friends. They then compare their personal and community practices with how breakfasts are described in advertisements. After critically reflecting on foods and values in ads, they explore a nutritional dataset about cereals and consider how it might be changed to better reflect the foods and factors that they care about (rather than only what's 'normalized') when choosing breakfast. Finally, students analyze and transform the dataset, including by adding new records and variables, using the Common Online Data Analysis Platform ("CODAP"; Finzer & Damelin, 2016). Based on an analysis of a now modified dataset, they identify and justify their own "ideal and accessible breakfast."

While designed to be accessible to middle school students, CODAP involves specific data representations and features that are novel to students. With this in mind, before students worked in the digital environment, we introduced some of the data representations they would encounter and be able to do by having students work in small groups with paper versions of different cereal nutritional fact cards (labeled "case" cards in CODAP). Students explored and compared the small set of approximately 5 printed nutrition fact 'cards' for cereals, adding written nutrition fact cards for their own foods, and annotating both the cereal cards and their own foods to include information about other important variables (e.g. cost, taste, accessibility). Thus, students had some experience with the nutritional data and data representations before exploring them in the CODAP digital format on the Day 17 cycle of instruction described below.

Analysis

We re-emphasize here our interest in Third Space at the curricular design and enactment level, as the emergence of a collective ZoPED in which new forms of learning are made possible through a fundamental reorganization of activity such that students coproduce their learning. In this analysis we describe four distinct phases of activity in which we observed this sort of reorganization along the lines of a collective Third Space as it unfolded across the classroom enactment and related curricular co-design.

Phase 1: Designed tool and dataset exploration put the map and data at odds

During the Day 17 cycle of instruction, students were first introduced in the digital environment to a nutritional dataset that included over 75 entries. The teacher and researchers had planned a day for students to openly explore the dataset and the CODAP environment. The goal was to help students develop confidence with the platform through centering students' interests and questions and elevating them as sensemakers. To do so, we included time for students to familiarize themselves with the larger nutrition dataset, and with useful features of CODAP including how to visualize and add new data and variables. The image to the left in Figure 1 provides an example of what we envisioned a student computer screen in CODAP would look like at the end of the exploration. The figure includes a nutritional "case card" for Maypo cereal and a graph of the sugar in all the cereals in the dataset. Given that geographical data was not a part of the dataset (note the blank map to the right of Figure 1), the teacher and researcher were surprised when a majority of students in the first two class periods reoriented from exploration with the nutrition data, and instead opened the blank map feature in CODAP to look for themselves. This move to position themselves in the map is consistent with research in data reasoning that students tend to first approach data in relationship to themselves (Kahn, 2020; Wilkerson & Laina, 2018).

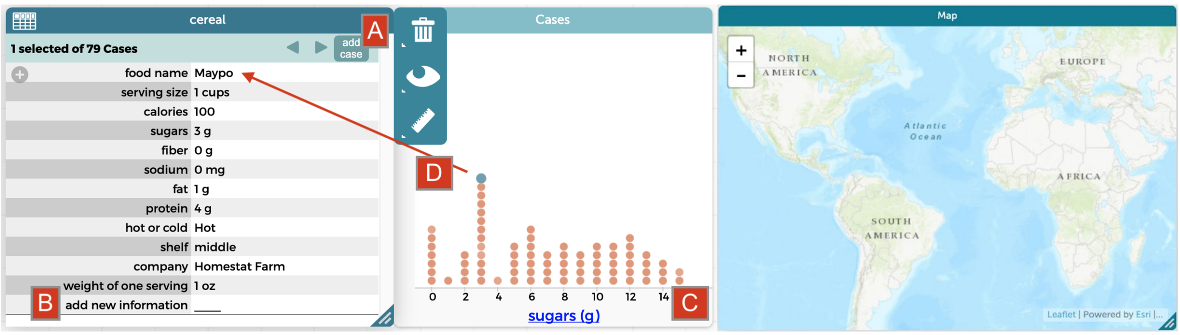

Figure 1. (left) CODAP environment with cereal dataset and anticipated features highlighted: add data (A), add variable (B), build graph (C), and selected data (D). (right) Map window in CODAP with no geographic data.

Phase 2: Teacher responsiveness to student interest in the map

After the first two class periods, during the mid-day debrief, the teacher and researcher discussed the unexpected and overwhelming student interest in the map. The researcher initially suggested redirecting students back to the cereal dataset and related CODAP functions, but the teacher wanted to support student interest. The teacher and researcher worked together to supplement an existing list of CODAP features on the whiteboard for students to explore (Figure 2, left side) with the prompts "any other helpful tool?" and "♡ How does the map represent your DATA STORY?" (Figure 2, right side). Her prompt on the board sanctioned use of the map and suggested that it could represent a "data story" that linked back to nutritional data.

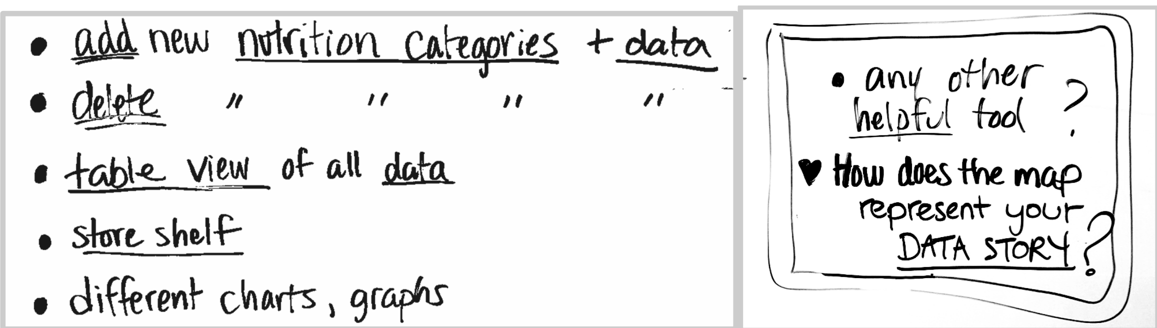

Figure 2. (left) Original CODAP exploration questions added at beginning of day. (right) Revised, map-focused exploration questions added to the board by Ms. Phillips after the mid-day debrief session.

During the debrief, Ms. Phillips' responsiveness as a teacher led her to reframe the task for class periods later that day. She felt that explicitly building on interest in the map would be generative for student learning. By leveraging student interest in the map, she encouraged deeper reasoning about data and students' use of evidence in scientific reasoning.

Phase 3: New conceptualizations of the dataset relative to the map

Following her decision to productively respond to student interest, in period 5, Ms. Phillips framed the map as a legitimate tool for exploration and investigation of data, health and nutrition. We observed unexpected consequential student data reasoning in two of our focal student groups. Initially they connected the nutrition focused dataset to the topic of diabetes and an organic interest in maps. Later they searched for evidence to support their claims that the map showed the location of people with diabetes. This path of inquiry, led to the development of a collective ZoPED wherein students co-constructed knowledge as they made a series of connections across prior investigations of diabetes and nutrition, personal interest in locating people on the map, and knowledge about how diabetes in lower income families may relate to the need to rely on inexpensive but sugar rich foods like cereal. Based on Ms. Phillips' reframing of the task in response to earlier interest in the map, several student groups began to reason about how nutrition related map might include geospatial information and patterns. Two of our focal groups proposed that the map could be a "diabetes map."

For example, one focal student pair in Period 5, upon exploring the map, speculated that it might provide a data visualization related to diabetes (which the class had studied earlier in the year). They spontaneously discovered the text box feature (Figure 3), and wrote reflections on important variables relevant to diabetes that were missing from the dataset. Ms. Phillips probed for specificity by asking what evidence they had to connect the map to diabetes rates. The pair wrote in the text box "I think the map could show where people with diabetes are around the world but we are looking for evidence." When they opened a graph window, it displayed a number of small dots scattered randomly. (This is a design feature, in which each dot represents an entry or "case" in the dataset which will be rearranged once the axes of the graph are defined by the user.) One student in this pair exclaimed upon seeing the scattered dots: "THESE probably are the people! The cases? [*mouse over scatterplot*] Like, the people?" Ms. Philips continued to encourage deeper exploration of how the data might be represented within different CODAP tools, asking "but are those dots on the map?" The pair looked for corresponding data points on the map, in the process reflecting aloud to each other about connections between geography, income, food access, and nutrition. They speculated that low income areas may be linked to higher cereal and sugar consumption, and thus higher diabetes rates. These ideas about a "diabetes map," which referenced units of study from earlier in the school year, connected geospatial information, reasoning about nutrition, and students' personal experiences in new, unexpected, and what we argue are profoundly productive ways. They also motivated these students to deeply consider what counts as a "case" and its "attributes" in the dataset, how data might be differently represented, and what the social context of the nutritional data might be; all fundamental components of data reasoning (Rubin, 2020).

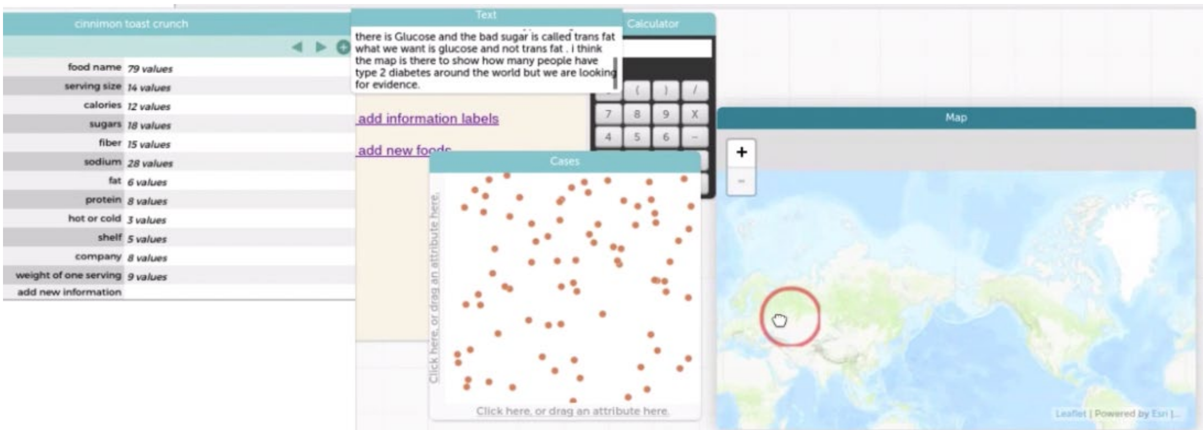

Figure 3. Screenshot featuring students' speculations about how nutrition related data might be visualized on a map. Their mouse click on the map is indicated with a red circle, and the text box reads "I think the map is there to show how many people have type 2 diabetes around the world but we are looking for evidence."

In working to reconcile the map with other features of the nutritional dataset and CODAP, this student pair deftly navigated a variety of tool features and potential data representations (case cards, scatterplots, and the map) as they worked to reconcile geography, broad views of nutrition, the more limited nutrition dataset, and their personal and social knowledge about how all of these might intersect. In the process, the pair also demonstrated several core elements of data reasoning: they worked to understand what counts as a *case* or observation in the dataset, especially as it might exist across multiple representations including geographic representations. In contrast to our intended explorations as highlighted in Figure 1, the investigation featured in Figure 3 is reorganized both in terms of how CODAP and its embedded tools are used (where a larger number and variety of tools are used), and in terms of the object of activity (which students expanded from a narrow comparison of nutrition facts about commercial cereals to instead consider how income affects consumers and how health is related to both geography and nutrition.

Another focal pair of students, similarly, began drawing connections between the nutrition dataset and broad themes of diabetes, geography, and visualization. As they opened and began to zoom and explore the map, one researcher approached the group to ask what they were doing. One student began, "We try to see how—" and the other continued "—like which state has the most diabetics in it." The researcher encouraged the pair to continue this line of exploration, asking, "what do you need to keep working on that?" They responded, "Say like, California's population is, like, 100 people? And like who has diabetes, and like Washington, 58? Something like that. We're not sure [if] that is what the map is used for." We interpret this to suggest that this pair, like the pair of students featured above, were expecting that the map could reflect proportions of people in different states who suffer from diabetes as an extension of the nutritional dataset.

Phase 4: Sustained curricular implications of students' map focus

We find it meaningful that this rich engagement with the map emerged despite our plans, and deepened as a result of both student and teacher actions. Analyzed in the context of researcher, teacher and student dialogue, students' expansive data reasoning had been prompted by Ms. Phillips' reframing of the task in response to student interest in the map in earlier periods. Although our original goal for this day was to support a Third Space between teachers and students, we found it increasingly valuable to envision our broader attention to collaborative curricular design as a part of this emergent Third Space.

To attune to the lessons learned from Day 17, we have made geospatial data visualization a core part of how students engage with datasets and science topics. As part of this map dataset engagement, we support and leverage the practice of locating one's social worlds on maps that are related to or a part of, in different ways and at different scales, the datasets under study. For example, a grounding theme in a climate change unit is for students to think about their own "special places" in the world, and to interview friends and family about their "special places"—including how the landscape, everyday experience, and livability of these places may have been impacted by climate change and pollution. Students then locate these places on the map, creating a personally relevant but geographically distributed framework around which broader examinations of global climate and emissions patterns can be explored. Similarly, we make space for exploratory activities related to data and tools that can provide similar serendipitous moments for student interest to guide the teacher and researchers to more opportunities for learning.

There were also practices we observed in our data that were not leveraged or integrated by teachers and researchers in the moment. Notably, despite our stated commitment to supporting multilingual students, we observed that several students engaged in translanguaging during Day 17, especially as they jointly looked for themselves on the map and told stories about various places or origin or import. However, this practice went unsupported and remained marginalized at the time. Since this time we have significantly altered the way we support translanguaging in subsequent units, explicitly providing fully bilingual (Spanish and English) materials and models of flexible language use. However, our failure to notice and respond to this opportunity in the moment also reveals the degree to which our own and the teachers' research and instructional priorities shape what gets reorganized, and along what dimensions of activity, in the moment of curriculum enactment.

Discussion

We introduced this case as a new way to think of Third Space as a context for collaborative design. In particular, we offer this case as an entry point to think about new ways of thinking about what it means to design for equitable and consequential learning. Our findings reveal a few important considerations that are especially relevant to considering generative collaborative design in the context of formal, STEM-focused settings. First, we noted that shifts in the object of activity led to important rethinking of the use of CODAP as an exploratory tool, the nutrition dataset as the object of study, and of the goals of curriculum as both teachers and students, and the teacher and researcher began to view their work as a shared practice—a practice marked by reciprocal relations of exchange. Second, we found that this example presents a new way of thinking about codesign not as receiving input or feedback either during the conceptualization or the design of an activity, but in the moment of enactment as new paths of exploration are revealed. This is particularly interesting within the context of a formal STEM classroom.

Finally, the case highlights how institutional, research, and teacher priorities can shape what sorts of reorganization is possible. Importantly, we observed the emergence of a Third Space and the reorganization of activity along the dimensions of tool use (the CODAP tool and its embedded maps, text boxes, graphs, and tables); the object of activity (from attending to patterns in data to also considering its connection to personal and social issues, including health topics previously studied in class); and social roles (as the teacher rejected researchers' recommendations in favor of following students' lead). At the same time, other student practices that were aligned with our purported goals and that co-occured with students' map use, such as translanguaging, were not taken up in the moment. This highlights the importance of communicating and revisiting project goals to elevate their priority. It also highlights the importance of reflecting on missing elements of reorganization to find "blind spots" and missed opportunities in design.

Future co-design efforts can learn from this case. Because students will initiate "counterscripts" and other "grammars of the Third Space" alongside and in tension with teacher-centered whole-class discourse (Gutiérrez, 2008), teachers should expect the emergence of such counterscripts and analyze them in real time to the best of our ability. As we saw in our project with student interest in the map, these counterscripts served as productive resources for learning that otherwise might have remained unnoticed and marginalized, but instead were productively leveraged for deeper learning in a collective ZoPED. If teachers and codesigners in other projects commit to actively searching for and uplifting student sensemaking to support a Third Space, they may also see a similarly productive reorganization of learning and see the emergence of another collective ZoPED.

Abstract: Prior research shows that self-explanation promotes understanding by helping learners connect new knowledge with prior knowledge. However, despite ample evidence supporting the effectiveness of self-explanation, an instructional design challenge emerges in how best to scaffold self-explanation. In particular, it is an open challenge to design self-explanation support that simultaneously facilitates performance and learning outcomes. Towards this goal, we designed *anticipatory diagrammatic self-explanation*, a novel form of self-explanation embedded in an Intelligent Tutoring System (ITS). In our ITS, anticipatory diagrammatic self-explanation scaffolds learners by providing visual representations to help learners predict an upcoming strategic step in algebra problem solving. A classroom experiment with 108 middle-school students found that anticipatory diagrammatic self-explanation helped students learn formal algebraic strategies and significantly improve their problem-solving performance. This study contributes to understanding of how self-explanation can be scaffolded to support learning and performance.

Introduction

Self-explanation

Self-explanation is a learning strategy in which learners attempt to make sense of what they learn by generating explanations to themselves (Chi et al.,1989; Rittle-Johnson et al., 2017). A number of studies have provided evidence for the effectiveness of self-explanation across domains (Ainsworth & Loizou, 2003; Bisra et al., 2018). From a cognitive perspective, self-explanation helps learners integrate to-be-learned information with their prior knowledge, leading to deeper understanding of the content (Bisra et al., 2018). For example, in the context of problem solving in mathematics, learners may be asked to provide reasoning for their solved steps in order to deepen their conceptual understanding of the procedures. Although self-explanation activities may take different forms (e.g., explaining worked examples, explaining while solving problems, and explaining text passages), they share the core principle of supporting deeper understanding through connecting new content with existing knowledge.

Scaffolding self-explanation as a challenging design problem

The demonstrated effectiveness of self-explanation does not guarantee that effective self-explanation activities are easily designed. Self-explanation can be a demanding task for learners. It has been reported that scaffolding self-explanation activities facilitates learning (Rittle-Johnson et al., 2017). Prior studies have designed and tested various types of scaffolded self-explanation, such as presenting menu-based, multiple-choice explanations (Aleven & Koedinger, 2002; Berthold et al., 2011; Rau et al., 2015), providing training on self-explanation (Hodds et al., 2014), using visual representations (Ainsworth & Loizou, 2003; Nagashima, Bartel et al., 2020), using contrasting cases (Sidney et al., 2015), and providing feedback on self-explanation (Aleven & Koedinger, 2002).

All of these types of self-explanation support have been shown to be effective. Yet, there are still challenges in how best to design optimal scaffolding support for self-explanation. A first challenge lies in how to design scaffolded self-explanation to promote both conceptual *and* procedural knowledge. Acquiring both conceptual and procedural knowledge is fundamental to learning (Rittle-Johnson & Alibali, 1999); however, studies on scaffolded self-explanation have typically shown it to be effective for enhancing either conceptual knowledge *or* procedural knowledge, but not both (Berthold et al., 2011; Nagashima, Bartel et al., 2020; Rau et al., 2015, but see Aleven & Koedinger, 2002). Rittle-Johnson et al. (2017) explain that this disassociation may be due to the unique characteristics of specific forms of scaffolding. Self-explanation scaffolding designed to focus on one aspect of content may hinder learners' focus on other important aspects. For example, asking students to select a correct conceptual explanation from among a list of similar explanations in a multiple-choice format would encourage learners to focus on conceptual understanding of the content, but it would not give an opportunity for learners to develop their procedural skills (e.g., problem-solving skills).

A second challenge is how to design scaffolded self-explanation that enhances problem-solving performance when combined with, or embedded in, problem-solving activities. Self-explanation can be time-consuming, and because self-explanation requires learners to engage in additional cognitive activities, learners who receive self-explanation support may solve fewer problems in a limited amount of time compared to solving problems without self-explanation support. If scaffolded appropriately during self-explanation, learners' performance on the target task would improve. This would result in *efficient* learning (i.e., learners with self-explanation achieve similar learning gains with fewer problems or less time spent compared to those without self-explanation). Most prior studies of self-explanation do not report measures of the problem-solving performance and efficiency of learning with self-explanation, such as time spent on the task (Bisra et al., 2018; but see Aleven & Koedinger, 2002). In sum, there are persistent design challenges in how to design effective and efficient self-explanation that supports both learning and performance.

Designing evidence-based self-explanation scaffolding

To approach these challenges, we designed self-explanation support for a web-based educational software called an Intelligent Tutoring System (ITS) for algebra problem solving (Long & Aleven, 2014). In our design, self-explanation is *interleaved* with problem solving; learners are asked to *explain* the next strategic problem-solving step in the form of a diagram before doing the same step in symbols (Figures 1-3). They receive feedback from the ITS both on their *explanation* and their step using mathematical symbols. We designed the self-explanation support following several evidence-based principles from cognitive psychology, educational psychology, instructional design, and the learning sciences, which we describe below.

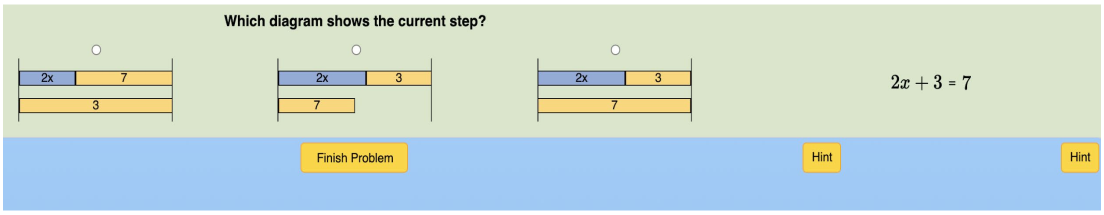

Figure 1. The ITS starts by asking a learner to select a correct diagram for the given equation. The ITS gives correctness feedback on the learner's choice of diagram.

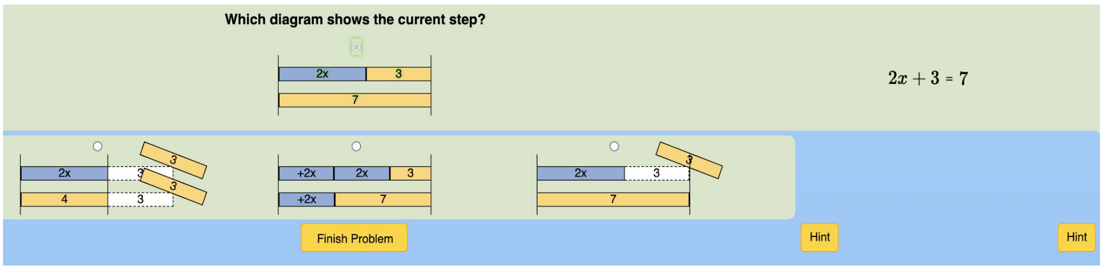

Figure 2. Next, the ITS asks the learner to *explain* (by selecting a diagram) what would be a correct and strategic step to take next. The ITS gives feedback on the choice of diagram.

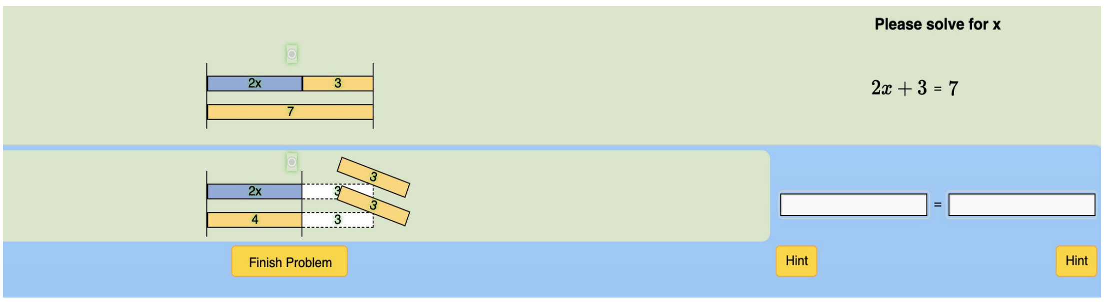

Figure 3. After selecting a correct and strategic step, the learner enters the step in symbols.

Visual representations designed to support students' conceptual understanding

Research has shown that visual representations can support conceptual understanding (Rau, 2017). Visual representations can depict information that is difficult to express through verbal means and can make important information salient. We chose a visual representation called *tape diagrams*, which are commonly used in algebra classrooms in countries such as Japan, Singapore, and the United States (Booth & Koedinger, 2012; Chu et al., 2017; Murata, 2008). Prior studies using tape diagrams in algebra problem solving show that tape diagrams help students gain conceptual understanding and avoid conceptual errors (Chu et al., 2017; Nagashima, Bartel et al., 2020). In particular, our own prior experiment found that diagrammatic self-explanation (in which students, after each equation-solving step, are asked to select, from three options, a diagram that corresponds to the step) helped learners gain conceptual knowledge in algebra (Nagashima, Bartel et al., 2020). In the present study, students are similarly asked to choose tape diagrams as a way to *explain* their steps, following the principle of *anticipatory* self-explanation (Bisra et al., 2018; Renkl, 1997), as explained next.

Anticipatory self-explanation to support understanding of problem-solving strategies

Anticipatory self-explanation is a type of self-explanation in which learners generate inferences about future steps. Previously, Renkl (1997) found that, when prompted to talk aloud while studying worked examples that provided solutions step-by-step, many successful self-explainers predicted solutions in advance. In algebra problem solving, such anticipatory self-explanation, rather than *post-hoc* self-explanation, can potentially support inference generation about strategic problem-solving steps (e.g., "what would be a good next step for the equation, $3x + 2 = 8$?"). If students consider the mathematical symbols as the target representation to learn, engaging in step-level anticipatory self-explanation could help students understand strategic next steps, which would improve both understanding of strategic solution steps and problem-solving performance. On the other hand, post-hoc self-explanation might not be particularly effective for helping students take strategic problem-solving steps.

Contrasting cases that differ on conceptual features and problem-solving strategies

The use of contrasting cases is an established instructional strategy in which learners are presented with contrasting examples that differ in meaningful conceptual aspects (Schwartz et al., 2011). Contrasting cases help learners notice meaningful differences. This instructional strategy is typically used with prompts for self-explanation, to encourage learners to cognitively and constructively engage with the cases (Sidney et al., 2015).

In the self-explanation support used in the current study, three options of tape diagrams are displayed, which differ in one conceptual aspect and one strategy-related aspect. For example, in Figure 2 the tutor displays three diagrams that represent a correct and strategic next step (diagram on the left), an incorrect option (diagram on the right, in which the subtraction is done on only one side of the equation) and an option that is correct but not strategic (diagram in the middle, in which $2x$ was added to both sides, which does not get the learner closer to the solution). This set of options allows learners to distinguish, not only between correct and incorrect steps, but also between *correct and strategic* steps and *correct but not strategic* steps. In problem states in which two correct and strategic steps are available (e.g., subtracting $2x$ from $8x = 2x + 6$ or dividing both sides by 2), the ITS shows those two options and one incorrect option. Engaging with contrasting cases prior to practicing the target problem-solving skill with symbols might be particularly meaningful, because students would be able to follow the selected diagram option when entering the solution step with symbols and thereby learn to use correct and strategic steps.

Present investigation and hypotheses

In the present study, we investigate the effectiveness of scaffolded self-explanation support on learning and performance. We hypothesize that (H1) the anticipatory diagrammatic self-explanation will promote students' conceptual understanding, enhance procedural skills, and help students learn formal algebraic strategies. We also hypothesize that (H2) the anticipatory diagrammatic self-explanation will enhance performance during problem solving in the ITS; students with the support will perform better on learning process measures (e.g., fewer hint requests and fewer incorrect attempts per step) while solving symbolic problem-solving steps, and they will solve a similar number of problems as students who do not receive the scaffolded self-explanation support.

Method

Participants

We conducted an *in vivo* experiment (i.e., a randomized controlled experiment in a real classroom context) at two private schools in the United States. Participants included 55 6th graders and 54 7th graders across nine class sections taught by four teachers. The experiment was conducted in October 2020, when both schools adopted a hybrid teaching mode in which the majority of students ($n = 102$) attended study sessions in-person and the rest of the students attended remotely (n = 7). Teachers reported that they had never focused their instruction on tape diagrams, although they indicated that some students might have seen tape diagrams in their learning materials.

Materials

Intelligent Tutoring System for equation solving

In addition to the anticipatory diagrammatic self-explanation ITS described above, we used a version that did not include tape diagrams (Figure 4) (Long & Aleven, 2014). In this No-Diagram ITS, students learn to solve equations step-by-step, but without diagrammatic self-explanation steps. All other features (e.g., step-level feedback messages and hints) are the same as in the version with tape diagrams. Both ITS versions had four different types of equations, which were chosen in consultation with the teachers (Table 1). We only used equations with positive numbers since tape diagrams were not found useful for representing negative numbers (Nagashima, Yang et al., 2020). Most of the participants in this study, per teachers' report, had seen or practiced Levels 1 and 2 problems, but had not learned Levels 3 and 4 problems.

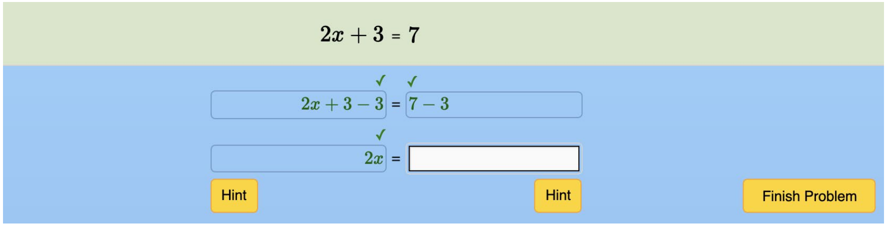

Figure 4. A version of ITS with no diagrammatic self-explanation.

Table 1: Types of equations the tutor contained and the number of problems in the tutor

	Equation type	Example	Number of problems in the ITS
Level 1	$x + a = b$	$x + 3 = 5$	4
Level 2	$ax + b = c$	$2x + 3 = 7$	5
Level 3	$ax + b = cx$	$5x = 3x + 2$	6
Level 4	$ax + b = cx + d$	$5x + 2 = 3x + 8$	13

Test instruments

We developed web-based pretest and posttest assessments to assess students' conceptual and procedural knowledge of basic algebra. The tests contained several items drawn from our previous work (Nagashima, Bartel et al., 2020) as well as new items. The conceptual knowledge items consisted of eight multiple-choice questions and one open-ended question, which assessed a wide range of conceptual knowledge constructs, including like terms, inverse operations, isolating variables, and the concept of keeping both sides of an equation equal. We also included four problem-solving items (e.g., "solve for x: $3x + 2 = 8$"), including two items that were similar to those included in the ITS and two transfer items involving negative numbers. We developed two isomorphic versions of the test that varied only with respect to the specific numbers used in the items; participants received one form as pretest and the other as posttest (with versions counterbalanced across subjects).

Procedure

The study took place during two regular mathematics classes. The classes were virtually connected to the experimenters and remote learners through a video conferencing system. Students were randomly assigned to either the Diagram condition or the No-Diagram condition. In the Diagram condition, students used the ITS with anticipatory diagrammatic self-explanation. In the No-Diagram condition, students used the ITS with no self-explanation support. The only difference between the Diagram and No-Diagram conditions was whether students self-explained their solution steps in the form of tape diagrams or not.

On the first day, all students first worked on the web-based pretest for 15 minutes. Then a teacher or the experimenter showed a 5-minute video describing how to use the ITS and what tape diagrams represent to all students. Next, students practiced equation solving using their randomly-assigned ITS version for approximately 15 minutes. On the second day, students started the class by solving equation problems in the assigned ITS for approximately 15 minutes. After working with the ITS, students took the web-based posttest for 15 minutes. Students were given access to both ITS versions a week after the study.

Results

Pre-post test results

One 6th grader was absent for the second day and excluded from the analysis; therefore, we analyzed data from the remaining 108 students, namely, 54 6th-graders (28 Diagram, 26 No-Diagram) and 54 7th-graders (27 Diagram, 27 No-Diagram). Open-ended items were coded for whether student answers were correct or incorrect by two researchers (*Cohen's kappa* = .91). Table 2 presents raw pretest and posttest performance on conceptual knowledge (CK) and procedural knowledge (PK) items. The maximum scores were 9 and 4, respectively.

Table 2: Means and standard deviations (in parentheses) for CK and PK on the pretest and posttest

	CK (maximum score: 9)		PK (maximum score: 4)	
	Pretest	Posttest	Pretest	Posttest
Diagram	3.53 (1.56)	3.80 (1.94)	1.51 (1.17)	1.73 (1.39)
No-Diagram	3.42 (2.02)	4.01 (2.27)	1.55 (.92)	1.83 (1.57)

We first tested hypothesis H1 (benefits of anticipatory diagrammatic self-explanation with respect to learning *outcomes*). We analyzed the data using hierarchical linear modeling (HLM) because the study was conducted in nine classes taught by four teachers at two schools. According to both AIC and BIC, a two-level model showed the best fit, in which students (level 1) were nested in classes (level 2). The inclusion of teachers (level 3) and schools (level 4) did not improve the model fit. We ran two HLMs with posttest scores on CK and PK as dependent variables, type of ITS assigned as the independent variable, and pretest scores (either CK or PK given the dependent variable) as a covariate. For both CK and PK, there was no significant effect of the Diagram/No-Diagram condition (CK: $t(99.3) = -1.030$, $p = .31$, PK: $t(99.4) = -0.292$, $p = .77$). We also ran two additional HLMs, regressing pretest-posttest gains for CK and PK (dependent variables) on type of ITS. There was a significant gain from pretest to posttest for CK ($t(108) = 2.778$, $p < .01$) but not for PK ($t(106) = 1.153$, $p = .26$), and no significant effect of ITS type. This suggests that students in both ITS conditions improved in conceptual knowledge but not in procedural knowledge.

We then analyzed the strategies that students used to solve the problem-solving items on the pretest and posttest. We adopted a coding scheme by Koedinger et al. (2008), which identified both formal (algebraic) and informal (non-algebraic) ways of solving equations (*Cohen's kappa* = .73; Table 3). We were primarily interested in the Algebra strategy because the goal of the ITS was to help students learn the formal algebraic strategy. We performed the strategy coding independent of the correctness coding used to calculate students' test scores. On the pretest, 11 students in the Diagram condition and 17 students in the No-Diagram condition used the Algebraic strategy on one or more problem-solving items. More students did so on the posttest; 26 students in the Diagram condition and 23 students in the No-Diagram condition used the Algebraic strategy. We used McNemar's test to compare the frequency of use of the Algebra strategy at pretest and posttest for each condition. The increase in frequency was significant ($p < .01$) for students in the Diagram condition but was not significant ($p = .11$) for students in the No-Diagram condition. This pattern also held when we limited the analysis to problems involving negative numbers (transfer problems); there was a pretest-posttest increase of only 1 student in the No-Diagram condition, but 12 students in the Diagram condition ($p < .01$). These findings suggest that, although students who learned with anticipatory diagrammatic self-explanation did not have greater gains on tests of conceptual and procedural knowledge, they were more likely to learn the formal algebraic strategy and to apply it to problems with no diagram support, even for problem types that they did not practice in the ITS (H1 partially supported).

Table 3: Strategies used to solve equations, adapted from Koedinger et al. (2008)

Strategy name	Description	Example answer for $3x + 2 = 8$
Algebra	Student uses algebraic manipulations to find a solution	$3x = 6$ $x = 6/3 = 2$
Unwind	Student works backward using inverse operations to find a solution	$8 - 2 = 6$ $6/3 = 2$
Guess and Check	Student tests potential solutions by substituting different values	$3*2 + 2 = 8$ $6 + 2 = 8$
Other	Student uses other non-algebraic strategies	$3 + 2 = 5$ $8/5 = 1.6$

Answer Only	Student provides an answer without showing any written work	$x = 2$
No Attempt	Student leaves problem blank or explicitly indicates that she/he does not know how to solve the problem	"I don't know"

Log data analysis on students' learning processes

Next, we tested hypothesis H2 (benefits of anticipatory diagrammatic self-explanation with respect to learning *processes*), using log data from the ITS. Specifically, we looked at "learning curves", which plot students' performance within the ITS over time (Rivers et al., 2016). Figure 5 depicts learning curves for the two conditions. The y-axis shows the error rate on steps in tutor problems, averaged across students and skills, and the x-axis shows the sequence of opportunities for practicing each skill. Learning curve analysis assumes that learning occurs when a curve starts with a relatively high initial error rate and gradually goes down as students practice the target skills. The curves are fit to student performance data using the Additive Factors Model (AFM), a specialized form of logistic regression (Rivers et al., 2016). In our study, students practiced a variety of equation-solving skills (e.g., subtracting variable terms). We expected that students who learned with diagrammatic self-explanation support would perform better in the ITS than their peers who did not receive the support (H2). On the symbolic problem-solving steps in the ITS (i.e., excluding the performance on the self-explanation steps, which only occurred in the Diagram condition), students in the Diagram condition had a lower error rate than students in the No-Diagram condition. Figure 5 shows learning curves averaged across all symbolic equation-solving skills students in both conditions practiced. Students in the Diagram condition made fewer errors than those in the No-Diagram condition, especially on the earlier opportunities. Both groups improved as they solved more problems (i.e., both curves show a gradual decline). After much practice, the No Diagram condition eventually lowered their error rate to the same level as the Diagram condition.

In parallel to the trend observed in the learning curves, we found that, when restricting the analysis to symbolic steps only (i.e., excluding diagrammatic self-explanation steps), students who received the self-explanation support trended toward using fewer hints ($t(89.52) = -1.812$, $p = .07$) and spent significantly less time on each symbolic problem-solving step ($t(99.51) = -2.238$, $p = .03$) than students who did not receive the self-explanation support (Table 4). The average number of problems solved in the ITS during the (fixed amount of) available time did not differ significantly across conditions, ($t(99.30) = -0.528$, $p = .60$) (Table 4).

In summary, the students in both conditions practiced a similar number of problems in the ITS in a similar amount of time overall, and the anticipatory diagrammatic self-explanation helped students spend less time and ask for fewer hints on symbolic steps (H2 partially supported). In addition, the learning curves indicate that students in both conditions learned equation-solving skills eventually, but the students in the Diagram condition learned them faster and had a smoother experience, with fewer errors.

Table 4: Average number of problems solved, number of incorrect attempts, number of hint requests, and average time spent on symbolic steps in the ITS (standard deviation).

	Average number of problems solved	Average number of hints requested per step	Average time spent per step
Diagram	15.40 (9.02)	0.68 (0.96)	15.99 (9.91)
No-Diagram	16.17 (11.16)	1.02 (1.38)	20.27 (13.95)

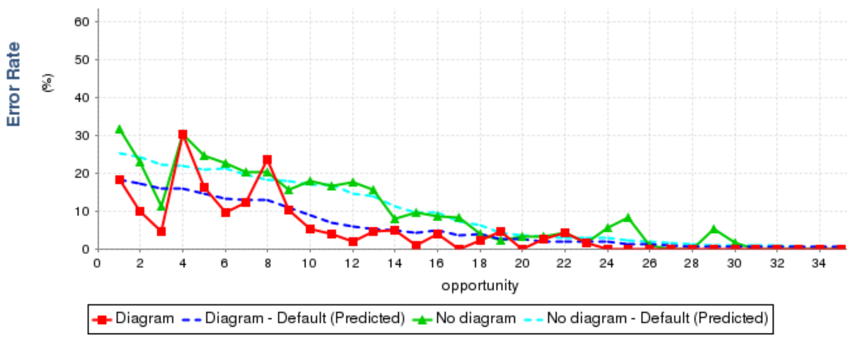

Figure 5. Learning curves for the Diagram condition (red) and the No-Diagram condition (green) averaged across the skills students practiced during the symbolic problem-solving steps. Dark and light blue lines show predicted curves based on the AFM (dark blue: Diagram condition, light blue: No-Diagram condition).

Discussion and Conclusion

Self-explanation has been shown to support student learning in various domains, but it is not easy to design appropriately-scaffolded self-explanation activities. Our study investigated the effectiveness of anticipatory diagrammatic self-explanation as a proposed approach to enhancing both learning and performance. We found that anticipatory diagrammatic self-explanation embedded in an Intelligent Tutoring System (ITS) helped students learn to apply a formal, algebraic problem-solving strategy to problems outside the ITS and to transfer problems involving negative numbers (H1). Anticipatory diagrammatic self-explanation also supported student performance within the ITS, measured by lower learning curves, less frequent use of hints, and less time spent on each symbolic equation-solving step (H2). Anticipatory self-explanation did not lead to differences in posttest scores, contrary to H1, but it helped students learn more efficiently; students learned the formal algebraic strategy while solving a similar number of problems with less time and fewer errors and hint requests, and they achieved similar gains on conceptual knowledge (H2).

We attribute these findings to the design and learning principles used in supporting anticipatory diagrammatic self-explanation. Specifically, we reason that the process of selecting the next correct-and-strategic problem-solving step, depicted diagrammatically, helped students perform better and faster on the corresponding step with symbols. On steps with symbols, students had a diagrammatic representation of the step available to them on the screen. They could refer to this representation as they sought to express the step using mathematical symbols. Engaging in this cognitive process may have helped students understand step-level formal strategies in a visual form (e.g., visually seeing that constant terms are taken out from both sides of an equation). Comparing and contrasting the different tape diagrams may have supported students in selecting steps that were both correct and strategic, and it may have helped them avoid using informal strategies, such as guessing. It may be, as well, that the better performance resulting from the anticipatory diagrams gave students a bit more confidence to take on the challenge of moving towards formal algebra.

An intriguing question is why the ITS with anticipatory diagrammatic self-explanation did not lead to greater gains in conceptual and procedural knowledge than the ITS with no diagram support. Regarding procedural knowledge, students did not make gains from pretest to posttest in either condition. Further, there was no difference in solving equations correctly between the conditions at post-test, even though students with diagrams exhibited greater use of formal problem-solving strategies. It is possible that students in the Diagram condition might need more practice in *correctly* applying the formal strategy they acquired in the ITS without the help of diagrams. In other words, it seems that students in the Diagram condition developed further towards formal use of algebra than their counterparts in the No-Diagram condition, but not yet to the extent that the use of the more challenging formal strategies paid off in terms of improved correctness. Regarding conceptual knowledge, it might be that the anticipatory use of diagrams in the ITS focused students primarily on *strategic* issues, as the diagrams were used in planning problem-solving steps. It may be that students need to engage in "principle-based explanation" (Renkl, 1997) to facilitate acquisition of conceptual knowledge (e.g., verbally explaining *why* the selected diagram is correct and strategic). It might also be that students with varying levels of prior knowledge benefit from diagrammatic self-explanation differently (Booth & Koedinger, 2012). Future studies should examine the effects of anticipatory diagrammatic self-explanation with students having varying degrees of prior knowledge and experience in algebra.

Our study has several limitations. First, the study was conducted with one specific type of diagrams, tape diagrams, and it focused on one specific task domain, equation solving in algebra. To understand how the results could generalize across domains and types of visual representations, more research is needed to examine the effects of anticipatory diagrammatic self-explanations. Also, it is possible that students were not very motivated to work on the posttest, especially given that the study was conducted remotely during the COVID-19 pandemic. This may have contributed to the absence of pretest-posttest gains in procedural knowledge, even though the learning curves suggest that learning occurred.

In summary, we designed a novel self-explanation scaffolding support for students in middle-school algebra, namely, anticipatory diagrammatic self-explanation. We investigated the effectiveness of this support embedded in an Intelligent Tutoring System, in a classroom study. We found that anticipatory diagrammatic self-explanation helped students learn formal algebraic strategies and perform better on problem solving, while making similar conceptual gains as students who did not receive the support. Our study contributes to the theoretical and practical understanding of how visual representations, contrasting cases, and anticipatory self-explanation can be integrated into scaffolding support that helps students learn and perform effectively and efficiently.

Designing a Workshop to Support Teacher Customization of Curricula

allison_bradford@berkeley.edu, sbichler@berkeley.edu, mclinn@berkeley.edu
Graduate School of Education, University of California, Berkeley

Abstract: We report on design-based research to refine a professional development workshop that supports teachers to customize online curricula. We iteratively design representations to make the knowledge integration pedagogy of the curricula visible. We study ways to make the work of students using the curricula actionable for participating teachers. We analyze participants' trajectories across the three iterations of the workshop. Initially, when participants realized they could customize the online curriculum, they developed feelings of ownership. Then, as participants deepened their understanding of the pedagogy, they began to use it to evaluate their own instruction. The trajectory culminated in participants connecting the pedagogy to student work from their own classroom. This led to a shift from focusing on remedies for misconceptions to seeking opportunities for building on students' nascent ideas when customizing. The workshop refinements empowered teachers to mobilize the pedagogy to interpret their students' work to inform their customization decisions.

Keywords: professional development, design-based research, technology-enhanced learning

Major issues and objective

When teachers implement new materials, they often customize instruction to align with existing classroom practice, particularly when the materials are designed based on a different pedagogical framework (Matuk, et al., 2016; Remillard, 2000; Schneider, et al. 2005). We explore the design and impact of a professional development workshop that takes advantage of technology to make curriculum designers' pedagogical design intentions visible alongside the curriculum and to enable teachers to use student work to plan customizations. We investigate how these supports enable teachers to appreciate the instructional goals of the materials and make connections to their students' ideas. The workshop supported teachers to customize instruction while attending to contextual constraints such as available classroom time and new standards. Furthermore, we designed technologies to help teachers with limited time to efficiently gather data to inform their customizations. Teachers often lack time to gather and respond to data they perceive as relevant (Kerr, et al., 2006) leading to mixed outcomes for students (e.g., Bismack et al, 2015; Davis, et al., 2017; McNeil, 2009). When teachers anchor their customizations in evidence, particularly from student work, they are able to make better customizations (Gerard, et al. 2010).

The workshop design draws on the notion of educative materials (e.g., Davis and Krajcik, 2005) to support the development of teachers' pedagogical design capacity (Brown, 2009; Brown & Edelson, 2003). To support teachers' pedagogical design capacity, we used a visual representation of the curriculum to make visible the pedagogical intention behind each activity in the units visible. The representation supports teachers to consider pedagogical implications as they planned revisions customizations to the curriculum. Because attending to student work and ideas has been shown to lead to more impactful instruction (e.g., Carpenter, et al., 1989; Coffey, et al., 2011; Fennema, et al., 1996), the workshop design guides teachers to examine student work collected in their own classrooms before they plan and implement their customizations. Specifically, the workshop design engages teachers in goal setting, analyzing student work to identify possible revisions, and designing customizations to the content and assessments embedded within the curriculum based on the analysis. The teachers then implement the customized units and return for a subsequent workshop. We refined the workshop based on the researcher and teacher reflections. We describe the three design iterations and the impact design changes had on teachers' use of student work and pedagogy. Our research questions are:

- How do improvements in the representation of the pedagogical framework underlying the curriculum facilitate teachers' consideration of pedagogy while customizing?
- How do refinements in providing access to student work support teachers to analyze that work as they customize the curriculum and their instructional approach?

Workshop design and iterations

Knowledge Integration framework

The Knowledge Integration (KI) Pedagogical Framework (Linn & Eylon, 2011) informs both the design of the interactive online science units and the workshop for teachers. The KI framework builds on constructivist perspectives (Inhelder & Piaget, 1958) that acknowledge that learners bring multiple prior ideas about scientific phenomena into the classroom and engages students in exploring their own and new ideas as they develop coherent understanding. In the context of the online science units, each lesson in the unit follows the research-based KI processes (Linn & Eylon, 2011). Units might start with activities where students make predictions about phenomena to *elicit* their prior knowledge. Next students might *discover* new ideas by engaging with interactive scientific models and discussing ideas with peers. Having accumulated a repertoire of ideas, students then *distinguish* among their ideas by testing their hypotheses in new scenarios or sorting which ideas are relevant under certain circumstances. Finally, students *reflect* on how their new ideas fit with their initial ideas.

We designed the professional development workshops following the same pedagogy as the interactive online science units and implemented the workshops with an online unit using the same technology as the online science units. By using the same technologies and pedagogy, the workshop modeled the instructional approach that it also advocated. Applying the KI framework to the workshop design, we first elicit teachers' ideas about their goals for student learning and what they hope to achieve using the unit. Next, we support the teachers to discover new ideas about how the unit is functioning in their classrooms through analysis of student work from the unit they are customizing. Teachers analyze student written explanations from key assessments embedded within the unit in conjunction with their recollections of student learning while teaching to determine areas of the unit that need to be strengthened in order for students to achieve mastery of aligned standards. This spurs the teachers to think of ways to customize the unit to strengthen student learning. Next, we introduce the idea of KI pedagogy as a means to distinguish which customizations to make and to consider where new activities fit with existing activities. By considering the pedagogical intention of the activities already in the unit, teachers can distinguish how best to integrate new activities. Finally, teachers teach the customized version of the unit and reflect on the efficacy of their customizations.

Making the Knowledge Integration pedagogy visible

At the workshop, we made the KI pedagogy in the unit visible. We made the KI pedagogy underlying the curriculum design visible in two ways. First, we supported teachers to connect KI processes such as distinguishing ideas to examples of activities in their existing practice. This deepened understanding of the pedagogy and of the characteristics of their own practice. Second, we used a visual representation of the KI processes underlying each activity in each unit to illustrate the interactions across processes (Figure 1). Lastly, we designed the workshop following the same pedagogical framework, KI, in order to model the instructional approach for teachers.

<u>Connecting KI to teacher practice</u>

In the first workshop we introduced the KI processes and some examples of activities from the units that engaged each process. Then, teachers brainstormed examples of their own activities and classroom practices, recorded them on post-it notes and sorted the examples by KI process. For example, teachers sorted their use of Know-Want to Know-Learned (KWL) charts as eliciting students' ideas and their use of Venn diagram graphic organizers as helping students distinguish among their ideas. In the second workshop, researchers similarly demonstrated examples from the units, and illustrated how each lesson of the unit engages students in each of the KI processes. Then teachers, many of whom were now familiar with the KI processes from the first workshop, met in small groups to discuss how their initial customization ideas aligned with the KI processes. In the third workshop, we supported the teachers to connect the KI pedagogy to their classroom assessment. We generated a sample of their students' responses from the log files and annotated the responses by their students' degree of integrated understanding.

<u>Visual representation of KI in the unit</u>

In the first workshop we used notecards to represent the lessons in each unit and color-coded post-it notes to represent the individual KI processes in each activity in the unit. Teachers found the notecards and post-its useful for understanding the design of the units and inserting their own activities. However, they were difficult to use during collaboration and hard to share. In the second workshop, we transitioned to using online technology to represent the units. We created an online version of the notecard and post-it approach using Google slides. We initially created one slide for each lesson, with colored boxes representing the processes in the activities. Teachers found this approach frustrating because they could not easily add their own activities and the activities were organized only by KI process and not sequential order.

(a) (b) (c)

Figure 1. Progression of the planning tool: (a) Year 1, (b) Year 2 and (c) Year 3. The color of each post-it/text box/slide represents the KI process engaged by the activity written on it: Pink for eliciting ideas, orange for discovering ideas, green for distinguishing ideas, and blue for reflecting on ideas.

The third representation improved the use of Google slides. Each activity in the lesson was assigned a separate slide, making it easy to rearrange the sequence and to add new activities. As shown in the figure, a black slide was used to indicate a new lesson. Each step in the lesson was then represented with a slide color-coded for the KI process it represented. This enabled participants to appreciate the overall structure of the unit as well as the role of each activity. Teachers could easily add new activities from color-coded template slides, prompting them to consider the KI process engaged by the activity they intended to add. This representation enabled greater collaboration among teachers customizing the same unit. It also gave teachers the ability to move between focusing on the details of one activity and focusing on the composition of the unit as a whole.

Making student work accessible

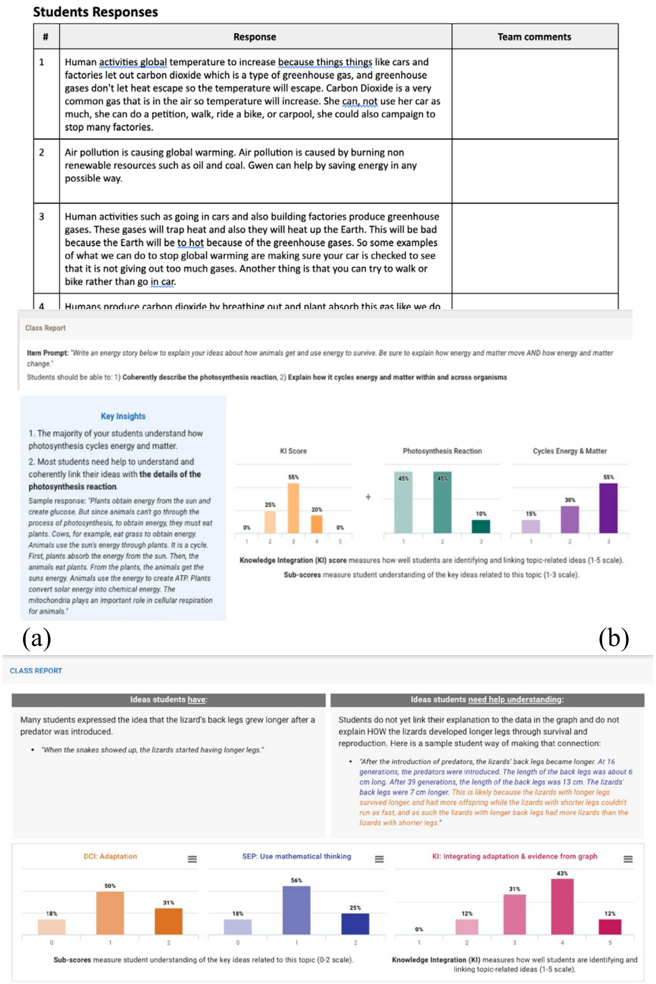
We engaged teachers in analysis of student work to help inform the customization decisions they make and refined our design for accessing student work across the three workshops (Figure 2). In the first workshop, teachers were grouped by unit. Each group received a spreadsheet with a random selection of student responses to an open explanation question in the unit. For each unit, we selected an open explanation question that assessed one of the standards addressed by the unit and came at a point after students had engaged in a full KI cycle around that standard. Teachers found the examples informative for discussing the unit and student understanding with their peers. They were reluctant to use these examples when customizing their own instruction, preferring to rely on their classroom observations (e.g. Kerr, et al., 2006). This motivated a redesign to connect teachers to their own students' work. In the second workshop, we developed learning analytics that summarized student work on an open explanation question in the unit and created personalized summaries for each teacher, based on the responses of their students. Teachers found the summary useful for explaining their students' progress and highlighting specific ideas that students needed more support to develop. They continued to also rely on their own recollections. In the third workshop, we enabled teachers to examine their student work immediately during instruction as well as during the workshop. During instruction, we used the learning analytics to generate the summary of student work as the teacher implemented the unit. Some teachers began identifying ways to build on their students' ideas when they got the summary during instruction and further developed their ideas during the workshop. At the workshop, we also engaged teachers in sorting a sample of their own students' responses by the level of KI to deepen their understanding. After they scored the responses, we had teachers compare their sorting with researchers' annotated comments on their students' responses. Thus, across the three workshops, we increased access to the specific student work generated in each teachers' classroom. We also helped teachers contextualize their student work by analyzing it at the same time as they were teaching the unit.

Methods

To answer our research questions, we analyzed teacher reflections across the three workshops held over three years. We connect themes from their reflections to the design iterations. We examine how teachers take advantage of their students' work and connect it to the KI pedagogy to strengthen evidence-based instruction. We had to omit analysis of a third aspect of the workshops, authoring technologies, due to space limitations. A subsequent paper will describe our refinements of the authoring technologies for teachers and the teacher reflections on it.

Participants

Seventeen teachers attended the first workshop, 19 teachers attended the second workshop, and 23 attended the third workshop. Only teachers who attended at least two of the workshops were included for analysis: twenty-five teachers representing 10 schools participated in at least two of the customization workshops. 56% of teachers were present during all three workshops.



(c)

Figure 2. Representation of students work to guide teacher customization in (a) year 1, (b) year 2 and (c) year 3.

Data sources and analytic procedure

Our data comes from teacher written reflections and researcher field notes from each of the three workshops, taking place in June of three consecutive years. At the end of each workshop teachers were asked to write reflections on their experience of the customization process. The online unit guiding the workshop logged teachers' responses to the reflection questions. Teacher responses to the following questions were used in our analyses:

- What are some things you learned or have taken away from engaging in this customization process and sharing with other teachers?
- Was this customization process and reflecting on the KI cycle helpful for you in thinking about how to achieve your NGSS and other curricular goals?
- Do you think you could use this process again to customize another unit you'd like to run?
- Please share any other reflections of feedback you have from the workshop

Teacher responses to all four questions in each year were combined to represent each teacher's reflection for that year. We began coding with three a priori categories reflecting our research questions and design focus on making pedagogy visible and using student work: *Value of KI Pedagogy,* which were statements about the affordances of considering KI during customization; *Use of Student Work*, which were statements about the utility of student work for customization; and *Value of Technology,* which were statements about engaging with the technology to author their customizations in the online units (omitted for this paper). We used inductive coding (Thomas, 2006) to determine themes within each of these categories to uncover trends in how teachers' reflections within the categories evolved over time. The themes represent the most common ideas teachers expressed in each category of reflection. The themes for each category can be found in Table 1. While analyzing the reflections, we noticed teachers expressing a sense of ownership of the curriculum, so we added *Sense of Ownership* as a category in our coding scheme. Changes in the way themes were represented and discussed at each workshop illustrate the ways in which the refinement of the workshop activities have shaped the teachers' experiences of and approach to customization.

Table 1: Coding scheme and emergent themes for teacher reflections on the workshops

Sense of Ownership	**Value of KI Pedagogy**	**Use of Student Work**	**Value of Technology**
Customization is possible	KI clarifies unit learning objective	Identify misconceptions	Newly aware of tool
Able to meet own goals	KI provides insight into unit design	Identify areas where students struggle	Need individual support to use tools
Able to meet student needs	KI informs customization decisions	Find student ideas to build on	Time consuming to use the tools
Opportunity to integrate resources	KI supports reflection on own practice	Customize to address student needs	Tools make customization accessible

Results and discussion

Teacher trajectory across three years

As we refined the workshop design, the focus of the teachers' reflections shifted (Figure 3). In the first year of the workshop, the most prominent category of teacher reflection was a newfound sense of ownership reflected in the possibility of engaging in customization. In year two, the focus shifted to the use of student work, which aligns with the redesign that provided teachers with student work from their own classroom. Finally, in year three, the focus shifted to the usability of the customization technology, the details of which are beyond the scope of this paper. We analyze the themes of workshop reflections within each category across the three years to connect workshop design features to the customization focus.

Sense of ownership

Ownership emerged as a focus of teacher reflections at the first workshop. The teachers were excited to realize that they could customize the online units. When expressing their sense of ownership after the first workshop, 43% of the 17 teachers present at that workshop wrote that the customization process had enabled them to envision a way to integrate the rest of their successful classroom activities into the online curriculum unit. For example, one teacher wrote that the customization process was "A bit overwhelming also, but very helpful to really make it part of the curriculum, intertwined with the actual curriculum, instead of using the WISE projects as separate from the curriculum." Another 33% expressed that engaging in the customization process enabled them to meet their own goals. One teacher wrote, "Yes, this process made it realistic to reach our curricular goals. I liked reflecting on what in the project is addressing what we want and thinking of ways to add offline [activities]." By the second and third years, there were fewer direct mentions of ownership. This decrease most likely reflects the teachers experiences in the preceding workshops. It became less of a novelty to customize online materials.

Value of KI pedagogy

Over the course of the three workshops, teachers shifted the way they spoke about the relevance of KI for their customization process. Knowledge integration was explicitly mentioned the most during the first year of the workshop. This reflects the amount of workshop time dedicated to developing an understanding of the pedagogical framework and the success of the activity where teachers connected the processes to their existing practice. During the first year, nine teachers mentioned insights from knowledge integration in their reflections. Teachers expressed a variety of insights afforded by the activities to make knowledge integration visible. Thirty percent of teachers described KI as useful for clarifying the learning objectives associated with each unit. Another 30% said the KI framework provided insight into the design intentions of the unit. Thirty percent also described KI as useful for deciding where and how to make customizations.

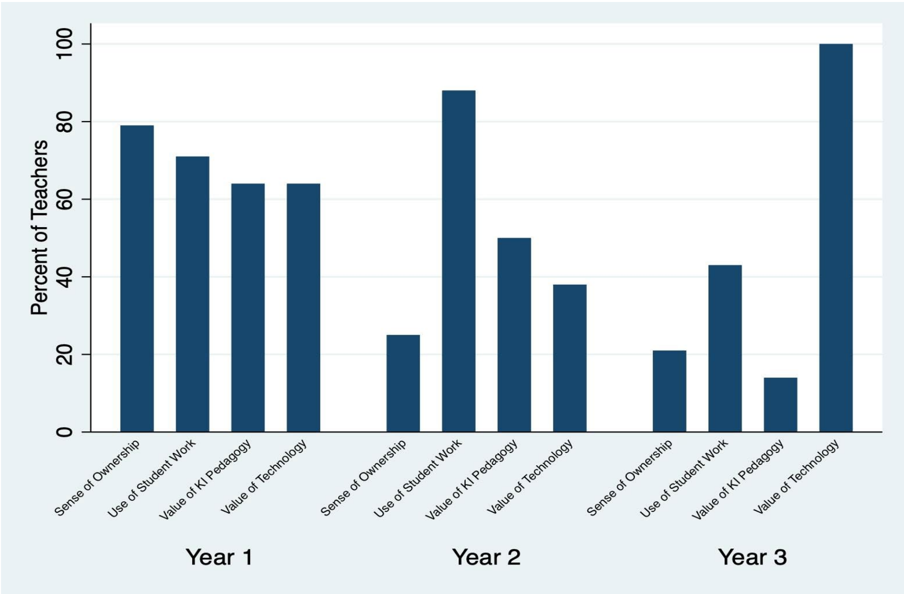


Figure 3. Percent of teachers in attendance during each workshop with reflections in each category

In the second and third years of the workshop, fewer teachers mentioned KI directly, consistent with their increased familiarity with KI and how it informs the units. Furthermore, evidence emerged that teachers had internalized the framework into their goal setting processes since half of the mentions of KI during the second year and all of the mentions during the third year consisted of teachers reflecting on how they implemented KI processes in their own practice. For example, one teacher in the second year wrote "I feel my teaching practice is strong in terms of eliciting ideas, good in terms of adding ideas, and fair in terms of reflecting. I would really like to work on the distinguishing part of the cycle" and another said, "I appreciate time to reflect on my practice and how to be more effective. Rarely do you get a chance during the year to think so deeply about the exact steps of how students connect new information to what they already know."

Thus, the workshop activities supported teachers to reflect on how their own pedagogy interacts with the pedagogy of the units and consider how to improve the units to facilitate student knowledge integration. As teachers considered the KI process of the activities in the units and the activities they were adding, they were supported to reflect on the types of thinking they were asking students to do in their own activities. Prior research shows that teachers typically neglect providing students with opportunities to distinguish among their ideas (Wiley, et al. 2019). By increasing teacher awareness of how their own classroom practices can engage each of the KI processes and supporting teachers to visualize the pedagogical design intention for each activity in the unit, the teachers were better able to evaluate their own practice using the pedagogy. As one researcher overheard during a workshop, a group of teachers exclaimed "We need more green [color of distinguishing activities]!" when evaluating their unit customizations.

Teacher use of student work

Across the three workshops, we refined the activities to guide teacher engagement with student work, increasing access to the specific student work generated in each teacher's own classroom. Teachers shifted how they discussed the relevance and utility of student work for informing their customizations as the workshops progressed. These shifts corresponded with the changes in how we engaged teachers with student work during the workshop. While only one teacher mentioned the use of student work during the first workshop, student work was the most prominent category during the second workshop. This prominence corresponds with our change to showing teachers student work from their own students and introducing learning analytics to provide each teacher with a summary of the ideas in their class. In year two, 55% of teachers found the summaries of student work to be helpful for identifying areas where students were struggling or for identifying misconceptions. This is notable given the open-ended nature of the reflection questions and teachers' specific focus on understanding their students' struggles. One teacher reflected, "Students are struggling to incorporate evidence from models in their explanations." A smaller percentage of teachers (22% each) mentioned in their reflections that analyzing student work was useful for identifying productive student ideas to build on or expressed a direct connection between the ideas in their students' work and their plans for how to customize.

By year three, we were excited to note, teachers' reflections shifted away from identifying incorrect ideas towards using student work to find productive ideas to build on to help students develop more integrated perspectives. The majority of teachers' reflections on student work (86%) expressed a connection between the ideas they saw and the customizations they were planning. The remaining 14% said they found ideas to build on. For example, one teacher wrote, "I love the reflective time and the strategies you teach me to become a wiser user of my student responses/data. I also love the ways you present for thinking about teaching to the needs of my students. I think being able to customize the units to address my preconceptions in student knowledge integration and/or ways of teaching will empower my students to become stronger explainers and reasoners." Another teacher reflected, "due to the sorting activity, I was able to recognize the gaps in student achievement, which spurred me to create scaffolds and re-plan steps for the unit." This shift towards viewing student ideas as productive was more pronounced as the teachers had the opportunity to review their class summary during instruction and to use it for in-the-moment teaching customizations. When they saw it again during the workshop, they were able to reflect on their customization goals. This reaction is consistent with the multiple opportunities to reflect on the same student work. It also aligns with the opportunity to use the class summary during instruction to incorporate the classroom context as teachers got started on building on students' ideas.

Conclusions

We iteratively designed a professional development workshop intended to support customization by making the pedagogy behind our curriculum visible and engaging teachers in analysis of their students' work. We found that the activities designed to make KI visible were initially successful and, as they were improved, became more useful to the teachers. The representation in the first workshop made the instructional goals of each unit explicit and enabled teachers to articulate the connections to their own goals. The move to Google slides and the improvements in the representation provided a more robust view of the KI pedagogy, supported multiple perspectives on the unit, and increased opportunities for teachers to collaborate on customizations. Furthermore, refining the representation of the pedagogy strengthened teachers' ability to integrate their own activities into the unit and led to increased sophistication of the reflections on their own pedagogy as they customized the units

Our methods for making student work accessible increased the likelihood that teachers considered student work as evidence to inform their customizations. This was especially true if the student work was from their own classroom and was directly related to their interactions with students while teaching. In addition, teachers reported that access to the class summary during instruction enabled them to build on their students' ideas. Further, the combination of the class summary and examples of their students' responses provided teachers with a coherent picture of their students' needs and shifted them away from a deficit view of students' ideas as misconceptions or wrong to a KI view of the value of building on student ideas to encourage coherent understanding.

These results illustrate the challenges and value of careful design of teacher workshops. They show that making the pedagogy visible when engaging teachers in customizing curricula has the potential to extend beyond the unit being customized. Teachers reported using the KI pedagogy in their own planning and to connect their offline activities to the online curriculum. These results show the benefit of making student work accessible to help teachers incorporate all their students' ideas rather than only those they recollect at the workshop. The results support viewing the customization process as a trajectory. It starts with ensuring that teachers feel ownership of the customization process. It continues by deepening understanding of the pedagogy behind the instructional design so that the participants integrate it into their own pedagogy. It culminates in connecting the pedagogy to the learning activities of the students. In this case, illustrated by a shift from a focus on addressing misconceptions to a focus on building on the nascent ideas developed by the learners.

Abstract: This study presents a two-year design trajectory of knowledge building and examines the process of how students' epistemic understanding of knowledge building promoted knowledge advancement under the mediation of their engagement on Knowledge Forum, a computer-supported environment. Four iterative studies on the same cohort (*n* =211) from four large Grade-Four classes in China were conducted based on increasing complex knowledge-building designs over two years. Quantitative results obtained from the semantic network analysis of word networks show collective knowledge advancement over time. Qualitative analyses of interviews and questionnaires reveal the developmental trajectory of students' epistemic understanding started from idea-sharing to theory building, collective cognitive responsibility, and finally to progressive knowledge building. As indicated by further path analysis, students' epistemic understanding of knowledge building predicted their Knowledge Forum interaction and depth of Knowledge Forum discourse, which in turn exerted influences on collective knowledge advancement and individual scientific understanding. This study sheds light on the design trajectory of knowledge building to promote epistemic changes and collective knowledge advancement.

Introduction

Recent science education reforms have emphasized the need to engage students in authentic, real-world scientific practices (NGSS Lead States, 2013). Despite the great interest in this field, such engagement is often superficial and limited to fixed and pre-designed activities (Chinn & Malhotra, 2002). Thus, designing an environment that engages students in authentic scientific practices and promotes collective knowledge advancement becomes a major challenge.

In the learning sciences, the focus has long been put on the creation of authentic environments that mirror the practices of specific disciplines (Danish & Gresalfi, 2018). *Knowledge Building*, a major research theme in the learning sciences, relies on the creation of scientific communities (Bereiter et al., 1997). It aims to transform education by introducing the concept of knowledge-building communities (Scardamalia & Bereiter, 2014). Specifically, members of a knowledge-building community work together to foster collective knowledge advancement (Scardamalia, 2002). An online platform Knowledge Forum was developed to support such creative communities' work, which allows students to post problems, co-construct explanations, and conduct sustained inquiries for collective knowledge advancement. The community created by knowledge building plays a vital role in meeting the need for knowledge creation and education innovation. This is particularly important with regard to science education when authentic scientific practices are emphasized. However, most of the knowledge-building studies in the literature lasted a few months or even weeks, while students' engagement in knowledge building has not been investigated over a long time, even though the sustained practice is an important step to examine knowledge building. Thus, two considerations were inspired: (1) how to sustain a long-term development of knowledge-building communities to deploy students' high-level epistemic agency in Knowledge Forum engagement; (2) how to engage students in the kind of knowledge building carried out by scientists, who progressively extend existing knowledge.

As pointed out by Bereiter et al. (2019), the high-level epistemic agency requires students to view their work from a broader perspective, which can be achieved through students' meta-knowledge of knowledge building. Just as knowledge about knowledge (e.g., the nature of science) is necessary for scientific practice, knowledge about knowledge building lays a foundation for students to achieve collective knowledge advancement. Bereiter et al. (2019) discussed the importance of discourse as both an epistemic object of inquiry and a form of explicit knowledge on knowledge building. Several studies have explored how students gain meta-knowledge from knowledge-building discourse (Chan et al., 2019; Tong et al., 2018) and found that students with better insights into knowledge building had a deeper scientific understanding, while those with a deeper understanding of knowledge-building principles had deeper Knowledge Forum engagement.

Accordingly, this study developed a design trajectory and investigated how knowledge building of the same cohort progressed over the two years, focusing on their epistemic understanding of knowledge building.

Specifically, whether and to what extent students made collective knowledge advancement across studies, how their epistemic understanding changed over time, as well as what was the interplay among students' epistemic understanding, Knowledge Forum engagement, collective knowledge advancement, and individual scientific understanding were explored. The research questions are: (1) Did students improve on collective knowledge advancement over time with progressive designs? (2) What characterized students' epistemic understanding of knowledge building, and what was the developmental trajectory of their epistemic understanding across studies? (3) What characterized students' engagement on Knowledge Forum, and what was the interplay among their epistemic understanding, Knowledge Forum engagement, and knowledge advancement?

Methods

Participants

A total of 211 students from four Grade Four (initially) classes participated in this research: Class A (n = 54), Class B (n = 53), Class C (n = 51), and Class D (n = 53). They had no experience of online discussion before the first study. The first author also took on the role of the teacher in the study.

Design trajectory of knowledge building

Four iterative studies were conducted following increasing complex knowledge-building designs over two years. After establishing a basic knowledge-building culture by using Knowledge Forum (KF) (Study 1), the meta-discourse aspect was developed for productive KF discourse (Study 2), followed by the use of *Idea-Friend Maps* (IFM, external representations of a learning analytics tool present data and evidence exported from KF) for collective cognitive responsibility (Study 3). Finally, the refined IFM design supported students along their co-designed collective journey for progressive knowledge building (Study 4). From Study 2, experimental and comparison conditions were included to examine the effects of the knowledge-building designs. Figure 1 depicts the progressive design of KF views combined with the design trajectory of knowledge-building across studies. Figure 2 shows the original and refined IFM used in Studies 3 and 4. Details of the role of IFM designs in scaffolding knowledge building have been reported in Feng et al. (2020).

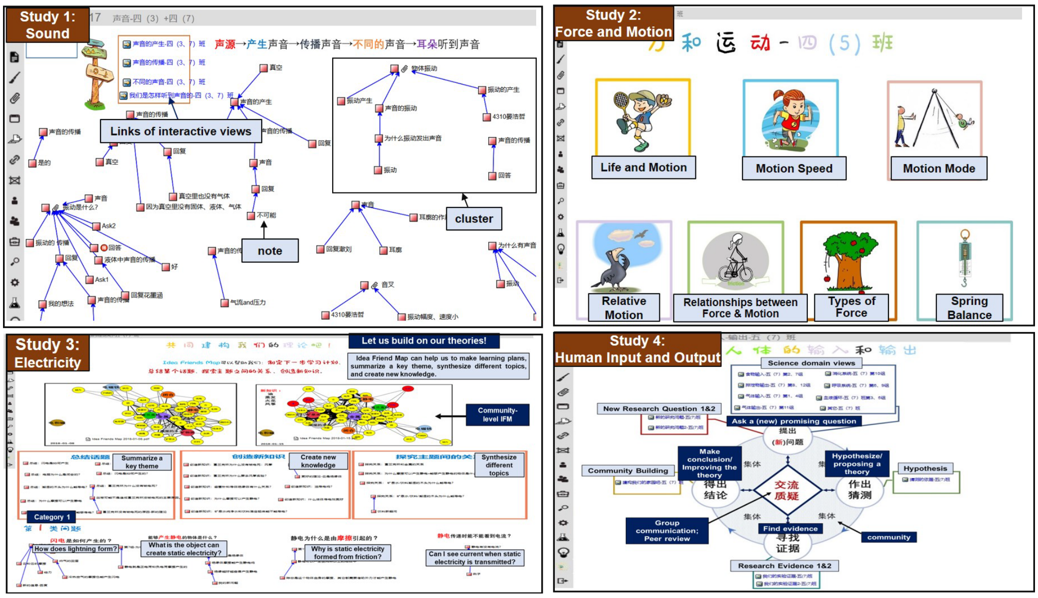

Figure 1. Progressive design of KF views across studies

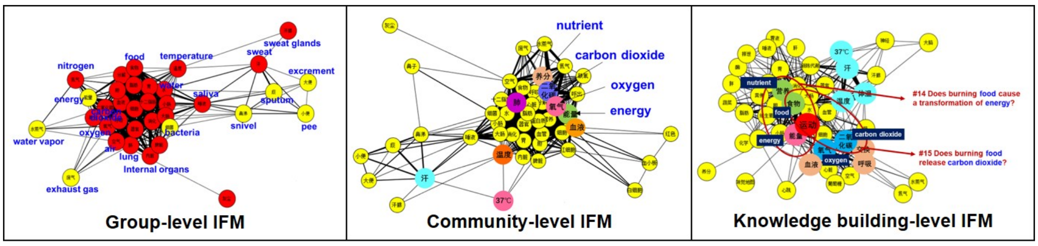

Figure 2. Original IFM: group and community-level IFM. Refined IFM: all three levels of IFM

Study 1 (November 2016 – January 2017)
This study aimed to implement knowledge building as an initial attempt in four classes in China. Students learned *Sound* in each class received the same pedagogy, which encouraged idea-sharing and idea improvement.

Study 2 (April 2017 – June 2017)
The insights gained from Study 1 informed this study, which was aimed at promoting knowledge-building discourse through meta-discourse when studying *Force and Motion*. A face-to-face whole classroom meta-discourse of knowledge-building was first designed as an intervention and focused on theory building and collective cognitive responsibility. A face-to-face offline group meta-discourse was also designed to provide opportunities for students to practice theory building and collective cognitive responsibility. The experimental classes (Classes A and C) received both designs, whereas the comparison classes (Classes B and D) only took part in the whole-class meta-discourse.

Study 3 (November 2017 – January 2018)
Based on the first two studies' findings, this study expected to promote students' collective cognitive responsibility when they were learning about *Electricity*. Students worked like scientists as a community to pursue different but related ideas and conceptualize the community's current state and future direction. Two experimental factors were included. Factor 1 is the IFM (Figure 2), which provides external representations using the learning analytics tool KBDeX (Oshima et al., 2012). Factor 2 refers to a community view (Figure 1) created on KF in the final phase to help conceptualize collective ideas and promote theory building (Zhang et al., 2009). A 2 (*IFM* vs. no *IFM*) × 2 (*Community view* vs. no *Community view*) factorial experiment was conducted to explore these two factors' influences. Class A used neither of the two factors, Class B used Factor 2, Class C used Factor 1, and Class D used both factors.

Study 4 (April 2018 – June 2018)
This study was an extension of Study 3 and aimed to enhance progressive knowledge building using the refined IFM and a co-designed collective journey of knowledge building, which were applied when students were learning *Human Input and Output*. Classes A and B were the comparison classes and used the original IFM, which provided the same learning environment as Class C in Study 3, whereas Classes C and D, as experimental classes, used the refined IFM and took part in the co-designed collective journey of knowledge building.

Table 1 illustrates the design challenges, learning problems, knowledge-building goals, and key designs of the design trajectory.

Table 1: Design trajectory of knowledge building over two years

Study	Challenge	Learning problem	Knowledge-building goal	Key design
1	Knowledge building culture	How to work like researchers to collaborate with peers?	Idea-sharing and idea improvement	• Engagement in sharing and improving ideas
2	Intensive thread building	How to work like research groups to develop specific research topics?	Theory building	• Whole classroom meta-discourse • Offline group meta-discourse
3	Extensive thread building	How to work like researchers as a community to pursue different but related ideas?	Symmetric knowledge advancement	• Fixed/interactive/opportunistic collaboration • The group-level IFM for visualizing similarities and differences in ideas of different groups
	Collective ideas mapping	How to identify the current state and future direction of community knowledge?	Collective cognitive responsibility	• The community-level IFM for visualizing collective ideas • Design of a community view in the Knowledge Forum
4	Progressive knowledge building	How to sustain progressive knowledge building?	Progressive knowledge building	• A co-designed collective journey of knowledge-building • The knowledge building-level IFM for visualizing boundaries of ideas

Data sources
Multiple data sources were collected across the four studies, including pre-/post-science learning tests, KF notes, interviews, and questionnaires.

Analyses and results

RQ1: Did students improve on collective knowledge over time with progressive designs?

Based on knowledge-building research on KBDeX (Oshima et al., 2012), a higher Total Degree Centrality (TDC) means a denser network of domain keywords and discourse, denoting more collective knowledge advancement (Oshima et al., 2017). Using the KBDeX word networks, we can track how different groups evolved in their collective KF work across phases and studies. Figure 3 shows the changing word networks of Class D exported from KBDeX across studies, with an upward trend in the TDC and network density. Class D shared the same pedagogy design with all the other classes in Study 1; acted as a comparison class in Study 2 (adopting the whole classroom meta-discourse rather than the offline group meta-discourse); used both IFM and the rising-above community view in Study 3; and employed both the co-designed collective journey of knowledge building and the refined IFM in Study 4. More interestingly, Class D's network was more decentralized before Study 3 when it acted as a comparison class. Afterward, both its TDC and network density increased over time. These results indicate that students promote collective knowledge advancement over time, particularly in the last two studies.

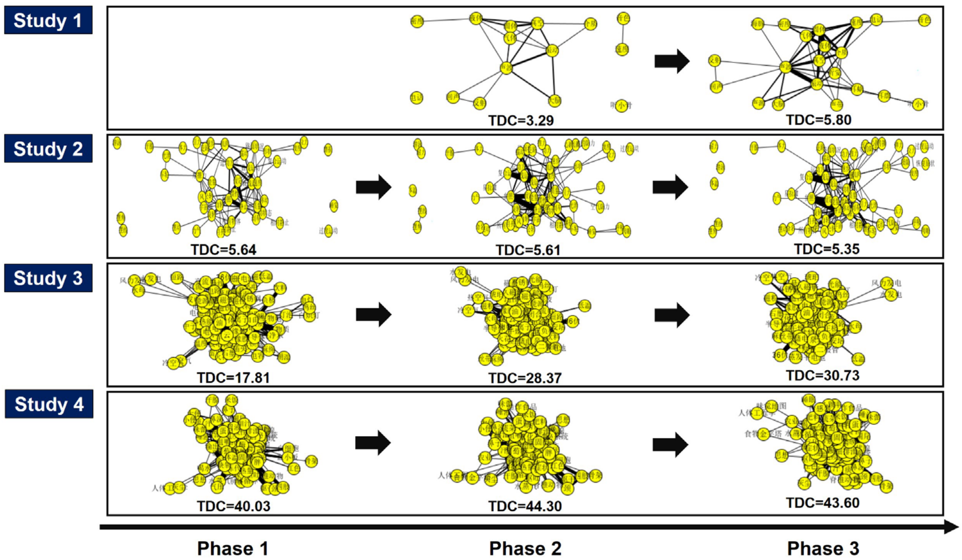

Figure 3. Changing word networks of Class D across studies

RQ2. What characterized students' epistemic understanding of knowledge building, and what was the developmental trajectory of their epistemic understanding across studies?

To investigate epistemic understanding and specifically, how students understood the goals and processes of knowledge building, and challenges they faced and solutions proposed, we interviewed around 30 students in the first three studies and collected written questionnaires using similar questions from 211 students in the final study. A set of codes was then developed and used by a second-rater to code all the transcriptions of students' answers. The inter-rater reliability was .79 for goals and processes and .80 for challenges and solutions (Cohen's kappa).

Understanding of knowledge building goals and processes

Students were required to answer several similar questions in each study, including "What did you think knowledge building is?" and "What is your biggest change in the process of knowledge-building learning?" Qualitative coding of students' responses resulted in five major levels (Table 2).

Table 2: Levels of epistemic understanding of knowledge-building goals and processes

Level	Goal	Process
1	Gain more knowledge	Like a *solitaire game*: ask a question, answer it, and then ask a new question.
2	Get the right answer	Like *climbing stairs*: ask a question, answer it, and then ask a new question at a higher level.
3	Develop ideas	Solve problems, improve ideas, and pursue sustained inquiries.
4	Collective cognitive responsibility	Promote the advancement of collective knowledge, such as synthesis, shared regulation, and lending support.
5	Progressive knowledge building	Ask a question → Hypothesize/Propose a theory → Find evidence → Make a conclusion/Improve the theory → Ask a new question. Every process was conducted in the community through group communication and peer review.

Reflection on knowledge-building challenges and solutions

Students were required to answer similar questions in each study, such as “What impressed you most in the learning process?” “What experiences make you like a scientist?” “If other students want to conduct knowledge-building learning, what advice do you want to give them?” and “What do you want to get from knowledge building for your future study?” Qualitative coding of students’ responses also resulted in five major levels, which were consistent with Table 2. Three considerations for progressive knowledge building were also identified as synthesis and sustained inquiry, group communication and peer review, and community and individual development.

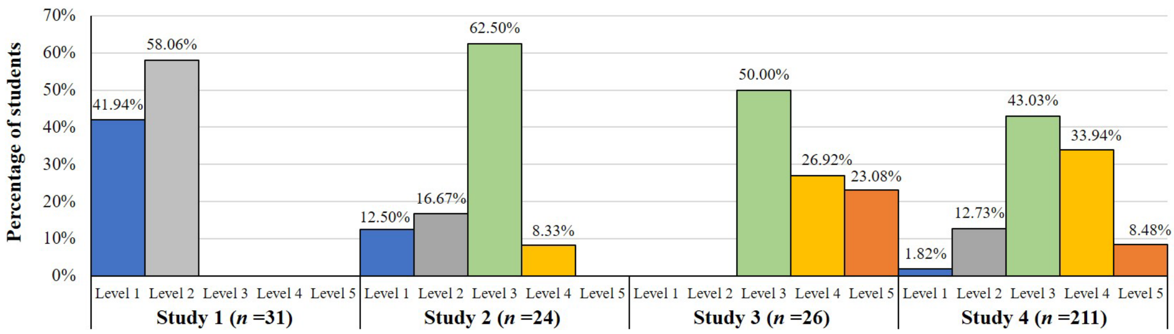
Synthesis and Sustained Inquiry. Some students answered that they should focus on synthesizing collective ideas. For example, when being asked, “Which experiences make you like a scientist in the process of knowledge-building learning?” student c707 answered that “Synthesize ideas as much as possible.” Some students perceived knowledge-building challenges as creating new questions and hypotheses. For instance, concerning the question “If other students want to conduct knowledge-building learning, what advice do you want to give them?” students c724 and c338 answered, “You have to learn to ask questions and do not obey authorities” and “Hypothesize like a little scientist, do not be afraid of making mistakes” respectively. More profoundly, student c703 unpacked the relationship between synthesis and sustained inquiry, “When conducting knowledge-building learning, they (new learners) should build on our existing knowledge (KF writings) and spend more time in new fields, to create new knowledge better.” These results indicate that conducting a sustained inquiry based on the synthesized ideas might be effective in progressive knowledge building.

Group Communication and Peer Review. Some students reported that the challenge was to enhance group communication and collaboration. For instance, in terms of the question “What impressed you most in the learning process?” student c752 claimed that “Conduct an experiment with other groups and discuss with classmates.” More profoundly, some students believed the challenge was to conduct a peer review on the theory’s scientific nature through communication and collaboration. For instance, when being asked, “If other students want to conduct knowledge-building learning, what advice do you want to give them?” student c740 proposed that “Each student first asks a question, then the students who ask the same questions are assigned to the same group. After a few weeks, students from different groups can communicate and question each other.” These results indicate conducting group communication for peer review as another possible way of progressive knowledge building.

Community Development and Individual Development. Some students perceived that the challenge was to promote collective knowledge advancement. For example, student c703 reported that “When learning *Human Input and Output,* they (new learners) should build on our existing knowledge (KF writings) and spend more time in new fields, to create new knowledge better.” In contrast, some focused on individual development. For instance, student c733’s answer to the question “What do you want to get from knowledge building for your future study?” was, “I want to create a model to promote my knowledge-building learning.” More profoundly, student c729 revealed how to deal with the relationship between the community and individual development by answering that “I want to create a new KF view to visualize my learning process.” These results demonstrate that contributing to collective knowledge advancement would benefit individual learning, while a clear understanding of individual learning processes would, in turn, promote progressive knowledge building.

Developmental trajectory of epistemic understanding

We calculated the percentage of each level from each study to identify the developmental trajectory of students’ epistemic understanding (Figure 4).



Note. Level 1: gain more knowledge; Level 2: get the right answer; Level 3: develop ideas; Level 4: collective cognitive responsibility; Level 5: progressive knowledge building.

Figure 4. Percentages of different levels of students’ epistemic understanding across studies

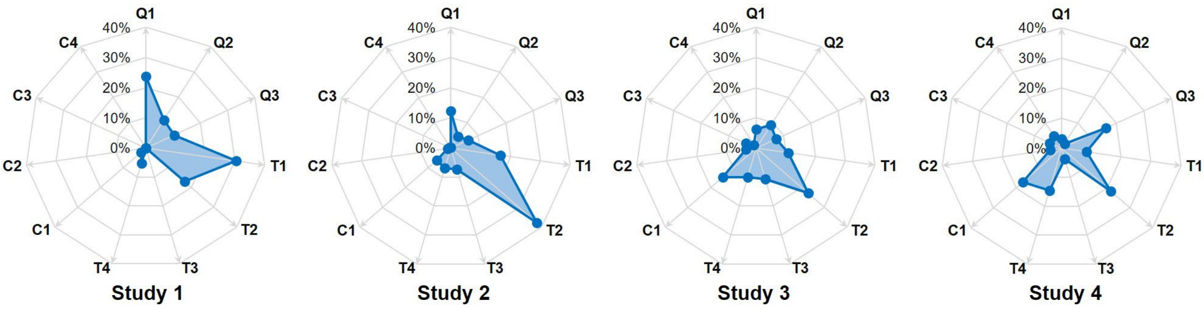
Results show that students understood knowledge building at relative lower levels in Study 1 (i.e., gaining more knowledge or getting the right answer). More than half of students considered it as a process of developing ideas in Study 2, while a significant quarter perceived it as collective cognitive responsibility or progressive knowledge building in Study 3. Notably, even in the large sample-size questionnaire analysis in the final study, a significant one-tenth of students identified knowledge building as progressive knowledge building. These results suggest that students' epistemic understanding developed from idea-sharing to theory building, collective cognitive responsibility, and finally to progressive knowledge building.

RQ3. What characterized students' engagement on Knowledge Forum, and what was the interplay among their epistemic understanding, Knowledge Forum engagement, and knowledge advancement?

Student engagement on KF in iterative studies (Studies 1-4)

We adopted KF log data (e.g., #notes created) to assess students' KF participation and interaction. Take Class D as an example who created an average of less than 2 KF notes in Study 1 and less than 7 notes in Study 2, while around 15 notes in Studies 3 and 4. In the final study, the average numbers of notes created, notes built on, notes read, scaffolds used, views worked, and references used were 13.67, 6.92, 110.02, 21.62, 6.77, and 3.83, respectively. These figures reveal students' improved KF participation and interaction over time.

We also examined the depth of KF discourse with a coding scheme composed of several categories, including *Questioning*, *Theorizing*, and *Community*. These categories depict cognitive, metacognitive, social, and community aspects of knowledge building (Figure 5). Two raters independently coded about 30% of all the notes. The inter-rater reliability was .75 for *Questioning*, .88 for *Theorizing*, and .79 for *Community* (Cohen's kappa). According to Figure 5, students showed low-level *Questioning* (Q1) and *Theorizing* (T1) in Study 1, an improvement of *Theorizing* (T2) in Study 2, usage of *Community* in Study 3, and the abilities to use high-level *Questioning* (Q3), *Theorizing* (T4), and *Community* (C3 and C4) in the final study. These results indicate students' engagement in progressively deepening discourse over time. Previous qualitative analyses of Studies 3 and 4 also demonstrate the developmental patterns of students' KF discourse, such as *Community-bridging knowledge* (C1) → *Community-synthesis* (C3) → *Questioning-sustained inquiry* (Q3) → *Theorizing-improving an explanation* (T4) (Feng et al., 2020). This analysis can be used to examine longitudinal changes for 4 studies.



Note. *Questioning*: Q1= *fact-oriented;* Q2= *explanation seeking;* Q3= *sustained inquiry. Theorizing:* T1= *simple claim;* T2= *proposing an explanation;* T3= *supporting an explanation;* T4= *improving an explanation. Community:* C1= *bridging knowledge;* C2 = *shared regulation;* C3= *synthesis;* C4= *lending support.*

Figure 5. Percentages of knowledge-building discourse moves used by Class D across studies

Relationships among epistemic understanding, KF engagement, and knowledge advance (Study 4)

Correlation Analysis. We focused on Study 4 and examined the interrelationships among epistemic understanding, KF engagement, collective knowledge advancement, and scientific understanding. Table 3 shows the correlations among students' epistemic understanding, KF engagement, collective knowledge advancement, and scientific understanding of Study 4, involving students who participated in the questionnaires on epistemic understanding (n = 211). Students' epistemic understanding of knowledge building referred to scores of the combination of students' understanding of knowledge building goals and processes and challenges and solutions. Their engagement on KF included: (1) KF *interaction* (i.e., #notes created, #build-on notes, #notes read, #scaffolds used, #views worked) and KF *metacognition* (i.e., #reference used) based on factor scores of KF log data derived from factor analysis, and (2) depth of KF discourse scores based on the coding of KF writings, including the higher-level scores (i.e., Q3, T3, T4, C1, C2, C3, and C4). Collective knowledge advancement was denoted by students' contribution to collective knowledge advancement based on TDC derived from the KBDeX note network. Moreover, students' scientific understanding and prior scientific understanding were represented by their post-test and pre-test results, respectively.

Table 3: Correlations among epistemic understanding, KF engagement, and knowledge advancement (n = 211)

Variable	1	2	3	4	5	6
1.Epistemic understanding	-					
2.KF *interaction*	.36***	-				
3.KF *metacognition*	-.09	.00	-			
4.Depth of KF discourse	.36***	.18*	.11	-		
5.Collective knowledge advancement	.23**	.68***	.10	.30***	-	
6.Prior scientific understanding	.10	.01	-.11	.02	.13	-
7.Scientific understanding	.44***	.36***	.00	.30***	.34***	.42***

Students' contribution to collective knowledge advancement showed significant correlations with their epistemic understanding ($r(120) = .23$, $p = .010$), KF *interaction* ($r(184) = .68$, $p < .001$), and depth of KF discourse ($r(184) = .30$, $p < .001$). These results suggest that higher epistemic understanding, KF *interaction*, and deeper usage of discourse moves were related to collective knowledge advancement.

Students' scientific understanding displayed significant correlations with their prior scientific understanding ($r(187) = .42$, $p < .001$), their contribution to collective knowledge advancement ($r(174) = .34$, $p < .001$), and their epistemic understanding ($r(133) = .44$, $p < .001$). These findings indicate that students' epistemic understanding and their contribution to collective knowledge advancement were correlated with scientific understanding.

Path Analysis. We also employed a path analysis testing the interplay among students' epistemic understanding, KF engagement, collective knowledge advancement, and scientific understanding. As predicted, these variables might be related, as shown by the path model in Figure 6. With a sample size of 211, the hypothesized path model was analyzed by AMOS 19. Results show a good fit: TLI and CFI were above .95, Chi-square was not significant, and RMSEA was less than .08 (Table 4). According to Figure 6, students' epistemic understanding predicted their KF *interaction* and depth of KF discourse, which further influenced collective knowledge advancement and scientific understanding. Furthermore, students' epistemic understanding also directly predicted their scientific understanding.

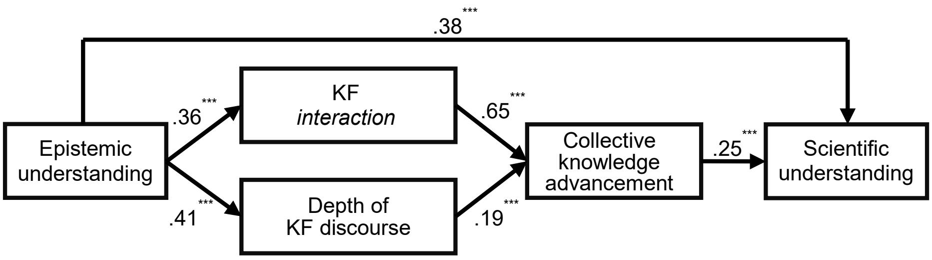


Figure 6. A path model indicating the prediction of epistemic understanding on knowledge advancement mediated by KF engagement

Table 4: Goodness of fit indices of the path analysis model

	$\chi2$	*df*	*p*	TLI	CFI	RMSEA	RMSEA 90% CI
Path model	6.73	4	.15	.95	.99	.06	.00-.13

Note. Structural equation modeling was applied to the analysis. TLI = Tucker-Lewis index; CFI = comparative fit index; RMSEA = root-mean-square error of approximation; RMSEA = 90% confidence interval of RMSEA.

Conclusion and discussion

Most knowledge-building studies are typically conducted within one semester or several months/weeks on one specific curriculum topic. Differently, this study is one of the few studies with the same cohort that spanned two years with evolving knowledge-building designs. This study built on current knowledge-building research and examined the specific role of epistemic understanding in examining how young students identified higher-level learning challenges in knowledge building. Results demonstrate that even elementary school children could propose new approaches to progressive knowledge building, such as synthesis and sustained inquiry, group communication and peer review, and community and individual development. They also presented an improved epistemic understanding of knowledge building over the four iterative studies, following a developmental trajectory of viewing knowledge building as a way to gain more knowledge, get the right answer, develop ideas, take collective cognitive responsibility, and then conduct progressive knowledge building.

The findings also reveal the positive influence of epistemic understanding on KF *interaction* and depth of KF discourse, which further promoted collective knowledge advancement and individual scientific understanding. It supports the argument of Bereiter et al. (2019) that meta-knowledge about knowledge building is needed for research advance, and this study has identified the epistemic understanding of knowledge building as one such area and illuminates on its trajectories and developmental patterns in a longitudinal design study. Epistemic understanding would be effective in strengthening epistemic agency, and students with deeper epistemic understanding are more likely to engage in productive KF discourse. Students' continued knowledge-building experience was possibly intertwined with epistemic understanding, and such reciprocal effects may facilitate their knowledge advancement. Further inquiry into how trajectories of knowledge-building designs for promoting students' epistemic understanding and progressive knowledge building will be conducted.

Picturing Worlds of Inclusion: Visual Analysis of Preservice Teachers' Representations

Christopher P. Ostrowdun, University of Calgary, chris.ostrowdun@ucalgary.ca

Abstract: Visual representations are one modality that can afford unique pedagogical opportunities for learning and as a data source in scholarship. This paper compares visual representations (drawings) and written descriptions of inclusion and disability created by preservice teachers. Analysis of the descriptions revealed the participants often noted principles and stances toward inclusion while the drawings showed how inclusion manifested in power structures, social relationships and interactions, pedagogy, and inclusive practices. The lenses of figured worlds and visual analysis were used to unpack how the participants assigned significance to students, teachers, acts, and outcomes. This paper discusses how representations revealed key nuances into how preservice teachers understood inclusion that were not apparent from written descriptions alone. This paper extends prior uses of representations in the Learning Sciences in math and science contexts to consider their application in addressing issues such as inclusion and disability, and as a tool for exploring figured worlds.

Introduction

Different modalities convey and afford different types of information and meaning making processes. Visual representations, such as drawings, are one modality that has received relatively limited attention in the Learning Sciences, particularly outside of science and mathematics contexts. Representations offer unique ways for students to construct meaning and understanding as well as researchers in interpreting students' perspectives.

This paper reports on how student generated representations and visual discourse analysis combine in revealing rich insights into students' perspectives, that may not be apparent through other modalities. In particular, I compare preservice teachers' representations of inclusion with their written descriptions of inclusion as part of their teacher training at a Canadian university. I use figured worlds as an organizing framework to identify how preservice teachers understand inclusion as conveyed through their representations and written texts. This continues prior efforts in the Learning Sciences to use representations in mathematics and science education (diSessa, 2004; Medina & Suthers, 2013) to support engagement with complex content as well as investigations of representational processes in autobiographical digital art production (Halverson, 2013).

This work contributes to investigating more about preservice teachers' emergent understanding (Walkoe & Luna, 2019), by using representations as in-progress snapshots of preservice teachers' perspectives toward inclusion. Teachers' beliefs, worldviews, and perspectives shape teaching practices (Santagata et al., 2018; Silverman, 2007), warranting the need for opportunities for preservice teachers to consider and reflect on their perspectives alongside training on inclusive strategies and policies. Previous research indicates preservice teachers have positive sentiments toward inclusion (Markova et al., 2016) but less is known about the nuances of preservice teachers' perspectives such as how inclusive practices address social interactions or how epistemological perspectives shape inclusive practices. As Savolainen et al. (2012) found, while teachers can be positive toward inclusion, how inclusion could manifest in practice can vary considerably. Representations offer an opportunity for preservice teachers to better understand their own perspectives, advances in teacher education, and contributions to scholarship.

Purpose

This paper builds on prior work (diSessa, 2004; Halverson, 2013; Medina & Suthers, 2013) in the Learning Sciences around representations to apply a sociocultural lens to topics, such as inclusion, and how representations reflect figured worlds. Comparing preservice teachers' visual representations with their written descriptions highlights different aspects of their thinking and understanding of inclusion. This paper addresses two questions: How do preservice teachers understand inclusion? What do preservice teachers' visual representations and written descriptions convey about figured worlds of inclusion?

Theoretical framework

More than a playful activity, creating representations is an intentional act of design, "arising out of the cultural, social and psychological history of the sign-maker, and focused by the specific context" (Kress & van Leeuwen, 2006, p. 7) in which it is produced. Creating representations requires decisions about what to include and what to leave out, and real cognitive work to abstract ideas and convey them in visual forms (Halverson, 2013). Whether simple or complex, a representation shows not only direct meanings and ideas through depiction but also the histories and experiences of the creator that informed their artistic decisions. As a form of discourse, representations are "a structure of messages within which are embedded social conventions and/or perceptions, and which also present the discourse communities … [of the] maker" (Albers, 2007, p. 84). Like written texts, conventions have formed around how representations are created and interpreted, which Kress and van Leeuwen (2006) referred to as visual grammar to encompass how "depicted elements – people, places and things – combine in visual 'statements' of greater or lesser complexity and extension" (p. 1). Moreover, visual grammar is independent of skill or expertise in fine arts, making it useful for studying preservice teachers' representations.

With visual grammar to interpret representations, figured worlds are a way to organize their meanings. Figured worlds are "socially and culturally constructed realm[s] of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). Figured worlds reflect taken for granted assumptions about contexts, their participants, and what happens within them. For instance, in the world of schooling there are recognizable norms about how students and teachers interact, what classrooms look like, and what teachers and students do. I use figured worlds as a lens to examine how preservice teachers represent figured worlds of inclusion. Figured worlds is a useful framework to understand how people assume orientations to participate in a given context (Jurow, 2005), such as preservice teachers' orientations to inclusion.

Methods of data collection and analysis

As part of a larger design-based research project (Ostrowdun, 2020), preservice teachers enrolled in a Bachelor of Education course were tasked with creating drawings (representations) of inclusion. This paper reports on drawings preservice teachers created during a 50-minute session, using paper and markers, in the first week of the semester. The preservice teachers were instructed to "draw inclusion within a learning context" and provide a brief (<150 words), written description of their drawing. The prompt was intentionally open-ended with no stipulations of what should be drawn. Preservice teachers then discussed their drawings and perspectives toward inclusion with peers in small groups. Drawings from 34 consenting preservice teachers (who were also interviewed in the larger study) were collected and scanned for analysis. Note, to align with the larger study, my analysis was delimited to drawings with a focus on inclusion in terms of disability.

The drawings were analyzed using semi-open coding for attributes, adapted from Albers (2007) and Kress and van Leeuwen (2006), such as people, activities, locations, size of drawn elements, colours, composition, and relationships between elements. These components make up a visual grammar based on historic conventions and patterns in visual design independent of specialized artistic skills or talents. I similarly examined the written descriptions for how the participants described and assigned value to people, locations, actions, principles in terms of inclusion. The drawings and descriptions were then compared for how each modality represented aspects of figured worlds of inclusion. Data from the larger study was also used to triangulate and substantiate the findings.

Findings

While all participants expressed a positive sentiment (e.g., depictions of smiles, collaboration, hearts) toward inclusion, there were subtle, yet meaningful, differences among the drawings and descriptions. Most drawings (n = 23) conveyed inclusion through a narrative or scene, such as what someone might see if they walked into a classroom in-action. The remaining 11 drawings showed more static or abstract principles and perspectives, such as multicoloured shapes connected with rainbows.

Among the 26 drawings that included people, the drawings conveyed hierarchies between students and teachers that were often unspecified in the written descriptions. Such power structures and assignments of roles can have epistemological implications, such as between teacher-centred and student-centred approaches. For instance, one drawing of a classroom depicted the teacher larger than students, fitted with masculine apparel, and in greater detail than students (a defined body shape versus stick-figures), implying a hierarchical relationship of power or expertise (Kress & van Leeuwen, 2006). The same drawing also showed some students working alone using specific resources (i.e., a computer, alternative seating, smartboard) around the edges of the classroom while the teacher and other students were in the centre, positioning users of such resources at the margins. Following conventions of composition, this arrangement assigns value to the central elements (Kress & van Leeuwen, 2006). The written description mentioned supporting diversity and facilitating teacher-led and independent learning, but it did not address the potential sociocultural implications of placing certain students at the margins. This was a figured world that valued access to tools and resources but gave less consideration for social interactions or positions among students and the teacher.

Five drawings also "assign[ed] functions and meanings to space and spatial arrangements … [as a] form of social control" (van Leeuwen, 2008, p. 97). For example, one drawing showed a teacher standing in front of a board, two students at a desk in front of a smiling teacher, and one student leaving the room. The description explained the student leaving was upset, and one of the seated students as struggling. The struggling student was also sitting hunched over the desk on an exercise ball, while the other seated student was in an upright posture looking toward the teacher and in a chair. This conveys a narrative of students with accommodations as also struggling and physically disengaged, while the other students without accommodations do not struggle and are engaged with the teacher. As well, depicting the upset student as leaving the room establishes a figured world that privileges certain emotions within inclusive environments while excluding others, such as frustration.

The abstract drawings tended to convey more high-level principles and metaphors related to inclusion. Figure 1 depicted two brains to contrast people with a learning disability and neurotypical people. The description associated the latter with organization, time management, "proper sleep," and "the right amount of anxiet[y]." They described the former as being disorganized and a "battle … against themselves." The drawing not only matches these descriptors but amplifies them. The drawing follows a given-new, left-right composition structure (Kress & van Leeuwen, 2006). In this case the participant, who identified as having attention deficit disorder, placed their experiences on the left as *given*, while on the right was an experience novel to them. As Holland et al. (1998) noted, some worlds may be inaccessible because of social positions or identities. A neurotypical identity was not just novel but also inaccessible within the existing figured world.

The participant attributed greater value and desire to the right half, using colour (Kress & van Leeuwen, 2006), fitting text within the boxes/brain in the high-normal-low anxiety graph, and a shorter checklist (showing only checkmarks). Also communicated through the drawing is a negative association with music and television, with them appearing only on the left side, while the right side conveyed narrative of order and structure. Together, the drawing and description portrayed a figured world that ascribed value to academics and organization and that inclusion was an antidote to a deficit narrative (left) toward a desired narrative (right).

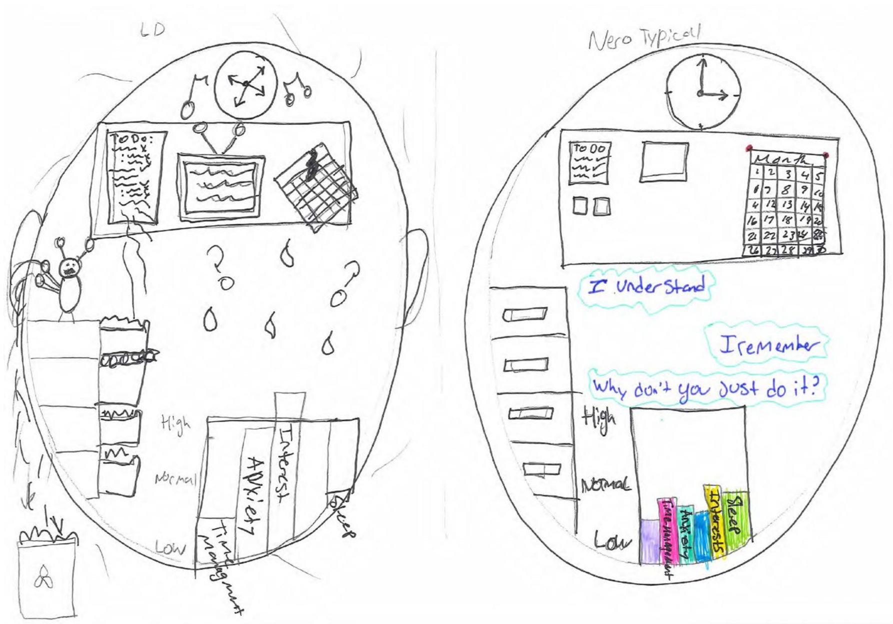

Figure 1. Abstract representation of a learning disabled brain (left) and neurotypical brain (right).

All participants expressed broad support for inclusion through their drawings and descriptions. Deviations became apparent upon closer inspection of the drawings and descriptions with each conveying different aspects of figured worlds. The written descriptions often made statements about principles, dispositions, and general stances toward inclusion such as "support all learners," "embracing differences," "equal opportunit[ies] to learn," and "accommodate … varying needs." The drawings, particularly of classrooms, showed how the participants envisioned their perspectives might manifest in specific scenarios. Through examining composition, proportions, spatial positioning, and rendered elements, the drawings conveyed insights about power structures, relationships, epistemological stances, and teaching practices. These fleshed out key details of how the participants understood figured worlds and the types of narratives associated with them. The descriptions articulated elements of inclusion while the drawings showed relationships among the elements and which elements were prioritized over others.

Implications and conclusion

Complementing prior efforts examining (preservice) teachers' perspectives toward inclusion (Loreman & Earle, 2007; Markova et al., 2016), representations can offer additional insights into how they characterize figured worlds. Analysis of the representations reveals nuances not only about how preservice teachers understand inclusion but also how they conceive enacting inclusion. In particular, the representations show how power was wielded and conveyed by teachers in terms of disability, which is a growing area of focus in the Learning Sciences when developing theories and innovations of learning (Esmonde & Booker, 2017). With figured worlds as orientations to every-day actions, representations offer a rich layer of understanding into how preservice teachers consider "which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). As a pedagogical tool, creating and discussing representations can also encourage preservice teachers to bring awareness to their emerging perspectives and to reflect on implications for practice (Phillipson & Forlin, 2011). Collectively, the findings extend previous uses of representations in the Learning Sciences to contexts beyond science and mathematics as an insightful modality and approach to supporting student learning and scholarly understanding.

Abstract: Multiple representations of a phenomenon can support science learning. Legitimizing diverse representational resources can also create more equitable learning environments. In this paper, we present cases from a year-long professional development with in-service elementary teachers designed to support science teaching with representations, and we closely analyze how two teachers prioritized making space for students' diverse ideas and practices as a foundation for these understandings. Through this work, we identified practices and purposes for connecting representations and illustrated how teachers addressed tensions between accountability to standards and creating space for students' resources.

Objectives and significance

Leveraging multiple representations (e.g., language, gesture, drawing) can support science learning by deepening students' conceptual understanding and disciplinary engagement (Lehrer & Schauble, 2015). Cycles of experimentation and discussion can help learners build explanations of phenomena as they re-represent phenomena in new ways (Danish, 2014). Moreover, working with multiple representations shapes inquiry (Gouvea & Passmore, 2017), because different representations foreground different concepts and practcies. Legitimizing diverse resources (e.g., languages other than English, non-linguistic representations) can also create more equitable learning environments for students from non-dominant backgrounds, including students classified as "English learners (ELs)," because expanding the range of resources considered "appropriate" for science learning allows students to access their full representational repertoires for sensemaking (García & Li, 2014).

To support students' work with representations, researchers have explored teachers' perceptions (e.g., Reiser et al., 2017) and use (Thompson et al., 2019) of representations. Teaching with representations can be challenging, because it requires teachers to unpack features of representations (Eilam & Gilbert, 2014) and establish and refine relationships between representations (Schwarz et al., 2012). Moreover, teachers often experience tensions between accountability to science standards (e.g., NGSS Lead States, 2013) and creating learning environments that are meaningful for students (Manz & Suárez, 2018). These tensions arise from time constraints and concerns about reinforcing "misconceptions," and they can be homogenizing forces that lead teachers to emphasize canonical ideas, suppressing diversity in students' ideas as legitimate resources for sensemaking (Guy-Gaytán et al., 2019). In this paper, we present cases from professional development (PD) with in-service teachers designed to support teaching with representations. Rather than distinguishing between types of representations, our focus is on how teachers leveraged multiple representations in service of science learning.

Methods

We analyze data from a PD that was designed and facilitated by the authors and members of a larger research team. Rather than evaluating specific features of the design, we analyze data as a collection of cases (Yin, 2014) to consider how teachers used representations to support learning, and, in some cases, create more equitable opportunities for learning. Nine in-service elementary teachers from a metropolitan public school district in the southeastern US participated in the PD during the 2019-20 school year. After a five-day summer workshop teachers participated in four after-school PD sessions during the academic year. In these sessions, teachers engaged in student work analysis (Little et al., 2003) during *gallery walks* and discussed video of their classrooms during *video clubs* (Sherin & Han, 2004). In this paper, we analyze video recordings of PD, classroom observations, and interviews with teachers. Our analysis considers each teacher's practices as an exploratory case of how teachers used multiple representations. From teachers' discourse, we developed codes for their purposes and practices for using multiple representations. Then, we looked for trends in our codes across cases, as well as examples of unique practices.

Findings

In the full study, we look across all nine elementary teachers' practices and purposes for connecting representations. Here, we focus on two of the third-grade teachers (Jack and Sarah), because they prioritized students' diverse ideas and practices as a foundation for building shared, canonical science understandings.

Jack: Amplifying fit between experiment and phenomenon with questioning

In a unit about magnets, Jack invited students to explore their unique ideas about a phenomenon by designing an experiment to model the phenomenon. Jack connected students' ideas to canonical understandings with questioning and modeling; he encouraged students to share their ideas as they worked on their experiments, and he used questioning to press students to more closely map their ideas and experiments to the phenomenon. In PD sessions and in interviews, he explained that as students worked to revise their experiments, they also revised their ideas about the phenomenon and about magnets, supporting canonical understandings aligned with standards.

Jack's unit was anchored with a phenomenon from a news video: a reporter showed that a car parked at the bottom of "Magnetic Hill" would roll backward uphill when in neutral. In fact, the car rolling "uphill" was an optical illusion. Though the phenomenon is *not* caused by magnets, Jack explained that investigating these claims allowed students to explore concepts like magnetic fields, attraction, and repulsion. Jack used several tools to track students' theories. Collectively with students, Jack created and revised a list of theories about the phenomenon on a shared model of their evolving thoughts posted on a board visible to students. Individually, students tracked their theories in science journals. Combining the list with the journals was one way that Jack created space for students to explore unique ideas while building a shared understanding.

In the lesson we observed, Jack created space for students' ideas and practices by inviting students to design experiments. Jack opened the activity by reminding students students of the five theories the class had suggested about why the car rolled uphill. Jack prompted students with, "which [theory] is most true to you, and which do you want to prove today?" Although they tested different ideas, students used the same experiment design template, a graphic organizer for attending to science practices. In class discussions and one-on-one, Jack repeatedly asked students about parts of the template: "what do [the materials] represent?" and "how does that help you prove your theory?" This questioning helped students develop and make progress on individual experiments and build a shared understanding of a disciplinary practice – experimental design. Throughout the lesson, Jack used questioning to press students to consider fit between their experiments and the phenomenon. When one student shared his progress (by moving a horseshoe magnet above his car, he could move his car uphill), Jack asked, "the magnet you're holding is what?" The student replied, "asteroid." Jack said, "but the asteroid is under the road," challenging the student to more closely model his idea by placing the horseshoe magnet below the ramp rather than above the car. Not all of the students were testing the same theory; still, this feedback could be generalized to their experiments as they considered how their model mapped to their idea and the phenomenon.

Later, students connected the experiments to their ongoing work by annotating their journals with their results. In his post-observation interview and in PD, Jack explained that he brought these representations together because they helped students build understanding from a foundation of personally meaningful ideas and practices. He said the experiment "really challenged their thinking to change their opinion." He explained, "They really had to think, what am I going to do with this stuff? How am I going to use it to prove the phenomenon?…it's really connecting for them about how the magnets are used, of them being able to use the magnets now, not just *see* them in action but *feel* them." Jack saw these experiences as crucial – each student needed to explore ideas individually to revise ideas and contribute to the classroom's shared understanding of magnets. In addition, Jack emphasized having students use journals to bring together representations, including the experiment, to track their thinking. Tracking theories helped students "compare and contrast their thinking… to define the holes in their thinking." Thus, Jack used multiple representations to invite students to explore their unique ideas by designing and carrying out experiments and to help students build a shared understanding of magnets. As a bridge between students' ideas and canonical understandings, Jack used questioning to help students critically examine their models and to map their ideas to the phenomenon, simultaneously making sense about magnets more broadly.

Sarah: Amplifying students' representations

Like Jack, Sarah invited and valued students' diverse ideas. However, rather than using questioning and modeling to press students toward canonical ideas, Sarah elicited students' representations, and she selected representations that aligned with canonical ideas to share with the class. In this way, she used students' unique experiences and ideas as a bridge to standards. In a unit about pollination and the structure-function relationship between bees and flowers, Sarah used multiple representations to support students' understanding. To connect activities in the lesson, Sarah used phrases and embodiments (full-body movements that enacted parts of the phenomenon). During the lesson, most sensemaking was done through talk, although students also had opportunities to write (making predictions) and participate in an experiment. At the end of the lesson, students completed exit tickets that connected multiple lessons by asking the same questions daily, allowing students and Sarah to trace how the students' ideas about pollination changed as they interacted with representations.

In this lesson, Sarah supported canonical science learning by leveraging students' ideas and representations, focusing on students' language. For example, Sarah used a phrase from one student's exit ticket to guide sensemaking. She opened the lesson by reminding students of their anchoring phenomenon. She then projected the exit ticket on the board and encouraged students to discuss what they saw, focusing students on the drawing that depicted and labeled a bee's "hair" as a "scratchy sweater." Sarah asked students what a scratchy sweater feels like, and they decided it doesn't feel good ("hairy" or "pokey"). When Sarah asked what students thought "scratchy sweater" was about, they said it might describe how the bee picks up pollen. Sarah later performed a "scratchy sweater" embodiment (shrugged her shoulders in discomfort). This combination of a phrase and embodiment offered students resources for sensemaking about pollination grounded in their experiences. Sarah continued to use phrase-embodiment pairs in students' work with other representations (video, experiment) and throughout the lesson. For example, as Sarah and the students were making sense of how bees get pollen on their bodies, students suggested that "because the bee tries to go down" to the center of the flower it "bumps into the [pollen duster]" and "rubs against it." Sarah encouraged students to embody the bee "buzz buzzing" and used a student's language ("rubbing against it") to embody the bee "rubbing against" the pollen duster. In this way, Sarah used students' language as a starting point to engage in imaginative embodiment as the class tried to make sense of the bee's role in pollination. Throughout, she was drawing on language students were using to create a shared repertoire of embodiments and phrases guiding their collaborative sensemaking as a classroom.

In PD and interviews, Sarah explained that she designed this lesson to capitalize on students' shared histories and to build new histories of sensemaking. Sarah said representations should "build on each other, elicit things from kiddos" to pull out "science concepts along the way" and to "give really good opportunities for kids… to show what they're thinking." She described how the exit ticket and students' prior experiences with scratchy sweaters laid groundwork for sensemaking during the experiment and shifted authority from herself to the students for identifying and naming ideas; student-generated representations allowed students to "teach the class" so students could "learn through [each other] versus me telling them." Her emphasis was not on assessment, but the process of sensemaking: students making connections to science ideas "along the way" and discussing their thinking. Thus, Sarah used representations as a way to elicit students' ideas as resources, offer students opportunities to learn from each other (rather than positioning the teacher as the sole authority in science), and to connect students' lived experiences to natural phenomena as a way to build explanations.

Discussion, conclusions, and implications

Both Jack and Sarah's cases show potential for creating more equitable opportunities for science learning. In Jack's case, third graders were given the option to use multimodal resources when designing their experiments, an approach that has been shown to support learning for multilingual students in particular (Williams, 2020). In addition, Jack encouraged students to explore their unique ideas in their experiments. This approach could communicate to students that each of their ideas was a valuable starting point for sensemaking. Jack hoped that this lesson would build students' confidence in themselves "as scientists," because they controlled the design and interpretation of their experiment (Haverly et al., 2020). Rather than reinforcing "misconceptions," playing out their initial ideas in the context of Jack's questions enabled students to bridge from their initial ideas to canonical understandings. However, Jack also identified challenges associated with this approach. He acknowledged that this process took a lot of time, because each student needed to individually test their ideas multiple times. It is possible that in such a student-driven context, some students might have more opportunities to test their ideas (and receive feedback from Jack) than others, and some students could be overlooked by their teacher. Questioning about their individual experiments could also be intimidating for students, who might be reluctant to share "incorrect" ideas. While we did not observe these issues in Jack's classroom, we recognize that with this approach it would be important to attend to *who* is participating and *how* they are participating (McKenney, 2018).

In Sarah's case, third graders also had the opportunity to use multimodal representations to express unique ideas (specifically, drawing and writing on their exit ticket). However, students' responses were slightly more constrained, because they needed to produce a more formalized response on paper (rather than through talk and "hands-on tinkering," as in Jack's lesson). Because students turned in this assignment at the end of class, they might also have felt more pressure to use "academic" (formal English) language (Flores & Rosa, 2015). These restrictions could suppress ideas if students are not confident in expressing their ideas in this way. In addition, because Sarah selected certain students' phrases or drawings to amplify for the class, it is possible that some students might have felt that their work was not as valuable as their peers' because their work was not shared. At the same time, Sarah's approach offers a more efficient way to address the tension between accountability to standards and students' ideas and practices. In Sarah's classroom, students had the opportunity to express their ideas, and Sarah used these ideas as a foundation for shared sensemaking. Sarah explicitly drew upon ideas that she thought were likely to be familiar to students, providing opportunities for students to see their experiences as relevant to science. Because Sarah selected specific ideas to share (rather than working from all students' ideas), she could more quickly move from students' ideas to canonical ideas. Moreover, by creating shared embodiments and phrases to discuss with the whole class, it was likely easier for Sarah to check on students' engagement and understanding. Thus, these shared representations might have made it easier for Sarah to monitor and respond to students' thinking and to build on their experiences as resources for science learning.

We presented these two cases because each offers an approach for building shared, canonical understandings from students' diverse ideas and practices. These approaches can inform the design of learning environments and PD programs that support teachers' work with representations. To realize this potential, further research is needed to address tensions that arise from standards that prioritize canonical knowledge and practices and dominant ideologies about "appropriate" resources for learning. While it is difficult to shift disciplinary ideologies and values, this work is critical for creating equitable learning opportunities in science classrooms.

Ambitious and Equitable Science Teacher Noticing in Distance Learning

Heather F. Clark, University of California, Los Angeles, heatherfclark@ucla.edu

Abstract: Teacher noticing is immensely challenging during remote instruction mandated by the COVID-19 pandemic. I document one science teacher's noticing while teaching over Zoom using an approach inspired by Nicole Louie's (2018) work based in two theoretical frameworks – a cognitive perspective and a political and social perspective based in Professional Vision. Drawing on observational field notes, post-instruction debriefs and a retrospective interview, I identify five social practices of noticing – coding, highlighting, identifying, connecting and using knowledge. Three themes emerged to describe the potential and purpose of teacher noticing: legitimizing what student experiences "belong" in science class, normalizing the struggles faced by minoritized students during distance learning and bridging past and future lessons. My findings suggest that teacher noticing from in-person instruction does not translate to distance learning and that the practice of noticing must be re-imagined to support ambitious and equitable science teaching.

Keywords: teacher noticing, science education, distance learning

Introduction

Teachers face immense challenges to creating learning opportunities for students via Zoom instruction while distance learning is required during the COVID-19 pandemic. With many students' cameras off and microphones muted, one specific challenge is being able to anchor instruction within a detailed and comprehensive observation and understanding of students' immediate response to instruction. Noticing is an essential practice of teaching and efforts to support ambitious and equitable learning opportunities require that we understand how and what teachers are noticing as they improvise distance learning and how teachers can learn noticing to improve their practice.

Noticing is a dynamic process that involves attending to and making sense of particular events in an instructional setting (M. G. Sherin, Jacobs, & Philipp, 2011) which is profoundly influenced by a teacher's philosophical stance on their profession (Erickson, 2011) and has major consequences on the learning opportunities afforded to students (Luna, 2018; B. L. Sherin et al., 2010). Studies of noticing in classroom settings underscore the "blooming, buzzing confusion of sensory data" (B. L. Sherin & Star, 2011, p. 69) that teachers encounter; this is still true but wildly different in distance learning. Rather than students' expressions and utterances, teachers largely hear silence and see small black boxes on their computer screens particularly when those students do not have adequate access to technology. But teachers are not staring into a void; for many teachers the Zoom window sits alongside numerous applications windows that teachers use in instruction and through which students participate.

In this exploratory study, I document the noticing of one science teacher, Ms. B, as she supports her 10^{th} grade Black and Latinx chemistry students in distance learning. Rather than narrow the scope of investigation to her noticing about disciplinary ideas or identity development, I aim to identify broadly what Ms. B notices in her students' engagement and how she reasons about that noticing. This broad focus on engagement and participation allows for methodological and theoretical flexibility that can later be refined and expanded to support teachers in learning to notice in more expansive ways.

Theoretical framework

This investigation is grounded in two dimensions of noticing that distinguish the goals and commitments of science teaching. First, ambitious, reform-oriented education and noticing take students ideas seriously to guide instruction, and the reform driven by the Next Generation Science Standards (NGSS) requires teaching and noticing drastically different than historically dominant model of "teacher dominated discourse, textbook based lessons, and coverage as the main curricular principle" (Skyes, Bird, & Kennedy, 2010, p. 465). Ambitious science instruction, as proposed by Windschitl and colleagues (2012), relies on core instructional practices that are inherently social and interactional. For example, eliciting students' ideas about a puzzling scientific phenomenon can allow teachers to adapt instruction to students' interests. Second, building on work in mathematics education, equitable noticing expands the foci to participation, identity and multiple knowledge bases, and challenges systemic disenfranchisement (Hand, 2012). Equitable noticing attends to sociopolitical processes such as positioning students as capable or not and privileging some forms of participation over others. For example, Hand

(2012) describes a teacher highlighting the subjective nature of assessment practices to open a broader space to critique how competence is determined. Anchored in these two facets of noticing, I will describe an approach to theoretical triangulation that I hope will open expansive possibility for understanding teacher noticing. I plan to analyze this data using first a cognitive approach to noticing, which is more established in research, and second using a sociopolitical lens, responding to and building upon Louie's (2018) effort to revive analysis of culture and power embedded in Goodwin's (1994) Professional Vision framework. It is important to note that technology plays a major role in Ms. B's noticing. She is extremely technologically proficient and uses a wide range of digital tools, which is not true for all teachers. Additional conceptual frameworks anchored in technology and teaching could be useful for future investigations of noticing during remote instruction but are outside the scope of this exploratory study.

Cognitive perspective

To analyze teacher noticing, first I will use the conceptualization established by van Es and Sherin (2008). These scholars describe noticing as an individual cognitive process situated in the complex classroom context based on teachers determining what is worthy of attention and reasoning about what to notice. van Es and Sherin's framework includes three aspects: a) *identifying* what is important or noteworthy about a classroom situation, b) *making connections* between the specifics of classroom interactions and the broader principles of teaching and learning they represent, and c) *using what one knows* about the context to reason about the interactions. A benefit of this approach is that it emphasizes the learnability of noticing and can be used to explore teachers' learning trajectories in becoming experts at noticing. To understand Ms. B's efforts to support equitable and ambitious science learning, I analyze her noticing in terms of *identifying* student participation as noteworthy, *connecting* student participation to her objectives for learning and equity, and *using knowledge* of students and both the distance learning context and interactional moment for reasoning about the interaction.

Culture, power and professional vision

In addition to the drawing on the cognitive perspective on noticing, I aim to take up Louie's (2018) project of analyzing culture and power in teacher noticing to further describe the challenges Ms. B faces in navigating and overcoming structures of marginalization embedded in schooling and science instruction. Louie draws on the social and political facets of Goodwin's (1994) concept of Professional Vision that involves "ways of seeing and understanding events that are answerable to the distinctive interests of a particular social group" (p. 606) and "distinct patterns of noticing" (p. 170) shared by groups of professionals.

First, Goodwin portrays noticing as socially and culturally constructed as professionals use tools that make sense in their shared experiences and serve their similar goals. And second, Goodwin describes noticing as reproducing social arrangements that privilege some and marginalize others. Noticing is not politically neutral as Professional Vision is "answerable to" power, such as "what kinds of talk can and cannot be heard, who is qualified to speak the truth, and the conditions that establish the rationality of statements" (p. 626). Louie identifies Goodwin's social practice of *coding*, or "transforming phenomena observed in a specific setting into the object of knowledge that animates the discourse of a profession" (p. 606), as a type of noticing practice that reduces complexity and synchronizes individual noticing with culturally established standards. For example, teachers use the coding scheme of grades to interpret students and their behavior. In addition to continuing Louie's work with coding, I will also draw on the social practice Goodwin describes as *highlighting* which "makes specific phenomenon in a complex perceptual field salient by marking them in some specific fashion" (p. 606). For example, Goodwin's writing on Professional Vision describes how the police officers involved in the Rodney King trial used the practice of highlighting to link features of the trial setting to the activities being performed in the trial in order to shape the domain of scrutiny for the jury. Goodwin's third social practice of producing and articulating material representations will not be included. In this study, I draw on the concept of *coding* and *highlighting* to identify what and how Ms. B draws attention to, simplifies and foregrounds from the complex engagement of her students.

Methods

Ms. B teaches at an urban public school in a west coast city serving low-income Black and Latinx youth. The school follows a "community school" model within the district and is in a partnership with a university, but despite these resources the school (and the district as a whole) struggled with the transition to distance learning. As has been well documented, many minoritized students do not have the resources or support for schooling at home. Ms. B and I have been collaborating on co-planning community-based, equity-oriented climate change learning since 2018, and this investigation is part of an on-going, broader study of climate change teaching and learning.

Data for this study comes from three sources. First, I wrote observational fieldnotes during four class sessions focused on when Ms. B responded to student participation, including a timestamp of the interaction, the student(s) involved, a paraphrase of the utterances, a summary of visible gestures, and notes of the digital resources involved. Ms. B also saved the Zoom chat generated during class as an artifact. After each class Ms. B and I debriefed the lesson in a conversation focused on narrating the noteworthy interactional moments. These conversations were audio recorded and unscripted with Ms. B offering observations and me asking simple questions like "what happened here?". Last, a retrospective interview explored broad patterns in noticing across the classes. These data sets are inherently incomplete in much more significant and obvious ways than collecting video data of a traditional classroom setting. To describe Professional Vision, Goodwin writes that he "requires data records that preserve not only sequence of talk but also body movements of the participants and the phenomenon to which they are attending" (p. 607) which simply was no possible for me to collect. As a result, the scope of analysis is limited.

Data analysis proceeded in three steps of coding. The unit of analysis in this study is *noteworthy moments*, which are episodes of teacher-talk in response to a student idea or participation identified (either in the moment or in a post-lesson debrief) as worthy of discussion between Ms. B and me. My first step in coding was to prepare transcripts of the conversations from the post-lesson debriefs and interview and to compile discussions of each noteworthy moments across conversations with available artifacts. My second step was a preliminary, descriptive round of coding in which I identified who Ms. B interacted with, what digital platform was in use and the topic of the interaction. My third step was to look for the features described in my theoretical framework–coding, highlighting, identifying, connecting and using knowledge – to identify emerging themes for the purpose and potential of these practices.

Findings

Noteworthy moments occurred almost entirely when Ms. B responded to something a student wrote in the Zoom chat privately to her. After consolidating across my five a priori codes from the two theoretical frameworks, I have identified three themes of the purpose and potential of Ms. B's noticing. Below I describe one example noteworthy moment per theme to demonstrate how the five practices support teacher noticing.

Categorize student experiences as legitimate scientific resources

One day Ms. B was discussing air pollution as related to combustion chemistry. The Zoom chat at the moment was busy with a range of questions and comments, some on topic and some not, but two students wrote her privately in the Zoom chat about their personal experiences with air pollution and she read out loud (akin to revoicing) their contribution. One student shared that he had asthma and another shared that she has seen the city look ugly, dirty and gray. In this interaction, Ms. B is *identifying* important student participation as noteworthy from the range of participation. By revoicing and making the private public, Ms. B is *coding* these contributions as belonging in class. These practices were used to categorize student experiences as legitimate scientific resources. Ms. B's noticing drew on both her pedagogical content knowledge and her cultural and social knowledge of her students to expand the boundaries of what belongs in chemistry class to include community and family-based ideas and experiences.

Normalize the obstacles and frustrations of distance learning

Another class activity modified a participation structure that Ms. B used in-person to allow students to rotate through "stations". After explaining the activity, Ms. B asked if there were questions and student neither responded nor dove into the lesson. Ms. B identified this lack of participation as an indication that the activity was not framed well enough for students to understand the tasks, and rather than forge ahead, she *used her knowledge* of students' circumstance and took the opportunity to share how difficult it is for her to transform lessons for remote learning. In our debrief session, Ms. B described worrying about if students were logging in to Zoom on their phones rather than the preferred Chromebook, if they had poor internet connection, or if they were in a distracting space. By foregrounding her own struggles, she normalized the obstacles and frustrations of distance learning and created space for students to express their struggles. In reflecting on this moment and practice, Ms. B explained her reasoning in connection to her stance as a social justice educator and her commitment to nurturing student well-being.

Bridge past, present and future lessons

Ms. B re-visited a "word cloud" students had previously built of associations with the phrase "climate change" and one student wrote in the Zoom chat that she had contributed the phrase "pollution". Ms. B took this opportunity to call the student out by name and asked if she now knew what the chemical name of the pollutant was. The student then unmuted herself and identified the pollutant as carbon dioxide. This is an example of Ms. B *making connections* that bridge past, present and future lessons and *highlighting* the past learning that is relevant to a current activity. This required Ms. B to use her knowledge of all lessons as well as the ultimate goals for student learning outcomes. When I asked Ms. B's about highlighting previously covered concepts, she explained that she was both spiraling back and scaffolding for future lessons when a concept would be relevant again. She also explained this moment as related to her belief that her students were capable of succeeding in distance learning with the appropriate scaffolds.

Significance

The themes identified in this study suggest the ways in which Ms. B's noticing supports ambitious and equitable science teaching. Bridging lessons is a strategy for creating cohesive storylines that supports students in generating coherent explanation of phenomena which is a high-leverage practice of ambitious science instruction. Normalizing the struggles faced by minoritized students demonstrates how Ms. B's noticing attends to her students' identities and lived experience. And last, legitimizing community-based resources as scientific supports equity by disrupting the hierarchy of Western epistemologies associated with the canon of science and the NGSS. What Ms. B noticed and how she responded was shaped by a) dynamic in-the-moment interactions, b) cultural, social and political forces stretching into the past and the future, and c) her technological proficiencies. Further investigations are needed to expand an understanding of how the five identified practices of noticing shape students' experiences; I hope this exploratory study can be part of an emerging conversation and research on remote teaching and learning.

Noticing has the purpose and potential to enhance meaningful learning possibilities (Luna, 2018); supporting teachers in learning to notice in the distance learning environment can have tremendous implications for students. Of the many systemic changes that are needed in supporting low-income students of color, helping teachers anchor their teaching in students' response to instruction is essential. Findings based in both a cognitive perspective and socio-political perspective of noticing suggest that noticing used for in-person teaching does not translate to distance learning and noticing. The modalities through which students and teachers engage with each other is vastly differently and the three themes identified in this study suggest the need to re-think how teachers learn to notice. Instead of trying to replicate schools and schooling and the inequalities in these systems, the challenges of distance learning present opportunities to re-imagine how to support teachers in equitable and ambitious noticing.

What pedagogy feels like: Using rehearsal debriefs to develop pedagogical empathy

Jen Munson, Northwestern University, jmunson@northwestern.edu
Erin E. Baldinger, University of Minnesota, eebaldinger@umn.edu

Abstract: Teachers must attend and respond to students' emotions, as emotions are inherently intertwined with learning and disciplinary identity. In this study, we forward a theory that the development of *pedagogical empathy* is an inherent component of adaptive expertise, because pedagogical decision-making should be sensitive to students' emotional responses to teaching. We examine how teachers generated and used emotional data during debrief discussions following rehearsals in support of the development of pedagogical empathy. These results have implications for understanding the role of pedagogical empathy in adaptive expertise.

Teaching is characterized by the need to make in-the-moment decisions that respond to emergent student thinking and classroom conditions (Lampert et al., 2010), a capacity known as adaptive expertise. Adaptive expertise involves collecting and using a constant stream of data to make both routine and adaptive decisions about how to respond (Hatano & Inagaki, 1986). Developing adaptive expertise requires time and deliberate opportunities to learn, with attention to when routine responses are sufficient and when innovation is required (Kavanagh et al., 2020). Rehearsals of teaching, in which teachers are either rehearsing teachers (RTs) or students (non-rehearing teachers, NRTs), offer rich opportunities for developing adaptive expertise. The debrief discussions following rehearsals are also a venue for developing adaptive expertise, as participants generate data about the rehearsal experience and consider adaptations (Baldinger & Munson, 2020).

The process of developing adaptive expertise is necessarily dependent on accessing and interrogating multiple streams of data, such as students' mathematical thinking. We argue that teachers must also consider how students feel, which we refer to as *emotional data*. Emotions matter for teaching because they are inherently intertwined with learning, regulating how students engage, think, and learn (Hascher, 2010). We posit that empathy, or the capacity to notice, interpret, predict, and respond to the emotional states of others, is necessary for developing adaptive expertise in teaching. Here, we forward a theory that the development of *pedagogical empathy* (Uhing, 2020) is an inherent component of adaptive expertise, because pedagogical decision-making should be sensitive to students' emotional responses to teaching.

Principles of pedagogical empathy

Uhing (2020) defined pedagogical empathy as having two central pillars: (1) teachers understand the evolving emotions of students, and (2) this understanding influences teaching decisions. To develop adaptive expertise, it is pivotal that teachers not just understand student emotions, but that they know how those emotions influence learning. Knowing the consequences of emotions positions teachers to respond to and foster particular emotional states. For instance, if teachers notice that sharing ideas with the class triggers anxiety in some students and they understand that anxiety is an emotional state that can inhibit learning, teachers are positioned then to adapt their instruction to avoid or mitigate that anxiety. We characterize pedagogical empathy as the professional capacity to understand and use the following principles, which, together, support the development of adaptive expertise:

1. Pedagogical situations generate emotions among students (Debellis & Goldin, 2006).
2. Emotions influence learning and the development of disciplinary identities (Debellis & Goldin, 2006).
3. Under the same pedagogical situations, different students may experience different emotions (Hascher, 2010), contributing to different learning opportunities and different disciplinary identities
4. Teachers' knowledge of student emotions can productively influence pedagogical choices (Uhing, 2020) to increase opportunities to learn and support the development of productive disciplinary identities.
5. Teachers must actively seek opportunities to collect emotional data (Uhing, 2020).

Teaching with pedagogical empathy necessitates understanding and valuing the role of student emotions in learning. However, how teachers gain access to emotional data is not straightforward.

Accessing emotional data

To develop pedagogical empathy, teachers must have reliable access to emotional data; they must know how their students feel under different pedagogical conditions, data they can best gather through interactions with students (Uhing, 2020). However, in real classrooms, there are many practical and social reasons why accessing emotional data may be difficult. Rehearsals of practice can support teacher learning in part because they offer a lower-risk environment for examining teacher decision-making (e.g., Lampert et al., 2010). We argue that the debriefs following rehearsals offer a space for gaining access to student emotions, when students are being played by teachers who are co-invested in learning from the rehearsal experience. Simplifying access to emotional data could enable teachers to develop pedagogical empathy and bring it to the more complex spaces of their classrooms.

Our data indicate that rehearsal debriefs can be venues for collecting rich veins of emotional data. NRTs regularly shared how they felt during the rehearsal under particular pedagogical conditions. This enabled all participants to project how actual students might feel under those or imagined conditions. The prevalence of emotional data and its uptake within the debrief discussion motivated us to investigate the potential of debriefs to support the development of pedagogical empathy. We examined eight rehearsal debriefs with in-service teachers to determine how participants generated, considered, and drew implications from emotional data to develop pedagogical empathy. We asked: How were emotional data *made visible* and *used* in rehearsal debriefs?

Method

This study took place within a two-year professional development fellowship for early-career (2nd-7th year) secondary mathematics teachers serving lower-income schools. Participants included 22 high school mathematics teachers from schools across the US. The second summer institute focused on facilitating collaborative group work and culminated in all participants rehearsing this practice, whose debriefs we investigate here. Teachers were randomly assigned to one of two rehearsal rooms. Four rehearsals were conducted in each room (eight total rehearsals), so that each teacher had the opportunity to rehearse once and participate as an NRT three times. After each rehearsal, the teacher educator (TE) prompted the group to debrief the experience, with RTs and NRTs sharing their reflections. While generating and using emotional data is the focus of the current study, it was not a focus of the professional development program, the rehearsal process, or the debrief discussions. We draw on audio and video recordings of the debriefs following each rehearsal. Each was transcribed for analysis.

All RT and NRT talk turns were segmented and coded based on the ways they generated and used data: attending, interpreting (Sherin et al., 2011), or implicating (Baldinger & Munson, 2020). During this process, *interpreting* talk turn segments, in which the speaker moved beyond observable events and offered an internally constructed understanding of them, were sub-coded to identify interpretations which were emotive (e.g., "I felt overwhelmed…"). We then shifted our analytic lens from the talk turn segment level to the *emotion vignette*: a series of one or more talk turn segments in which student emotions (those of NRTs in their position as students in the rehearsal or the projected emotions of real students) were explicitly considered. To identify vignettes, we first contextualized all instances of emotive interpretation. Vignettes were bounded as starting and ending with topic shifts, in which NRT emotions were a component of the topic. In a second pass, we searched for instances in which student emotions were discussed. These instances were similarly contextualized into vignettes.

Memos for each vignette were constructed to record how emotional data arose, the content of the emotional data, and how those data were used, leading to the development of emergent codes. Each vignette was coded, and codes were expanded, collapsed, and added until all vignettes could be represented using the coding scheme. Where emotional data were made visible or used in multiple ways, multiple codes were applied.

Findings

We found 48 vignettes in which RTs, NRTs, and TEs considered student emotions. In no debrief discussion were student emotions absent. Speakers in all roles participated in uncovering and considering student emotions.

How emotional data were made visible in debriefs

Emotional data arose in the debrief discussions in four ways: (1) requests for emotional data, (2) offers of emotional data from NRTs, (3) noticing of NRTs' emotional responses, and (4) drawing implications from emotional data that had been made public. Thirty vignettes included more than one code. For instance, a vignette might include a request for emotional data by an RT followed by an offer of that data from an NRT.

Requests for emotional data occurred when an RT or TE asked NRTs in their role as students to report their own emotional responses to the rehearsal. Thirteen of the vignettes included a request, often at the beginning of the rehearsal debrief when RTs framed what they hoped to learn from NRTs. For instance, an RT opened a debrief by making a request for emotional data, saying, "For me I think it would be helpful to know, when we did come over and confer, what was useful? What was obstructive? How did that feel?" The RT explicitly elicited NRTs' emotional experiences, indicating that such data would be useful feedback on their pedagogical decisions.

NRTs *offered emotional data* when they reported emotions they experienced as students during the rehearsal. These emotional interpretations of the rehearsal were one of the primary ways emotional data surfaced, occurring in 30 of the 48 vignettes. NRTs reported a wide range of emotions, including anxiety, security, confusion, excitement, and pleasure. These offers were typically highly-specified to the conditions in which the emotions arose. For instance, one NRT reported on their emotional response to an interaction with an RT, saying, “When you [RT] were like, ‘I’m gonna walk away and I’m gonna come back and check in on you.’ That was when I felt like I could breathe and go, ‘Okay, wait. What did I not get?’ So I had a moment of tension when I felt like you were quizzing me and I was like, ‘I really don’t know.’” The NRT described a complex emotional situation, with confusion about the mathematical work, anxiety from being quizzed, and then a sense of relief when the RT gave the NRT time to think. Emotional data were often embedded in the retelling of salient events, and those events were often salient precisely because they generated an emotional response.

Noticing emotional data occurred when any participant identified an emotion that they inferred was experienced by an NRT during the rehearsal; emotional data arose this way in 9 vignettes. For instance, one RT pointed out a moment that caused him to think about his pedagogical choices during the rehearsal, saying, “There was one situation where I saw two people talking and then there was one person kinda left out. And I was trying to think like, maybe it was a strategic move that the group did, or maybe it was just because of the nature of the problem. Like, they’re just so excited and someone got left out.” In nearly half of these instances (4 of 9), noticing emotional data was coupled with a request for additional emotional data.

Emotional data surfaced when any participant *drew implications related to emotional data* that extended beyond the rehearsal events (33 of the 48 vignettes). In these instances, the speaker(s) built on previously offered emotional data to consider on how those data might inform their thinking about teaching and learning. For instance, in a vignette in which speakers discussed the “quiet anxiety” felt during a rehearsal, one NRT mentioned that in his own teaching he had thought about asking students in similar moments, “What is hard about this task?” but he never had. Now, in reflection, he stated that, “If somebody would’ve asked me that, I’d be like, ‘Okay. So this is hard. I don’t get that. This is confusing.’ Like, it would’ve given me that sigh of relief to be able to say that.” The emotion of relief described here is a projected one, rather than one felt in the actual rehearsal.

How emotional data were used in debriefs

Emotional data that surfaced in the debriefs were used to inform teachers’ sensemaking of the rehearsal and, often, classroom practice more generally. We identified six ways emotional data were used by participants: (1) providing feedback to RTs, (2) contrasting emotional interpretations, (3) connecting instances of shared emotions, (4) projecting student emotions, (5) examining teacher decision-making, and (6) drawing implications for classroom practice. Vignettes often included multiple uses, supporting robust understandings of pedagogy.

The most prevalent function of emotional data (34 of the 48 vignettes) was for NRTs to *provide feedback* to the RTs. NRTs used emotional data to address RTs’ questions or to provide information about the function of RTs’ instructional decisions. Emotional data were thus viewed as a relevant lens for interpreting the impact of pedagogical decisions. For example, one NRT shared that she felt left out when everyone in her group was recognized except her. The RT took up this feedback, saying “I’m glad I got the chance to experience that now and not with my students, because that could burn a bridge pretty quickly.” NRTs and RTs viewed emotional data as a valid form of feedback on the consequences of pedagogical choices.

In 23 vignettes, participants used emotional data to provide *contrasting emotional responses* to the same event. For instance, one NRT reported feeling excited by a structure that felt “like a race”, while others indicated that this same situation induced anxiety because of the language used by the RTs in the rehearsal. These moments illustrated how different emotional responses are possible to the same situation. In this way, pedagogical decisions could be viewed as creating complex emotional terrain, rather than just positive or negative responses.

A small number of vignettes (2 of 48) included moments where the sharing of emotional data triggered another NRT to offer a different event in which they felt the same emotion. In these instances of *connecting emotional data*, what was common was the emotional response. Participants sought to make connections between the pedagogical choices that generated similar emotional experiences. For example, during a discussion about checkpoints, an NRT expressed anxiety and security, saying “I felt really pushed [...]. As much as I know this content, I still was pushed and I still learned.” Another NRT picked up this idea, saying, “To build off that, I felt I was pushed by each one of you,” and gave an example of the kind of question that pushed their thinking.

In 14 of 48 vignettes, emotional data were used to *project student emotions* – to hypothesize how students in the classroom might feel under particular pedagogical conditions. These included instances in which the speakers anticipated that students might and might not feel the same way an NRT did during the rehearsal. For instance, one NRT shared how she felt supported when the RT checked on her after she had gotten distracted. She went on to project that “the student might feel overwhelmed in that moment.” In these vignettes, participants attempted to leverage the emotional experience of the rehearsal to predict, anticipate, and understand their students’ emotional experiences of pedagogy.

RTs followed up on emotional data in 8 vignettes to *examine their decision-making* process during the rehearsal. For instance, after two NRTs offered interpretations of a teacher move, the RT shared, “Can I comment on my intention? It's just, I wanted to connect with you guys as humans. I just wanted to make sure you felt safe. […] But like, you're right. I should've waited for maybe a more appropriate time to…build that connection or that trust with you." The RT made her thought process in the moment visible, connecting the intent directly to student emotion – in this case security – and then reconsiders how best to implement that pedagogical move.

One critical use of emotional data (27 of 48 vignettes) was to consider how that data might inform decision-making in the classroom. In these vignettes, speakers *drew implications for classroom practice* by suggesting ways to adapt pedagogical moves used in the rehearsal, describing general principles for teaching and learning that they extracted form the experience, or reconsidering their own previous pedagogical choices. In each of these cases, implications were offered directly in response to emotional data, showing how an understanding of student emotions could be used to influence future teacher decision-making.

Discussion

To develop pedagogical empathy, teachers must first recognize that pedagogical situations generate emotions among students, a recognition evident in our data through the repeated requests for emotional data. Moreover, NRTs offered to make their own emotional reactions to the pedagogy they experienced in the rehearsal public both in response to specific requests and spontaneously. Projecting student emotions, drawing implications for the classroom, and examining teacher decision-making all contributed to participants developing understanding of how student emotions might influence learning opportunities and mathematical identities, which NRTs could articulate in a way that students themselves may not. Contrasting or connected emotional experiences generated a nuanced impression of the emotional terrain of the classroom, where individual decisions could have differential impacts on students. Not all of these emotional responses were intended, as several RTs stated, and participants discussed intent and the emotional consequences side-by-side. As RTs tried out new pedagogical techniques as part of the rehearsal, the discussion of student emotional responses fed considerations of how to refine these practices for use in the classroom. NRTs were positioned to name both what they felt and to suggest alternatives that could mitigate negative emotions or elevate positive ones.

While NRTs were a particularly fruitful source of emotional data during rehearsal debriefs, teachers' need for emotional data did not end with the rehearsals. We identified several instances where participants considered how they might elicit similar data from their own students. This suggests that participants were developing the capacity to actively collect emotional data in their own classrooms as an ongoing practice.

This study demonstrates the nuanced ways in which teachers developed pedagogical empathy during debriefs. Just as teachers seek to learn how to respond to emergent student thinking, the teachers in this study actively sought to develop ways of responding to emergent student emotions. The development of pedagogical empathy thus coincides with and acts in support of the development of adaptive expertise.

Discourse Patterns and Collective Cognitive Responsibility in Collaborative Problem-Solving

Jun Oshima, Shotaro Yamashita, Ritsuko Oshima

Shizuoka University

Abstract: In knowledge building, learners achieve collective cognitive responsibility (CCR) by exerting their shared epistemic agency. Although CCR has been discussed as a critical part of the learning process, few studies have established analytical frameworks to examine how learners develop CCR through collaborative discourse. This study analyzed the collaborative discourse of seven groups of three university students each, who were tasked with solving a Jasper Woodbury problem to determine how CCR took shape. It used a mixed-method approach. Its results indicated that there are three distinct discourse patterns related to CCR: (1) collective CCR, in which each group member engaged in discourse, (2) rotating leadership CCR, in which pairs of members flexibly engaged in discourse, and (3) fixed leadership CCR, in which a specific pair of group members led discursive activity. The study concludes by discussing which of these discourse patterns might help students develop and sustain CCR in collaborative problem-solving.

Background and research purpose

In knowledge building, learners are encouraged to collectively advance their knowledge and continuously improve their ideas through collaborative inquiry (Bereiter, 2002; Paavola & Hakkarainen, 2005). Scardamalia (2002) described individual learners' intention to contribute to collective knowledge advancement as their epistemic agency and described collective intentions to do so as collective cognitive responsibility (CCR). As discussed in other studies (e.g., Chen et al., 2015; Damşa et al., 2010; Zhang et al., 2009), learners' epistemic agency should be exerted through their responsibility to construct collective ideas by making a judgment of the promisingness of their ideas and further improving them for solving their authentic problems.

Because knowledge building is a collaborative activity, it is challenging to evaluate knowledge building practices and processes. Several researchers have suggested that we must analyze how learners represent their collective knowledge and how these representations change over time in order to appropriately evaluate its advancement (Oshima et al., 2012; Scardamalia et al., 2012). Studies have attempted to develop methods of evaluating these representations. For instance, Zhang et al. (2019) suggested using idea thread mapping diagrams, which allow learners and instructors alike to assess learners' contributions to collective knowledge building over time in a network graph. Oshima et al. (2012) suggested using Knowledge Building Discourse Explorer (KBDeX) which provides learners with a vocabulary network and helps them ascertain which of their ideas are or are not connected. Other tools, such as Feng et al.'s (2019) idea-friend map (which was developed from KBDeX) helps students determine how their ideas are connected and how they can further integrate or elaborate upon their ideas.

Although previous studies have examined how collaboration between or within communities helps improve ideas, few studies have examined how individual learners contribute to collective knowledge advancement in CCR. Gutiérrez-Braojos et al. (2019) used scientometric analysis to assess the relationship between individual contributions and CCR. In their study, university students evaluated how the notes of their peers contributed to collective knowledge advancement. Each student's contribution value was calculated as the proportion of their notes which their peers recognized as helpful. While this approach allows us to represent CCR within a community and identify different types or values of contributions, it does not analyze how this process helps students improve their ideas. This study, therefore, aims to propose another analytical framework of CCR by extending socio-semantic network analyses (SSNA) of idea improvement so that both the idea improvement process and the degree of CCR exerted during this process can be evaluated. Below, we propose a new algorithm to represent CCR and demonstrate their analytical framework by examining discourse datasets from seven groups of three university students each.

Method

Participants and setting

The study's participants were 21 university students (seven groups of three). Groups of three participants were asked to solve a Jasper Woodbury problem called "Rescue at Boones Meadow (CTGV, 1992)." In the problem, a protagonist named Emily must bring a wounded bald eagle back to an animal hospital using a small airplane. Participants were asked to find the fastest route from the meadow to the hospital. The problem was presented in a 15-minute video and they were given 45 minutes to engage in collaborative problem-solving. They were also provided with an iPad (to watch the video) and a whiteboard (to write/draw their ideas). Their conversations and actions were recorded on video.

Analysis

The participants' conversations were transcribed verbatim and then subjected to two analyses. First, we modified and extended the original SSNA algorithm of KBDeX in order to analyze study participants' idea improvement and CCR. The original algorithm represents idea improvement as the aggregate change in the total degree-centrality (DC) of words in a given network, taking each turn in conversation as a unit of analysis. In the modified algorithm, we used the moving stanza-window method (Siebert-Evenstone et al., 2017) to conduct further analysis. Because every conversational turn is influenced by the previous turn and influences the next turn (Wells, 1999), we set a stanza-window of three conversation turns as a unit of analysis and then calculated the cooccurrences of words in all transcribed interactions. By modifying the algorithm, we made it possible to detect which conversational turns elicited ideas represented in other conversational turns, and thus made it possible to detect the origins and trajectory of idea improvement.

Second, we calculated each participant's idea improvement process by analyzing a discourse subset from each participant. We then compared each participant's contribution with their group idea improvement as well as all other students' contributions in order to evaluate how each participant contributed to idea improvement. After identifying various types of CCR, we conducted a discourse analysis of segments which SSNA identified as critical for examining discourse patterns.

Results

Idea improvement and CCR

For evaluating group idea improvement as well as individual contribution to it, our modified algorithm visualized the improvement processes as seen in Figure 1. The vertical axis represents the total value of the degree centralities in the word network. The steep increase in the graph means a pivotal point in discourse for improving ideas. In each group, we visualized four different lines representing the group as whole and three individual contributions. Through visual inspection, three types of CCR were identified: (1) *collective* CCR (two of the seven groups), (2) *rotating leadership* CCR (one group), and (3) *fixed leadership* (four groups). In the *collective* CCR groups, all three participants contributed equally to idea improvement at the group level (see the left graph in Figure 1). Participants' patterns of change in the total DC were similar to one another as well as the group improvement. In the *rotating leadership* CCR group, pairs of participants led CCR and the configurations of these pairs changed over time – i.e., each participant contributed to the group's idea improvement at different points in time (see the shaded areas on the right side of Figure 1). By contrast, a specific pair of students led discourse in the *fixed leadership* CCR groups.

Discourse patterns and CCR

Here, we examine segments of a collective and a rotating leadership group's discourse in order to identify patterns of discourse by which students held their CCR. These segments were selected because the collective CCR group displayed a remarkable increase in total DC and because different pairs of students were responsible for the rotating leadership CCR group's increase in DC.

S, J, and I's collaborative discourse is presented as an example of a collective CCR group. The following is a segment of their conversation turns 562–567:

562: S: OK, I got it. [Larry and Emily are in the same town.]

563: J: It doesn't matter if we go to the gas station and come back to the town by car, does it?

564: S: Well, see...

565: I: You mean that Larry will drive a car [to the gas station] while Emily flies [to the wounded eagle's location]?

566: J: Yeah, Larry drives a car!

567: I: On the highway.

This discourse pattern reveals that I and J built on S's understanding that two characters Larry and Emily were in the same town. S's understanding helped the other participants consider a new solution to the problem. By taking turns in conversation, they shifted leadership around to different configurations of pairs (S–J, S–I, and I–J).

Y, K, and M's collaborative discourse is presented as an example of a rotating leadership group. The following is a segment from their conversation:

390: Y: We consume 40 gallons [of gas] from here [the town] to there [the wounded eagle's location].
391: K: And, we can only use the road from the gas station to the town.
392: K: Our problem is – how can we bring the eagle back to Boones Meadow... No, from Boones Meadow back to the town.
393: Y: We have to go back to here [pointing to the town on their whiteboard map].
394: K: We have to think of the route to bring the eagle back from Boones Meadow to the town.
395: Y: No, no. We have to start from the town then go back to the town.
396: K: Oh, we have to think of the round trip!

In the other selected segment (633–638), another pair, Y and M, engaged in discourse in the similar way. Thus, the rotating leadership group distributed their collaborative leadership in different configurations of pairs over time to advance their collective knowledge.

633: M: As a different idea, we can say, Emily flies to Boones Meadow [the place of the wounded eagle] then takes another flight to the gas station. But, she does not have enough [gas], so she must walk to the station after landing on the way [to the gas station]. After Emily gets to the station, Larry brings the eagle back to the hospital in his car.

634: Y: What did you say after Emily gets the gas station?

635: M: Well, Emily flies from here [pointing the town on their map on the whiteboard] to here [pointing Boones Meadow on their map on the whiteboard], right? She still needs to move five miles [from Boones Meadow to the gas station].

636: M: While Emily flies to Boones Meadow, Larry can drive to the gas station. He waits for Emily's coming with the eagle from Boones Meadow. He then brings the eagle back to the town in his car. Isn't it the fastest route?

637: Y: But, we are not quite sure if she [Emily] can land on the way from Boones Meadow to the gas station, are we?

638: M: Yeah, you're right. Not sure about it.

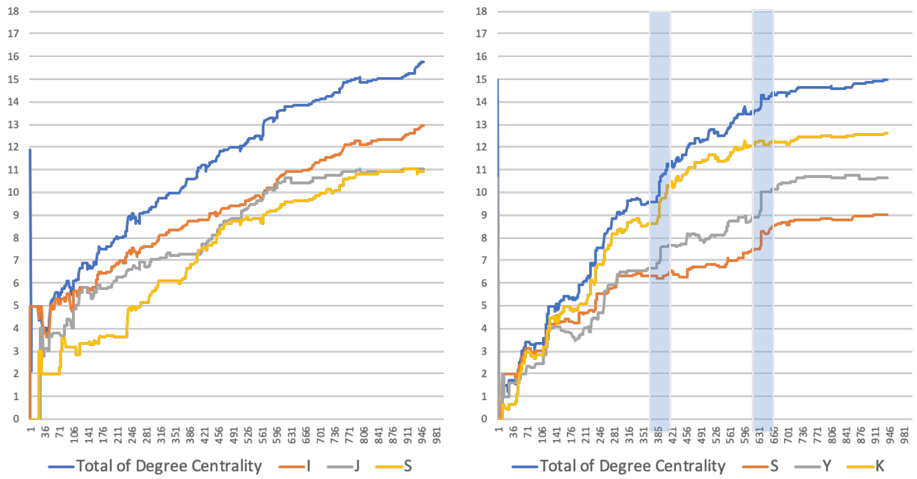

Figure 1. Temporal change in the total degree-centralities over conversation turns in a collective CCR group (left) and a rotating leadership CCR group (right).

Discussion

First, our study's modified SSNA algorithm articulated how students in a group engaged in CCR through collaborative discourse by identifying three modes of CCR. We expected that most participants would exhibit collective CCR. However, only two groups exhibited this pattern. The majority of groups exhibited a fixed leadership mode of CCR. All study participants were engaged in CCR throughout the idea improvement process. Although Ma et al. (2016) reported a similar finding at the individual level, this study expands their findings to collective knowledge advancement.

Second, this study revealed critical differences in the discourse patterns of each of the three modes of groups identified above. In the collective CCR group, different pairs took conversational turns smoothly within the same sequence of conversation turns and performed as a whole. Such smooth changes did not occur over a single sequence but over multiple sequences in the rotating leadership CCR group. Both discourse patterns helped the participants attain CCR as a group. Of course, different discourse patterns are appropriate for different contexts and group cultures.

Conclusion

This study examined CCR in collaborative problem-solving through a mixed-method approach. It identified different patterns of CCR and examined how study participants engaged in CCR through collaborative discourse. It found that that students attained CCR by sharing or rotating leadership of small groups. Future studies should examine individual-level factors which influence CCR or which discourse patterns should be encouraged to help fixed leadership groups transcend their current practices.

Instructional Design, Situational Interest, and User Experience: Applications of Learning Experience Design to Promote Children's Online Engagement

Joseph Wong, Natalie Au Yeung, Bella Lerner, Lindsey Richland
joseph.wong@uci.edu, natalie.auyeung@uci.edu, lerneri@uci.edu, l.richland@uci.edu
University of California, Irvine

Abstract: Historically, learning for young students has occurred in formal, in-person classroom environments. But in just a matter of weeks, children were mandated to transition to a completely new mode of learning, facing new learning challenges with heightened anxieties. To this end, we aim to better understand how our learning experience design (LXD) efforts support or hinder children's engagement while participating in an online, video-based math course. This study operationalized LXD through the integration of e-learning instructional design (ID) as a lever for promoting students' situational interest (SI), emphasis on human-centered design to support students' user experience (UX), and the combination of SI and UX to foster student engagement in an online environment. Results provide practical implications for how we can intentionally iterate our designs to sustain children's online engagement as we prepare for future instances of traditional, online and even hybrid models of instruction.

Introduction and theoretical approach towards learning experience design

Currently, one major concern with distance learning is how to best engage and sustain young students' participation throughout the learning experience, given the contextual challenges such as the heightened anxieties caused by the COVID-19 pandemic and the often relatively unsupervised home educational settings (Agarwal & Kaushik, 2020). In this paper, we define engagement as the attention, curiosity, and interest students exhibit during an online video-based math lesson. We then explore how our design choices as researchers, designers and practitioners might support young students' engagement by applying principles of learning experience design (LXD). LXD is the process of creating learning environments to foster learning in a human-centered, goal-orientated method (Floor, 2018; Correia, 2018). In the context of our study, we operationalized LXD by grounding our course in e-learning instructional design (ID) frameworks and ensuring quality user experience (UX) design. We also explored the connection of a third facet: students' situational interest (SI) within a learning environment, as a motivator for sustaining their online engagement. Through this process, we leverage quality ID to support students' SI, strong UX to alleviate technical difficulties related to distance learning, and the combination of the two to facilitate increased engagement. These results provide practical implications for how we can intentionally iterate our designs to sustain young students' online math engagement.

Research in online learning attributes increased student engagement to quality ID (Pappas, 2015), student UX with the interface (Hu, 2008), and student motivational factors (e.g. interest, self-efficacy) that can emerge as a result of the learning environment (Chen et al; Sun et al, 2012). Centered around the notion that "learning" is inseparable from "doing," we adopted the Situated Cognition Theory (SCT) framework so that learners could grasp the concepts and skills that are taught in the context in which they will be utilized (Brown et al., 1989). In practice, SCT emphasizes immersive learning environments, where new information is taught to learners in a way that simulates real-life settings. We operationalized this by using pre-recorded videos of a real-world math lesson being taught by a teacher to students in a real classroom, and embedding interactive opportunities for modeling, coaching, scaffolding, articulation, reflection, and exploration (Pappas, 2015). Leveraging the SCT framework for e-learning course design, we assess students' SI as a result of our ID efforts. Situational interest refers "to the interest activated by the immediate learning environment" or the interest given the novelty aspect of a learning task (Schraw & Lehman, 2001). Past research indicates that SI is a powerful motivator in areas of math, reading, and history, when learner participation and interaction throughout the entire learning process is sustained (Chen et al, 2001). Thus, this study allows us to better understand how our intentional design choices within the online learning environment influence young students' SI to foster online engagement. Lastly, we explore students' UX, as it is considered a key contributor to students' success in online learning environments and has been shown to increase student engagement (Pellas, 2014). A common approach to assess UX in online courses is to measure course usability (Hu, 2008). In an online course, usability refers to the effectiveness of the learning interface and whether or not a student can successfully interact with the course platform to accomplish an intended task. As such, course usability aims to create a positive student UX through content accessibility, a significant predictor of student engagement in online learning environments (Thomson & Lynch, 2003).

To this end, we aim to better understand how our LXD efforts support or hinder young students' engagement while participating in an online, video-based math lesson. This study is guided by the following research questions: (RQ 1) *To what extent do students' SI within an online course influence students' perceived learning engagement (PLE) in math while learning remotely during a worldwide pandemic?* (RQ 2) *To what extent do students' course usability within an online course influence students' PLE in math while learning remotely?* (RQ 3) *Did the ID and course usability support students' online learning experience?*

Methodology

Course design context

The online course modules were hosted on a researcher-designed e-learning platform that was integrated with the teachers' preferred learning management system (LMS) to minimize course flow disruption. Cognizant of the research behind effective UX and ID in self-paced courses, intentional design choices were made to maximize digital interactivity and learner engagement. More specifically, an hour-long video lesson was segmented into ten parts instead of one long continuous stream to reduce fatigue, cognitive load, and opportunities for students to mind-wander (Mayer, 2019). Scaffolded problem sets (worked examples) were placed in between video segments for students to practice problems immediately. These types of problems scaffold novice learners by drawing attention to the structural similarities in the lesson to ensure students attend to the key ideas, concepts, and relationships in practice (Begolli & Richland, 2018). For example, students were first asked to recall strategies they learned from watching the videos. Next, students plugged in the procedural steps to solve the math question. Then, students were asked to compare their procedural steps with model example strategy solutions. After making comparisons across problem types and strategies, students would solve the math problem by assessing their conceptual understanding. Lastly, solution reflections were embedded within each problem scaffold for students to explain, in their own words, how they solved each math problem with their chosen solution strategies. This design choice enabled students to actively engage in their own productive metacognitive judgments and reflect on "how and why" they arrived at their solutions, which has been found to foster learner responsibility, increased test preparation, and review and practice (Tullis & Benjamin, 2011). Careful considerations were made to ensure that the course interface facilitated quality UX design. For example, course roadmaps, course goals, and navigational instructions were clearly "highlighted" and "boxed in" to promote learner ease of use and findability. Additionally, standardized vector icons were utilized before every instructional type, allowing students to differentiate between interface instructions as opposed to lesson-specific instructions. Each video also had instructions clearly stating how to pause, play, and re-watch. These UX design choices were made to mitigate visual complexities, technical difficulties, and allow users to focus on the content most relevant for the task at hand. The ability to click backwards in the course enabled students to freely navigate the course space with more autonomy. Through these iterations, an array of design decisions grounded in LXD principles were implemented to co-develop this online video math course, with the goal of integrating elements of a real classroom and interactive features of an online learning environment in order to maximize students' online engagement.

Data collection and analysis

We recruited 5th and 6th grade teachers from two districts in Orange County. A total of three 5th grade teachers, six 6th grade teachers, and one 5th/6th grade combo-class teacher agreed to be a part of the study. There were a total of 12 classes, each with 26-33 students. Of the (N = 195) students who participated, 55.8% identified as female and 44.2% identified as male. Student ages ranged from 10 to 13 years old, with a majority being age 11 (46%) and age 12 (44.9%). This sample consisted of children from a variety of racial/ethnic backgrounds (31.9% White, 2.7% Black, 22.1% Asian, 21.2% Latinx, 22.1% other). The online math lesson was administered to all students during Part 1 of the study. Two days later, four questionnaires were administered to students during Part 2 of the study. This included adapted versions of the Situational Interest Scale (Chen et al., 2001) and the Standardized User Experience Percentile Rank Questionnaire (SUPR-Q; Sauro, 2015). Both measures were 5-point Likert Scales ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). Students' PLE was also measured using an adapted 5-point Likert scale (Rossing et al., 2012). Lastly, we used an adapted version of the Children's Impact of Events Scale (CRIES) developed by the Children and War Foundation (2005), which was a 4-point Likert scale, ranging from 1 (*not at all*) to 4 (*often*). Quantitative data were analyzed using SPSS. Pearson correlations tested the associations between the key variables in our study. Multiple regression analyses were conducted to examine how students' online usability, as well as students' SI, would influence their PLE in math while learning remotely. The SUPR-Q and SI scores were used as predictors on the outcome variable (PLE) to examine research questions one and two, respectively. Students' CRIES score was included in the regression model as the control variable. Qualitative analysis of student evaluation responses were analyzed in Qualtrics

Core XM, which was deductively coded. A codebook was defined and systematically applied. Inclusive and exclusive statements were clearly written to differentiate code applications.

Findings

Descriptive statistics were measured (PLE, SI, CRIES, and SUPR-Q scores). All of the measures were reliable based on the widely accepted recommendation of a Cronbach's alpha of .70 (Nunnally, 1978). Pearson correlations indicated that there was a significant positive moderate correlation between SI and students' PLE ($r = .67$, $p < .001$). Similar significantly positive moderate associations were observed between SI and students' online course usability ($r = .63$, $p < .001$), as well as between students' PLE and students' online course usability ($r = .59$, $p < .001$). However, there was a significantly low and negative association between students' levels of anxiety during the pandemic (CRIES) and their PLE ($r = -.22$, $p < .01$). A similar association between students' levels of anxiety and students' course usability was observed ($r = -.16$, $p < .05$). To estimate the effect of students' SI on their PLE in online math during the pandemic, multiple regressions were conducted with the PLE score as the outcome variable (see Table 1). Results indicate that there is a significant main effect of students' SI score ($\beta = .59$, $p < .001$). In addition, results indicate that there is a significant main effect of students' online course usability score ($\beta = .34$, $p < .001$). On average, students' online course usability and SI explained 51.5% of the variance in the model $F(3, 191) = 67.7$, $p < .001$.

Table 1: Multiple regression with SI and SUPR-Q as predictors for PLE, with CRIES as a control variable.

	Perceived Engagement	
Predictors	β	*SE*
SI	.589***	.078
SUPR-Q	.342***	.086
CRIES	-.108***	-.141
(Constant)	.056	.292
R^2	.515	
N	195	
Note: *** $p < .001$; ** $p < .01$; * $p < .05$ (Two-tailed test).		

There were two main themes identified that were related to the effectiveness of our ID and course usability. The first theme was "instructional design enhanced students' engagement," and the second theme was "the usability of the online course influenced students' learning experience."

Theme 1: Instructional design enhanced students' engagement

Students' engagement was defined as the amount of active participation, motivation, effort, interest, and attention while interacting with the online course. Through our analysis, we noticed emerging patterns specifically related to the implementation of the SCT instructional design model. This model used pre-recorded video to situate students in a real-life classroom context to support students' online engagement. For example, many students expressed that the design of the video lesson made them more motivated and willing to spend more time and effort learning online.

Student A: "…I like the interactive ways that I'm able to learn on this [online course] activity as "…it [online course] makes me feel like the real classroom…"

Student B: "I liked how this [online course] activity had videos and felt like you were really learning in class. It was easy and useful. This [online course] activity was also very easy to understand and helped me to understand there are many ways to solve a problem."

Student C: "…it [online course] made me want to learn even more… also I like how they [online course] use videos to explain the lesson and that help me a lot."

Theme 2: The usability of the online course influenced students' learning experience

Students' online course evaluations provided evidence on how our course's usability supported students' UX within the online learning environment. These excerpts provide evidence on how our conscious efforts to a more human-centered design affected students' learning experience. Self-paced learning was defined as references to autonomy, on your own time, and time frames with regards to pacing while participating in the online course. For example, they could easily navigate using the back button within the course interface. Additionally, students were able to re-watch, pause, and play a video if they did not grasp the concepts or explanations the first time.

Student D: "What I liked about this learning activity [online course] is that its a video and if I don't understand something I can go back to the point I don't understand"

Student E: "I liked that I could go back and see what I either did wrong or right."

Student F: **"**I like how I can go on my own pace and replay the lesson if I need to."

Conclusion and implications

This study operationalized LXD through the combination of e-learning ID as a lever for promoting students' SI, emphasis on human-centered design to support students' UX, and the combination of SI and UX to foster student engagement. Interestingly, our analyses indicate that students' SI and UX while interacting with the online learning interface were significant predictors of students' online engagement, even after controlling for students' heightened anxieties due to the global pandemic. Snippets of student responses reveal that the use of video situated in the real classroom context may be motivating students. We deduce that students' SIs are increased as a direct result of implementing the SCT instructional design framework. When participating in the online course, students felt like they were in a real classroom and mentioned how watching real students and teachers increased their motivation to learn even more. By preserving the ecological validity of the classroom environment, students were able to follow along with the teacher and immediately practice the math concepts. Gleaning student commentaries also revealed that careful attention to the course usability promoted quality UX design by facilitating ease of use, findability, and navigability (Simunich et al., 2015). These UX design decisions afforded students the opportunity to recognize their initial understandings of the math concepts and allow students to review and practice by navigating backwards or replaying a video. As such, students were able to take control of their learning pace and adapt their learning behaviors to stay engaged in the course content. Thus, the simultaneous integration of ID and UX design may be consequential in supporting students' engagement in an online learning environment. While more research is certainly warranted, we also conjecture that the underlying mechanism linking LXD and engagement is likely to be the resulting effect of increasing student's self-efficacy, task-value, and self-regulation. In conclusion, this study supports the literature on student online engagement and students' learning experiences through empathy, informing LX designers and practitioners on how we might effectively co-design and iteratively improve teaching and learning for future instances of traditional, online and even hybrid models of instruction.

Feedback in the Wild: Discrepancies between Academics' and Students' Views on the Intended Purpose and Desired Type of Feedback

Martin Van Boekel, Shelby Weisen, Ashley Hufnagle
vanbo024@umn.edu, weise207@umn.edu, hufna011@umn.edu
University of Minnesota

Abstract: Getting feedback on assignments is as ubiquitous of an educational experience as anything. The goal of feedback is to move students from where their skills and knowledge currently lie to some end criteria identified by the instructor. The present study highlights the gap between theory and practice by comparing undergraduate students' views on the purposes and idealized content of feedback to those of academics. The results suggest a shared understanding of the purpose of feedback. However, students do not necessarily *want* feedback that reflects those purposes. The relationship between students' views on feedback and their actual experiences with feedback are briefly discussed, as are the implications of the findings.

Keywords: Feedback, Motivation, Learning Outcomes, Teaching

Introduction

Throughout our time in school, we receive feedback on almost everything we do. But do we really have a universally accepted idea of what feedback and its purpose is? The primary goal of academic feedback, as generally understood by researchers, is to move students from where their skills and knowledge currently lie to some end criteria identified by the instructor (Hattie & Timperley, 2007). In their systematic review of the literature, Hattie and Timperley (2007) identified four main types of feedback students can receive: *Task Feedback, Process Feedback, Self-Regulation Feedback, and Praise/Self Feedback* (See Table 1 for representative examples of each of these four types of feedback).

Task Feedback is surface-level feedback that provides students with task specific feedback about whether their work is correct or incorrect. *Process Feedback* directs students to general strategies that may be applied to both the current task and future tasks. Because process feedback is more generalizable and encourages deeper learning, it is more beneficial and longer term than task feedback. Arguably, the most beneficial type of feedback is *Self-Regulation Feedback.* This type of feedback instructs students on how to self-assess their work and develop the skills necessary to become better self-regulators. *Praise/Self Feedback* is vague and more focused on the student than the task. Praise alone can have ironic consequences for future motivation because it does not encourage students to invest further effort. Thus, it tends to be the least effective at improving academic performance.

Contemporary feedback research has made important progress in illuminating factors that may impact an individual's response and, consequently, their uptake and use of academic feedback. Pekrun and colleagues (2014) observed the way feedback is formatted will impact a person's emotional reaction to that feedback (e.g., self-referential versus norm-referenced). Additionally, an individual's personality traits are likely to influence how they respond to feedback; although, generally all personality types tend to lose motivation when faced with negative feedback compared to positive feedback (Swift & Peterson, 2018). Finally, negative feedback can undermine our memory (Reeve et al., 2014) and consequently, our ability to put into action a plan to use that feedback may be impeded.

While we have an ever-growing understanding of the factors that impact our uptake and use of feedback, we know very little about feedback in naturalistic learning environments. Understanding feedback "in the wild," or how students think about and use feedback in a classroom setting, is critical for understanding the generalizability of past research. As an important first step in highlighting the gap between theory and practice, *the present study examines undergraduate students' definitions of academic feedback and their preferred content/type of feedback to receive.*

Methods

Participants

The present study was conducted in a first-year introductory applied psychology college course. The class had an enrollment of 102 students, 80 of whom consented to participate in the study (M_{age}=18.98, SD=1.36). The data presented came from a larger, IRB approved study that examined students' memory for feedback in a naturalistic classroom setting. For the purposes of the present study, we present student responses from two open-ended questions from the survey portion of the study: *What is the purpose of academic feedback?* and *Describe the content/focus of your desired feedback upon completing an assignment.*

Materials

Codebook

Students' responses to the open-ended questions were broken into thought units. Thought units were defined by a comment that contained one unique idea (see Table 1 for examples of what we classified as one feedback unit). Student thought units were coded into the four feedback categories presented by Hattie and Timperley (2007).

In instances where the thought units could not be placed into one of the four categories, it was assigned as "Other." These were then examined for similarities. No patterns within the "Other" category emerged and therefore remained as one category. The codebook was created and refined by all authors on this paper. The first author of this paper coded the students' responses to both questions.

Results

To best understand how students define the purpose of feedback using the criteria defined by Hattie and Timperley (2007), Table 1 shows the frequency of students' responses to the two open-ended questions. Students overwhelmingly (87.5%) identified *Process Feedback* as the primary purpose of feedback. Thirty-five students (43.75%) noted the importance of *Task Feedback*. Interestingly, no students discussed the Self-Regulatory or Praise/Self nature of feedback in their responses about purpose.

Even though students in their identification of the purpose of feedback neglected a critical component of feedback (i.e. Self-Regulation), most students noted the need for feedback that helps them improve in the learning process (Process Feedback). Hattie and Timperley (2007) noted that *Process Feedback* and *Self-Regulation Feedback* are key to deeper learning and subsequent subject mastery. Students stated that one of the purposes of feedback is to provide details about whether or not their work is correct, suggestive of the *Task Feedback* category. While task feedback is not as adaptive and generalizable as process feedback, it still has benefits of helping students understand the expectations of the current task. Taken together, we see that students can cite the importance of error-detection and awareness of strategies for producing better work (*Task Feedback* + *Process Feedback*).

While it is important to know that students and academics define the purpose of academic feedback in similar ways, it is also important to understand *whether there is congruence between what the students know is important to be included in feedback (the purpose) and what types of feedback they would actually like to receive.* Although students knew the purpose of feedback is to provide process related information, more students identified that they would want *Task Feedback* on an assignment (see Table 1) than any other type of feedback. This suggests that students may not be thinking about feedback as generalizable outside of the scope of a particular assignment (or its longer-term utility). Even though students knew that the purpose of feedback is not to receive *praise*, 16.25% of the students stated that they would like this sort of information in their feedback. This is important because there is little information about the task in *Praise/Self Feedback*. However, students felt that praise/self feedback would make them feel better about their work and may make the accompanying constructive criticism more palatable.

Notably, students' response to the survey suggests that students and academics discuss and understand the goals *and purpose of academic feedback in the same way. However, students do not necessarily want to receive feedback that reflects those purposes.* Prior research has identified both process and self-regulation focused feedback as key to enhancing students' future success. Students' responses mirrored this, at least for the process feedback, indicating both that they saw process feedback as important and desired this type of feedback on their work. Only one student noted wanting self-regulatory feedback. This is important because it may be a sign that students do not have the language to articulate the desire for more support in learning how to self-assess/regulate, or that they do not see themselves as a key player in revising/improving their own work.

Table 1: Number of instances of feedback type for both open-ended questions and example student responses

	Purpose of Feedback		**Desired Content of Feedback**	
	Number of instances	**Example student response**	**Number of instances**	**Example student response**
Task Feedback	35	"I think that the purpose of academic feedback is to help let you know what is wrong and what is done right. It can let you see your errors."	56	"I want to know what I did correct and what I did wrong"
Process Feedback	70	"I think that the purpose of academic feedback is to grow academically as well as a person. It helps me know what areas I can improve which I think are important for academic success."	49	"I would like to hear what I need to improve on for future assignments but also what I did well to keep that for future assignments too"
Self-Regulation Feedback	0		1	" I would also like to get a rubric grade as provided in the course as it helps make changes"
Praise/Self Feedback	0		13	1. "I expected to receive some motivational comments, for example: good work or excellent." 2. "My ideal feedback would be both positive and negative feedback. Receiving compliments on portions I worked hard on would ease the criticism on portions that the professor did not like."
Other (O)	0		8	"I would much rather have feedback that is direct than sugar coated."
Blank	0		2	

Discussion

Even though most students stated that the purpose of feedback was to provide process feedback, when reflecting on what their ideal feedback would contain, students most frequently endorsed task-focused feedback. This discrepancy highlights a gap between what students know to be important at a conceptual level, what they see as important in the "real world," and what types of feedback they actually want to receive and experience. Future research should examine the utility of training students on how to use feedback and rubrics to see if this will help students recognize and benefit from the more impactful process and self-regulation feedback.

While students did not see praise as a main goal/purpose of feedback, aligning solidly with the research, that did not mean students did not want to receive it. A small, but meaningful (16.25%) group of students expressed a desire for praise. Many of these students suggested that praise may motivate their uptake and use of the more constructive feedback by buffering the negative affect that accompanies this critique of their work. This presents an interesting discrepancy. While praise/self feedback does not have immediate academic implications on the assignment at hand, students still want to receive praise to facilitate/support their motivation. Future research should examine whether or not there is truth to this.

A potential limitation of this study is that students responded to the questions about their beliefs surrounding the purpose of feedback and their desired content/type of feedback after completing a free recall of the feedback they received on a class project one week earlier. It is possible that their recall of feedback biased their response to the relevant purpose and content questions. Students' responses may have been constrained by the type of feedback received on the assignment. For example, if students' feedback was limited to praise and task feedback, would it be possible for them to generate examples of other types of feedback? We can address this limitation directly. As previously mentioned, the data presented was part of a larger study examining students' memory for feedback. Our preliminary investigation into the feedback given to the students illustrates that students received a wealth of feedback, spanning all feedback types (see Table 2, from Weisen et al., 2021).

Table 2: Average number of feedback units given by the teaching assistant per student (preliminary analysis)

	Average Number of Feedback Units	***SD***
Task Feedback	10.29	3.30
Process Feedback	10.71	3.99
Self- Regulation Feedback	1.14	1.07
Praise/Self Feedback	0.57	0.53
Other (O)	1.86	0.69

Overall, the present study demonstrates a somewhat shared view of the purpose of feedback by researchers and students. However, students do not necessarily *want* to receive the type of feedback they know to be important/impactful. From a practical standpoint, if both learners and educators understand the types, importance, and function of feedback in the same way, then everyone involved in the educational experience stands to benefit by being more effective users and providers of feedback. It is important that researchers move beyond simply *highlighting* the gap between theory and practice, as is the case in this paper, towards actually closing this gap. Future research should explore whether teaching students how to better locate, as well as recognize the generalizable nature of self-regulatory and process feedback, have positive impacts on their use of these types of feedback and ultimately their learning.

Representational Fluency of Angle during an Educational Robotics Task

Amber Simpson, Binghamton University, asimpson@binghamton.edu

Abstract: In this study, we examined how a small group of fourth grade students used representational fluency during an educational robotic task situated within a makerspace environment. Specifically, we considered how representational fluency played a role in their mathematical understanding of angle, a concept that is difficult for many students to understand. Results from video data revealed that various representations (e.g., language, gesture, concrete) within the task afforded students the opportunity to communicate more fluently about the concept of *angle*. We argue that attendance to multimodal representations, and the communication that occurs around and between those representations, better supports and reveals mathematical learning in non-formal contexts.

Introduction

Making contexts are increasing worldwide, with the general goal of providing an environment for youth to pursue interest-driven learning. Some of those makerspace efforts focus on supporting mathematical thinking, with an emphasis on providing an opportunity for youth to engage in the doing of and thinking about mathematics in authentic and non-formal ways (e.g., Doorman et al., 2019). However, the shift from formal learning to non-formal learning leads us to both a challenge and an opportunity: how do we identify, support, and evaluate the different forms of learning that take place in makerspaces? Our approach to this question parallels this year's ISLS theme of reflecting on the past and embracing the future, as we use insights gleaned from previous research on formal learning contexts to develop a lens that recognizes and embraces the different forms of mathematical learning that take place in informal makerspaces. In particular, we build upon Moore and colleagues (2013) translation model, Bieda and Nathan's (2009) investigation into representational fluency, and Alibali and Nathan's (2012) emphasis on gesture, to identify how youth engaged in an informal makerspace robotics activity use representational fluency to move between different modalities in their mathematical thinking and communication. In this paper, we investigated the following: What role does representational fluency play in fourth grade students' mathematical thinking of angle during an educational robotics task? This short paper is a mixture of empirical and methodological work, as we share the complex details of our analysis in order to illustrate how our research emerged from both past research and new visions of the future of mathematical learning.

Theoretical grounding

Scholars have argued that bringing computational tools into learning activities can provide multiple pathways for expressing and solving problems (e.g., Papert, 1980). Student's engagement with technology and computational devices is highly valued in STEM activities, and scholars have argued that in such interdisciplinary contexts, representations can support and deepen students' knowledge of STEM content (Korzma, 2003; Nathan et al, 2013; Nathan et al., 2017). Given the multimodal nature of robotics and programming environments, students developing such procedural knowledge require translation across different representations including symbolic, concrete, gesture and speech representations in order to solve problems (e.g., Alibali et al., 2012). However, one challenge students have to overcome as they complete such tasks is to fluently translate between representations. For this work we will use the framework for *building cohesion* across representations in STEM integration activities to understand how students used language, gestures and other forms of representations to ground their mathematical understanding of angles in a multimodal learning environment.

Methods and analysis

The data for this study was collected from the TinkerLab, a makerspace within an intermediate school (i.e., grades 3-5, ages 9-11) located in New York state. We focus here on one group of fourth-grade students (2 females, 3 males) who had experience with making activities as part of their weekly curriculum in the TinkerLab. The making activity was designed specifically to engage youth in the integration of digital tools, computational practices, and mathematical concepts during a free period during the school day. The activity consisted of two unstructured and student-driven phases. Phase 1 required the group to make a path for Dash (a programmable robot) by placing the tape on the floor from one side of the room to the other. This path was to be traversed by another group. Phase 2 required the group to program Dash using Blockly app on iPad to travel on the path that was placed by the other group. Youth were also provided with other tools - a pencil and measuring tape to measure the path. The activity lasted for approximately 22 minutes. Data collected from this group included a standalone camera that captured the group as a whole and two GoPro cameras were worn on the chest of two of the students that captured the point-of-view perspective of those students.

Our data analysis process consists of four phases. First, to sensitize ourselves, research team members silently watched a video in two-minute increments, followed by a discussion on what we observed in that increment (Jordan & Henderson, 1995). Our observations were grounded in evidence from the language, gestures, and actions captured on video. Second, each team member individually wrote descriptive and analytical memos for video data within ~15 sec increments. The flexible nature of the memoing process provided us with a "space and place for exploration and discovery" (Charmaz, 2006, p.81–82) and allowed us to take risks through articulating, exploring, and challenging our interpretations of the data. Third, our individual memos were then placed in a shared excel sheet, along with evidence of what was observed, allowing each member to look within and across memos. Regardless of how inconsequential these thoughts, feelings and impressions may initially seem, creation of a record in the form of memos ensured the preservation of such ideas that may later prove significant (Polit & Beck, 2006). Fourth, these individual memos were then analyzed for how students used representational fluency along six categories (see Table 1), as well as how their mathematical thinking about *angle* evolved and shifted while engaged in an educational robotics task.

Table 1: An Updated Translation Model-Definitions and Study Example

Category	Definitions and Study example
Concrete (CR)	Representation with Concrete Models, such as hands-on models and concrete physical models. Phase 1: *Almond used the tape to illustrate "here"- indicated to be somewhat of transversal to piece laid and "to here" is parallel to piece tape [continuation of zig-zag]*
Pictorial (PT)	Pictorial Representation, such as graphs, 2-D representations of physical models, and diagrams. Phase 2: *Students are using virtual protractor to determine the angle.*
Gesture (G)	Representational Gesture, iconic and metaphoric gestures, such as shows angle via handshape or motion. Phase 1: *Almond used his hand to illustrate "here to here"*
Language (LG)	Language Representation including both spoken and written communication. Phase 1: when designing a section Almond says, *"Are you saying it's like here to here?"*
Realistic (RL)	Representation through realistic, real-world, experienced contexts, or metaphors. Phase 1: *Red: "It is like one of the crazy roads that you see in movies."*

Note: The foundation of the table comes from Moore, Miller, Lesh, Stohlmann, & Kim (2013). We removed the "Symbolic (SB)" category because such a representation was not used in this context, and we added a new category - Gesture (G) – built upon Alibali & Nathan (2012). The given examples are directly from this study.

Insights

In Phase 1, students often used concrete, gesture, and language representations to express their mathematical thinking of angle, but also to negotiate the goal of laying a path from one side of the room to the other. For example, at the beginning, we observed Red lay a strip a tape to form an acute angle with another piece of tape (see Figure 1-A). Red stated, "Maybe like a ten degree angle." Red provided two forms of representations, concrete and language, which indicated why he formed an acute angle. However, the group was uncertain about Dash's mobility to make such a tight angle, and led to various group members' illustrating and negotiating how *angle* was being shaped by their knowledge of Dash. This was initiated through a language representation by Almond: "Can we do a ten degree angle? I don't think Dash can do ten degree angles." The teacher confirmed, again through language, "Dash cannot do like really tight angles." Green suggested they make the angle wider through both verbal (i.e., "a little wider") and gesture (i.e., moved her hands wider; see Figure 1-B) representations. Almond adopted the language of the teacher, "Yeah, really tight angles." As such, Almond's language representation of angle shifted from ten-degree angles to tight angles.

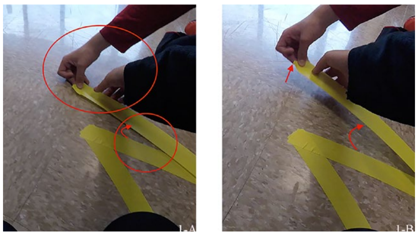

Figure 1-A. “ten-degree angle”

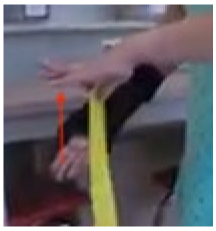

Figure 1-B. “a little wider”

As another example, we observed Pine and Almond communicating through concrete and language representations in regard to adding a piece of tape at a 45-degree angle. Almond was hovering a piece of tape above the floor that would form at a wide angle with the piece of tape already on the floor. Pine stated from a distance, “Make it more complex right there. Make it like a…” Almond rotated the tape with his left arm to form a smaller angle with the piece of tape, providing a response through a concrete representation. Pine confirmed this change in the angle through verbal representation: “Yeah, like a 45-degree angle like that.” This group of fourth graders also illustrated their thinking of angle through “seeing” a zig-zag path through realistic representations. For example, Green noted, "This is starting to look like some crazy shape." “It’s like a machine. It’s like a wire,” stated Almond. Red added, “It is like one of the crazy roads that you see in movies…yeah, there’s like all these different roads.” Students used real-world metaphors (e.g., wire, crazy roads) to express their understanding of zig-zag as alternating left and right turns in the path.

In the shift to Phase 2, with the introduction of Dash and the iPad, we observed a shift in their mathematical language to include the direction Dash would rotate on the path (e.g., “90 degree turn right”). This is likely due to the two kinds of representations afforded by the app as they were required to indicate whether Dash should turn left or turn right to a specific angle by moving an arrow on a virtual protractor (pictorial; see Figure 2).

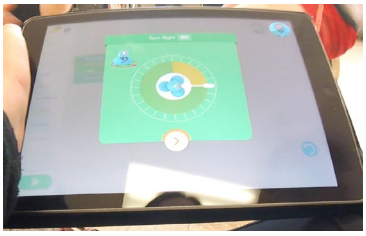

Figure 2. Virtual Protractor

The movement of Dash along the path also provided a space to represent angles through multimodalities both when Dash was not programmed successfully or in planning Dash’s next move along the path. For example, Pine and Almond discussed the angle size and direction in which Dash should be programmed when Almond created a border of the path with his hands (gesture representation; see Figure 3-A), then next placed his body/head over Dash as if he trying to get the perspective of Dash in relation to Dash’s body position on the path (another gesture).

Figure 3-A. Border of the path.

Figure 3-B. “tiny turn”

From his perspective and estimation, Almond stated through language, “So let’s do like 35, 35.” Dash also served as a concrete representation as students were observed manipulating Dash to express their thinking. For example, at the end of a test run, Almond moved Dash as he stated, “We only have to do like a tiny turn” to indicate that Dash was positioned appropriately along the path and a tiny turn was the next line in the code (see Figure 3-B).

Discussion and conclusion

Research on students' understanding of angle has shown their difficulties in coordinating different aspects of the angle concept (e.g., Keiser, 2004; Mitchelmore & White, 2000). The results of this study highlighted how this non-formal learning environment allowed for both everyday and formal mathematical language and mathematical thinking around angle. We recognize that such everyday language (e.g., zig-zag) and ways of representing mathematical thinking (e.g., gestures) may not be as acceptable to the field of mathematics as language-based communication, but we contend that it is evidence of an understanding of quantities and relationships that can be built up into more formal mathematical thinking. We also observed concrete representations afforded by the tools available (e.g., roll of tape, Dash), which are often not tools common to formal learning environments. As a thoughtful reviewer pointed out, further investigation into the role of *perspectives* – particularly as students can take on the perspective of Dash – and how it contributes to their embodied experience is crucial to this work. Further, this group of students seemed to have a shared understanding when using the different angle representations as we did not observe a sense of confusion or misunderstanding through repeated questions or clarifying gestures. Importantly, the addition of gestures as a component of the Moore et al. (2013) model highlight how crucial gesture is to representational fluency as it afforded us additional insights into students thinking of angle than could have been gleaned from any one representation. By adding gesture into their model, we have begun synthesizing their work on representation types with the conceptualization of representational fluency described in Nathan and colleagues' work (Bieda & Nathan, 2009; Nathan et al., 2013, 2017), as well as contributing to the literature on mathematical learning in non-formal makerspaces. Additional research can build upon this empirical and methodological work as the activity and available tools within any non-formal makerspace environment will afford a range of opportunities for students to represent their mathematical thinking and sense-making of other concepts (e.g., linear measurement) across representation types.

Toward a Conceptual Framework for Practical Measurement as Organizational Structure

Eleanor R. Anderson, University of Pittsburgh, eand@pitt.edu
Jennifer Richards, Northwestern University, jrichards@northwestern.edu

Abstract: A growing number of educational improvement efforts are incorporating the development of practical measures of learning into their work. This paper extends previous work on practical measurement by focusing attention on the organizational dynamics of measurement practice. In addition to their role in providing windows to certain kinds of information, measures also function as both carriers and drivers of new and existing assumptions, categories and values. We present the outlines of a conceptual framework of practical measurement situated within processes of organizational persistence and change, and we illustrate key facets of the framework with examples drawn from a DBIR project focused on co-developing practical measures of teacher learning in a university-district partnership.

Keywords: practical measurement, organizational structure, teacher learning

Introduction

Educational improvement efforts are increasingly incorporating the development of practical measures of learning into their work (Yeager et al., 2013), often in ways that situate such measures within ongoing inquiry or continuous improvement processes and position measures primarily as ways to assess whether designs are supporting desired outcomes (Bryk, Gomez, Grunow, & LeMahieu, 2015). Practical measures of learning are intended to be collected without excessive burden, to capture more ecologically valid forms of learning, and to be timely, such that data gleaned from them can be used for formative purposes. Practical measures have been employed extensively in approaches to educational reform drawing on improvement science methods, such as Networked Improvement Communities (e.g., Bryk et al., 2015). There is also growing interest in practical measures among RPPs (e.g., Penuel et al., 2018) and in measures of teacher practice and learning in addition to student learning.

In this paper, we extend previous work on practical measurement by focusing our attention on the organizational dynamics of measurement practice. In addition to their role in providing access to certain kinds of information, measures can also reflect, reify and/or disrupt the assumptions, categories and values at play in a given context (Espeland & Sauder, 2007). These functions of measures are especially relevant for educational leaders as they seek to build on, sustain, and improve professional learning opportunities as part of broader school improvement efforts. In what follows, we describe these varied functions as measurement metaphors and present the outlines of a conceptual framework of practical measurement situated within processes of organizational persistence and change. We illustrate key facets of the framework with examples drawn from a DBIR project focused on co-developing practical measures of teacher learning in a university-district partnership.

Measurement metaphors

Drawing on research in improvement science, sociology and learning sciences, we identity three key metaphors for the roles that measures can serve. We do not see these metaphors as incompatible, but rather as reflecting different aspects of ongoing processes of organizational persistence and change. The relationships between these three metaphors and the functions they represent is shown in Figure 1. We argue that recognizing this wider array of functions is critical for strategizing effectively around school improvement.

Measures as windows

Most discussion of the value of measures of learning—including practical measures—has focused on the information that measurement provides. We refer to this as a window metaphor: Measures allow us to see what learners understand, how schools are functioning, etc. Research grounded in the measures as windows metaphor has shed light on how organizational contexts influence the use of data gleaned through measurement efforts. This includes the organizational routines around data use (Spillane, 2012) and connections between schools and districts in using data (Honig & Venkateswaran, 2012; Simmons, 2012). Yet measures can and do function in other ways as well.

Measures as carriers

Measures are developed within broader organizational and cultural contexts. Decisions about what will be measured and how are influenced by existing structures and norms. Thus, measures can also be understood as carriers: Measures hold the assumptions of particular perspectives within their design and bring those assumptions with them when they are used. For example, law school rankings that reward selectivity carry the assumption that schools that are harder to get into are better (as opposed to, for example, attracting applicants who best match the school's character and mission) (Espeland & Sauder, 2007).

Measures as drivers

Additionally, measures necessarily capture particular slices of the world, foregrounding some features and backgrounding others. As such they serve to focus attention—and action—in patterned ways (Colyvas, 2012; Espeland & Stevens, 2008). While the windows metaphor suggests more of a passive and neutral role, measures can also be seen as drivers: Measures activate the categories, assumptions and values they carry, thus reproducing or disrupting associated patterns of action (Anderson & Colyvas, Under Review). For example, measurement systems organized around maximizing the percentage of students meeting proficiency standards led to the category of "bubble kids," and a pattern of disproportionate attention to students whose improvement would most affect this metric (Booher-Jennings, 2005).

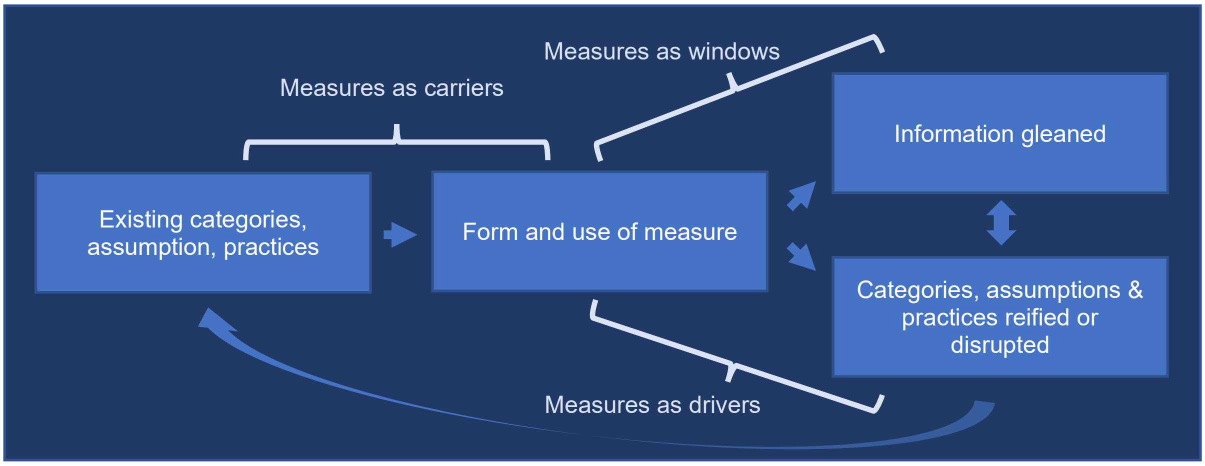

Figure 1. A developing conceptual framework for practical measurement as organizational structure.

In Figure 1, we illustrate how these different measurement metaphors reflect different aspects of the processes by which measures are created and used within their organizational contexts. Measures may *carry* assumptions and practices that shape their very form and how they are used; the form and use of measures in practice may in turn provide *windows* into desired information and may *drive* further reification or disruption of organizational perspectives and practices, which can then feed into further design and work with measures in an ongoing cycle. We argue that in order to understand and design for the use of practical measurement as part of a larger change process, educational leaders and researchers need not limit ourselves to treating—or conceiving of—measures solely as windows. Rather, we find it important to attend to the multiple ways that measures operate as elements of organizational structure. In our ongoing work, we are testing and refining this framework, partly in interaction with empirical examples of work with practical measures, described next.

Context and data

The current project is part of a design-based implementation research project (Penuel et al., 2011), in which university faculty and staff worked collaboratively with district STEM professional development (PD) leaders throughout the 2019-2020 school year to co-develop several practical measures of teacher learning.

Primary data sources for understanding how practical measures functioned as carriers, windows, and drivers in this context included the following: 1) initial interviews with four district PD leaders, focused on their own and their organization's goals for teacher learning and their experiences using varied sources of information to understand teacher learning, 2) recordings and artifacts from 27 co-design meetings involving iterative cycles of development and work with practical measures (in conjunction with PD sessions), and 3) iterations of the measures themselves. We treated interviews primarily as priming tools to understand the landscape and possible ideas and practices that might inform measure development and use. We then conducted content analyses triangulating across data sources related to two facets of the PD leaders' work: lenses on teacher learning (e.g., forms of instruction perceived to be easier or more challenging for teachers; valuing responsiveness to teachers' expressed needs), and approaches to measurement itself (e.g., quantitative vs. qualitative data; using questions consistently across PD series). We documented categories, assumptions, and practices related to both facets as expressed and enacted during co-design cycles. We also documented the sources of these ideas and practices as best we could and whether and how they were reified or disrupted as PD leaders used and refined measures.

Illustrative examples

While analysis of additional examples is ongoing, here we illustrate the conceptual framework in Figure 1 by comparing two distinct measures—one with origins in existing PD practice within the district, and one newly developed. Our brief vignettes are intended to highlight key parts of the framework, with particular emphasis on the less common metaphors of practical measures as *carriers* and *drivers* of organizational ideas and practices.

Measure 1: PD exit tickets

The first practical measure of teacher learning was an exit ticket, administered at the end of each PD session across series. It included several Likert-scale questions about teachers' perceptions of the quality of the session and how well it prepared them to understand and implement standards-aligned instruction, plus several open-ended questions asking what they found most valuable and areas of focus or improvement for the next PD.

The form of exit ticket reflected its function as a strong *carrier* of existing assumptions and practices, particularly around measurement. Indeed, the exit ticket's design pre-dated the project and carried existing questions and question types (specifically, the Likert-scale questions) intended to be kept consistent across departmental PDs. Multiple PD leaders expressed some challenges in gleaning useful information from the exit ticket as a *window*, describing how the questions elicited feedback from teachers' perspectives but were "not specific" (interview, 8/19/19) and did not often give "enough to know… how I need to shift my own instruction for teachers" in subsequent PDs (interview, 8/20/19). In a co-design meeting for a PD series focused on district curriculum (9/6/19), PD leaders noted that they would need to administer the exit ticket and briefly considered whether they wanted to add anything different to the measure, choosing not to do so prior to use. Nonetheless, in a debrief meeting following the PD, a PD leader quickly oriented to the exit ticket and specifically the Likert-scale items. They highlighted that the scores were largely positive ("higher than… last year" (9/30/19)) and used Excel to create averages across participants—a practice that had been used before with exit tickets, carried forward and further reified. In these ways, the form and use of the Likert scale exit ticket measures not only served as a *window* into teachers' perceptions of the PD, and *carrier* of prior measurement practices, but also a *driver*, reifying organizational valuing of teachers' perceptions of utility, practices of using average scores to interpret impact, and assumptions around comparability across PDs occurring in different years with different participants.

The exit ticket also seemed to function as an impactful *window* when PD leaders considered text-based responses to the question on areas of focus and improvement, which drove changes to leaders' thinking about teacher learning and corresponding changes to the sequencing of topics within the PD series. PD leaders interpreted this text by inductively generating two main categories of requests from teachers. Recognizing that one of those categories was not scheduled to be addressed until later in the year, leaders moved it up because of the "demand for it" (meeting, 9/30/19). Thus, the use of open-ended exit tickets as a *window* into teachers' priorities also facilitated their function as a *driver* of future PD design, including both the reproduction of existing session categories as well as the disruption of a prior assumption of how the sessions should flow to support teachers in learning to use the curriculum.

Measure 2: Problem of practice mapping

The second practical measure of teacher learning was a problem of practice mapping measure, which invited teachers in a professional learning community to articulate and explore a problem of practice they experienced in their classrooms. Given several topic areas to choose among (e.g., "discourse," "differentiation"), the measure included a series of open-ended questions—naming a specific problem within their selected topic area, what they currently saw in their classrooms, what they would like to see, why they thought the problem was occurring, and initial ideas of what they might try to address the problem.

In contrast to the exit ticket, the mapping measure was the subject of extensive co-design among partners. In developing the measure, PD leaders and partners built from a set of values shared amongst themselves and more broadly within the district—including working toward a shared vision of high-quality instruction (emphasized across interviews as a core district value), and naming and improving what's within your "locus of control" (co-design meeting, 9/18/19). They also worked to ensure that the measure was aligned with—or properly *carrying*—categories from district-level priorities. For instance, PD leaders grappled with whether common district foci should be named as the topic areas or be embedded across topic areas (ultimately choosing the latter, meeting, 9/9/19). They also brought in language from their own experiences with departmental strategic planning, framing what teachers would like to see as their "ideal state" (measure, 9/26/19).

In this example, the measure functioned as a *driver* for PD leaders' practice before it was even used with teachers. During a co-design meeting (9/18/19), leaders drew heavily on the measure's questions to plan for teachers' discussions during upcoming PD. Each question was allotted time for discussion, reifying the questions as key frames. Anticipating use also prompted negotiation of which questions teachers should come to consensus on; PD leaders decided that it would be important for teachers to agree on a desired ideal state, reproducing the value of working toward a shared vision in practice. This case illustrates how measures can *drive* the reification or disruption of existing assumptions and practices even without first being used in a traditional *window*-like manner.

Discussion

The posited conceptual framework brings two key lines of work into closer communication—work on practical measurement in improvement science, and work on measurement from an organizational theory perspective. Our examples illustrate clearly that measurement tools and practices do more than provide information, that is, they are not only *windows*. Rather, the very processes of designing and working with measures themselves can serve to reproduce and/or disrupt the categories, assumptions and practices operating in an organizational context. As such, the development of practical measures—intended to be interwoven with educational leaders' daily work—is also a process of developing organizational structures that *carry* and *drive* particular values and foci of attention and corresponding possibilities for organizational persistence and change. In some cases, these functions are interwoven with traditional *window*-like uses, while in other cases they operate somewhat independently. We hope that by attending more broadly to practical measures' multiple roles, we can likewise move forward with more holistic and effective approaches to educational improvement.

We would like to express our sincere appreciation to the district PD leaders in the study for their partnership and intentional design and use of practical measures.

Knowledge Creation Analytics for Jigsaw Instruction: Temporal Socio-Semantic Network Analysis

Ayano Ohsaki, Advanced Institute of Industrial Technology, ohsaki-ayano@aiit.ac.jp
Jun Oshima, RECLS Shizuoka Univ., joshima@inf.shizuoka.ac.jp

Abstract: This study aims to gain insight into how to design lesson plans with jigsaw instruction to promote knowledge creation. Collaborative learning has been discussed as a method for improving students' learning. However, little research on jigsaw instruction analyzed from the knowledge creation perspective has been conducted. Previous research has resulted in the development of the new temporal socio-semantic network analytics (SSNA) to emphasize the visualization of ideas changing during the knowledge creation process. Therefore, we conducted temporal analysis on students' learning of a more complex problem through jigsaw instruction than previous studies to examine the differences between high- and low-learning-outcome groups. The results of three investigations suggest that designing lessons such that they prompt students to engage in generative tasks can contribute to learning as knowledge creation.

Theoretical background and research purpose

In the learning sciences, collaborative learning has been discussed as a method for facilitating learners' deeper disciplinary knowledge. Among the many types of collaborative learning, jigsaw instruction is a method that has been examined in many studies (Miyake & Kirschner, 2014). Jigsaw instruction is comprised of two participatory structures of collaborative learning: expert group activity and jigsaw group activity. In expert group activities, learners in a group are given the same material to study collaboratively. Conversely, in jigsaw group activities, each learner provides others with new information and knowledge obtained during the expert group activity.

While most studies on jigsaw instruction have analyzed collaborative learning as knowledge integration in the belief mode (Bereiter & Scardamalia, 2003), few studies have examined how learners' attempts to improve their ideas as collaborative knowledge objects in the design mode from the knowledge creation perspective. In the knowledge creation metaphor of learning (Paavola & Hakkarainen, 2005), learners are assumed to practice knowledge creation by collaboratively constructing knowledge objects (Scardamalia & Bereiter, 2014). In previous research on the jigsaw instruction method from the aspect of knowledge creation, the results have suggested that students should engage in creating knowledge objects, and educators should design embodied learning in class through design-based research (Oshima et al., 2017). However, no studies have tried to discuss how to design elements of jigsaw instruction from the perspective of knowledge creation.

Evaluating learning as knowledge creation practice is challenging because it involves the collective nature of knowledge. The primary target in knowledge creation is the collective state of knowledge constructed by a community of learners, and to evaluate collective knowledge advancement in knowledge creation practices, it is necessary to develop analytics answering the following questions: (1) how is the collective nature of knowledge is represented, and (2) how is dynamic change represented over time (Scardamalia & Bereiter, 2014)? The socio-semantic network analysis (SSNA) of discourse has been discussed as a promising approach for answering these questions (Oshima et al., 2012). As an application of SSNA, KBDeX represents the collective nature of knowledge as clusters of words representing ideas used in discourse and visualizes how a word's network structure changes over time. KBDeX also calculates several metrics, such as degree centralities, for network structures. Previous studies (Oshima et al., 2017; 2018) have demonstrated how different high- and low-learning-outcome groups engage in their collaborative discourse in a jigsaw group activity to discuss future instructional interventions to support low-learning-outcome groups.

There have been critical developments in the SSNA algorithm since the first presentation of SSNA as a knowledge creation analytic for jigsaw instruction (Oshima et al., 2017). Recently, Ohsaki and Oshima (2021) developed a new algorithm by applying the lifetime connection between words in a network and the real-time scale in visualizing the trajectory of metrics over time based on studies in dialogism and network science. Their study revealed that temporal network analysis is more appropriate for finding critical points in the discourse for idea improvement than aggregative network analysis.

In this study, based on the developments in the SSNA algorithm in recent years, we examine how discourse in knowledge creation practice is related to learning outcomes to gain insights into how jigsaw instruction design can be improved with further instructional support. We approach the research purpose with the following research question: how does the engagement of students in the high-learning-outcome group in the discourse differ from that of students in the low-learning-outcome group?

Method

Data collection and study design

We used a dataset with undergraduate students' pre-tests, post-tests, and collaborative discourse in a jigsaw group activity collected during a lesson unit that was part of a course on science education. A group of primarily second-year students created presentations on an air conditioner's mechanism as a complex problem that integrated science, technology, and engineering knowledge. A total of 29 students from the biology and environment departments were divided into nine groups of three or four. The main challenge of the jigsaw activity was, "How does an air conditioner continue cooling a room?" In the expert group activity, each member studied the three different documents on (A) theory of heat, (B) phase change and thermal energy, and (C) pressure and temperature in a different group for about 20 min. Next, members from different groups created a new group for the jigsaw group activity. Then, groups took on the main challenge by creating a presentation over 24 min.

We designed this study based on previous research (Oshima et al., 2017). Before and after the lesson unit, a teacher conducted pre- and post-tests to evaluate individual learning outcomes by using a worksheet with the main challenge printed as a question. A total of 28 students completed both tests by writing or drawing their ideas. Moreover, students' conversations during expert and jigsaw group activities were video-recorded. We transcribed discourses in the jigsaw group activity to examine how students engaged in collaborative problem-solving techniques. There was an average of 260.22 (SD = 70.66) utterances.

Analysis

To examine the research question, we conducted three investigations based on Oshima et al. (2017; 2018). The first investigation defined the high-learning-outcome group as one in which all students integrated knowledge from learning resources. We analyzed students' writing and drawing on the pre- and post-tests by plotting their understanding of an air conditioner system based on the Structure-Behavior-Function (SBF) framework (Hmelo-Silver & Pfeffer, 2004). Students were divided into four categories from "no understanding" to "fully integrated understanding across three documents" using the same categories as Oshima et al. (2017). When students' explanations in pre- and post-tests considered the relationship among structures, behaviors, and functions described in learning resources, we concluded they successfully understood the document. The first author and a trained student belonging to the laboratory for learning sciences independently evaluated students' SBF frameworks based on their explanations in each pre- and post-test. In this evaluation, Cohen's Kappa coefficient for the agreement between the two raters was 0.97. Disagreements were resolved through discussion.

The second investigation analyzed students' collective knowledge advancement through discourse analysis using temporal SSNA (Ohsaki & Oshima, 2021) to visualize students' knowledge advancement transitions and define the pivotal points for in-depth dialogical analysis. We selected 28 terms to explain the main challenge by a teacher, keywords in the learning resources, and basic scientific terms. KBDeX calculated the transition in the total value of the degree centralities of terms as nodes in the network across discourse exchanges. Additionally, we divided the lesson into three phases to analyze this visualization in detail.

The third investigation was an in-depth dialogical analysis to assess how students acted with collaborative problem-solving mechanisms. We chose the results from the most active group from each category and analyzed their discourse data at the defined pivotal points in three phases of the lesson. This method was based on the hypothesis that a stage near the highest degree of centrality would display the characteristic activity.

Results

From the investigations, we confirmed that four groups had integrated SBF understanding. These four groups were the high-learning-outcome groups, and the other five groups were the low-learning-outcome groups. The individual analysis results showed that 10 students were fully integrated, 13 were partly integrated, five expressed a single understanding of the learning document, and none were in the no-understanding category. Chi-squared analysis of student frequencies across high- and low-outcome-groups (fully or partially integrated and the single document) showed significance ($\chi^2 = 31.36$, $df = 2$, $p < .01$).

In the second investigation, the transitions in the total values of the degree centralities in each group showed a striking difference between the high- and low-outcome groups regarding whether to maintain the word clusters' changes (Fig. 1). The images' vertical axes signify the degree centralities' absolute values, and the horizontal axes represent time. The lines for the high-outcome groups illustrate that students continually used keywords and tried to connect these keywords to various teams. This difference is especially evident in the late phase of the lesson. The low-5 group peaked at the end of the first phase and was slightly different from other low-outcome groups, but the change in the second phase is not shown in Fig. 1.

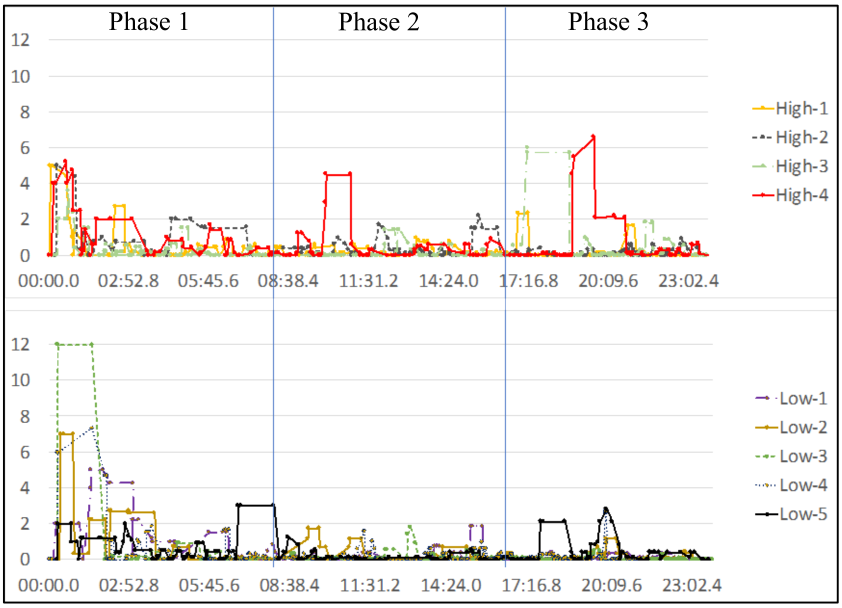

Figure 1. The transitions in the degree centralities of the high-learning-outcome groups (upper) and low-learning-outcome groups (bottom).

Dialogical analysis in the third investigation showed details in the differences between the high- and low-outcome groups. For this analysis, we chose groups high-4 and low-5. Next, we focused on pivotal points in each phase that were the highest for both groups because they show the group activities' characteristics. The first pivotal point for the high-outcome group confirmed that at 37 s, students shared knowledge from the documents. Then, they shared knowledge until the early timing (2 min 59 s) in phase 2, which is the second pivotal point. The pivotal point in phase 3 for the high-outcome group was at 19 min 38 s. By preparing the presentation, students checked their understanding. The original discourse data was in Japanese and was translated into English by the first author (keywords in SSNA are shown in italics). The discourse around the first pivotal point was as follows.

Student 4A (#5): In this document, *heat* moves from the high-temperature side to the low-temperature side, but it does not transfer from the low-temperature side to the high-temperature side. This is a physics explanation… *the second law of thermodynamics*. So, *thermal energy* moving with the material is called the *refrigerant*. It seems that a *refrigerant* carries *heat*.

Student 4C (#6): Hmm. *Refrigerant*….

Student 4A (#7): Right, so, yeah, at this… at this point, in the *condensation* and *evaporation* units, *thermal energy* moves between a *refrigerant* and the air.

Student 4C (#8): Hmm, hmm, hmm.

Student 4A (#9): This is the mechanism. Right. A *heat pump* mechanism transfers *thermal energy* from a cold space to a warmer one because of external *power*. It is similar to *an air conditioner*.

Even though, from Phase 1, the students in the low-outcome group started sharing the knowledge that they gained from the documents, the first highest point was marked when changing phases from 1 to 2 (around 6 min 52 s). At this point, they tried to learn the contents of document B because they had not engaged in sharing prior. Then, at the second pivotal point (8 min 34 s), dialogue data showed that students had tried to integrate knowledge collected from the documents. The low-outcome group's last pivotal point was shown at 19 min 58 s; it was close to the last high-outcome group's pivotal point. The students then discussed their understanding.

Discussion

This study's purpose is to improve the design of jigsaw instruction with further instructional support. Accordingly, this study raised the research question: how does the engagement of students in the high-learning-outcome group in the discourse differ from that of students in the low-learning-outcome group? The answer to this question can be discussed based on the shape of the graph in Fig. 1. The temporal SSNA delineated the high-outcome group's characteristic as a frequent shape consisting of a higher and lower score through all phases. Meanwhile, the transitions in the low-outcome groups' lines tended to both show the most dynamic changes at first and then relatively little change later. In addition, there were differences between the high- and low-outcome groups both in the value of the total degree centralities and the timing of change. Furthermore, it is suspected that the high-outcome group's members tried to create a common understanding based on other members' information from phase 1. This is because the line for high-4 in Fig. 1 delineates that they shared the documents' contents and mentioned many keywords during the first phase. The importance of creating a shared understanding has been discussed in previous studies (Oshima et al., 2017; Damşa et al., 2010). Additionally, moving to the stage of re-creating knowledge objects (namely, "generative collaborative actions") (Damşa et al., 2010) can also be attributed to the creation of shared objects from the early phase. Consequently, the present study suggests that epistemic goals and activity time are important in supporting low-outcome groups.

These findings suggest that when teachers support students to engage in a generative task, students may be more likely to engage in learning as knowledge creation. The low-outcome groups in the dataset could not engage in generative collaborative actions. Thus, redesigning the main challenge for smooth transitions to the generative task might prompt students to create a shared understanding and transition to generative collaborative actions. One possible main challenge may be to ask students "please explain why vending machines with heat pump systems are good for the earth." To solve this task, they need not only to integrate their knowledge but to generate their own idea based on knowledge from learning resources on an air conditioner as a heat pump system. This study contributed to the further development of jigsaw instruction as collaborative learning designs from the knowledge creation perspective, but it just analyzed a single case. In future studies, the hypothesis detected in this study should be examined by analyzing more data.

Abstract: The extant literature suggests that human-centered approaches to design such as Participatory Design (PD) lend to more reusable and relevant design outputs, but often assumes this progression as an inevitable outcome of PD work. To investigate the factors contributing to this assumption, we document a comparative case analysis of the design processes of three studies centered on learning in communal spaces. All three studies shared the overarching objective of designing signage to promote playful learning opportunities in grocery stores, providing a rare opportunity to analyze different approaches to PD work in a controlled design area. We compare how three components interact throughout each design process: 1) researchers' goals 2) researchers' pedagogical frameworks and 3) community roles. We propose that future researchers consider the interplay of these three components as points of deliberation to formulate innovative and intentional PD practices. We offer a set of guidelines incorporating these components that researchers can reference when structuring their PD process.

Introduction

Within the learning sciences, human-centered methods such as Participatory Design (PD) have received increased attention to create more culturally-relevant and reusable learning artifacts *for, with, and by* those who will use them (DiSalvo, Clement, & Pipek, 2012). PD opens up opportunities to integrate input from users to design outputs centered around users' values and contexts (Ahn, Campos, Hays, & Digiacomo, 2019). Nonetheless, to optimize this process, researchers must interrogate their goals, assumptions of how learning occurs and how that relates to the outputs they develop, and the way they incorporate community participation in tandem (Ahn & Clegg, 2018).

Researchers' goals largely stem from their assumptions about learning. The pedagogical frameworks that researchers bring to the design process influence their conceptualization of how learning happens during interaction with design outputs (Ahn & Clegg, 2018). For the purposes of this paper, we conceptualize the three following high-level pedagogical schools of thought. Cognition and learning can be conceptualized as occurring individually (cognitive), situated in interactions with others (social), or extrinsically being linked to interactions within a cultural-historical context (sociocultural) (Greeno, 2011; Nasir & Hand, 2006). These pedagogical frameworks undergird how researchers approach and structure PD; therefore it is important to name and reflect on how their pedagogical frameworks influence their facilitation.

Within PD, community members can shape the design outputs by taking on different roles —*users* of artifacts, *testers* who provide feedback, *informants* who contribute insight at multiple stages of the design process, and *design partners* who are equal stakeholders throughout the design process (Druin, 2002). As such, it is important to consider the types of contributions researchers seek from community members—and the corresponding relationships and capacities to best incorporate them. In this paper, we demonstrate how the structure of PD projects leads to different design pathways, and contribute a framework for researchers to characterize and structure PD in education. We provide a unique case study that examines the design processes of three community-based research projects that aim to design grocery signage that promote learning. These three studies are variations of a study conducted by Ridge et al. (2015) that found an increase in parent-child conversations when signage was installed in grocery stores. We posed the following research question: **How do researcher goals, researchers' pedagogical frameworks and community participant roles influence PD processes and outputs?** We propose a set of guidelines based on our findings to highlight elements researchers should consider when structuring future PD work.

Methods

To reveal the different trajectories research teams took to design signage that facilitates learning in grocery spaces, we analyzed the design process and outputs of three projects building on the work by Ridge et al. (2015). Projects 1 and 2 already completed initial stages of their research and Project 3 is an ongoing PD project conducted by our research team. We provide more contextual details of each study in our findings.

We conducted and transcribed interviews with five researchers from Projects 1 and 2 to learn about their goals, design process, and experiences working with community partners. We also transcribed Project 3's co-design sessions and collected researchers' written reflections following the sessions and subsequent signage development meetings. The final data corpus included 61 pages of interview transcripts, 56 pages of co-design session transcripts, and 17 pages of reflections/field notes of co-design sessions.

We used an emergent thematic analysis in two phases to understand the design process of the different projects. In an open-coding phase, the research team examined sample interviews and co-design sessions to develop an initial codebook. The research team met to discuss codes, refine code definitions, and combine and reorganize codes that had overlapping conceptual definitions. Then we assigned codes across our research team so that each one was double coded for intercoder reliability. The research team wrote analytic memos to capture the structural components of the design process that surfaced across the three projects (Weston et al., 2001).

Findings

In this section, we use vignettes to illustrate the varying interplay between the goals, pedagogical frameworks, and relationship configurations in each design narrative. We emboldened sections of each vignette to demonstrate how these components are apparent in the structures of each research project.

Project 1: Signs promoting math talk in supermarkets

Project 1 researchers designed signs based on predetermined theoretical content and food groups, and examined their effectiveness in promoting increased children's math talk in supermarkets (Hanner, Braham, Elliott, & Libertus, 2019). Grounding their design in cognitive and social learning frameworks, researchers used directive language tailored to different developmental levels in their signs. One researcher recalled, "*We decided to have **one question that was low level targeted at the younger kids** in our age range and then **one that would be slightly more advanced** that would require some arithmetic operation or more complex reasoning process **to engage the slightly older kids**."* For example, one sign asked, "How many eggs are in a carton?" to encourage younger children to count; another prompted slightly older children to subtract by asking, "If we each ate an egg, how many would be left?"

Project 1 researchers were firm on the content and purposes of their signs, and positioned their partners as *users* and *testers*. To gain permission for implementation, researchers discussed with the local grocery store managers to gain *tester* feedback on specific design elements that are allowed for the signs (e.g. dimensions, content), and *user* feedback on where to institute them. A researcher reflected "*[Some stores required] that **they would have to create the signs**. And that kind of ruins the whole point of the study. So we couldn't do it with them. [...] **I couldn't make [the signs] super wide because [the grocery store staff] wanted everyone to be able to walk down the aisle easily**...and they also didn't **want something that would promote a specific product**."*

Researchers were ultimately able to accomplish their goals, but initiating permission-based relationships with partners to use predetermined signs seemed to set constraints on initiating and facilitating more substantial engagement with community partners. One researcher recalled, "*It seemed like **we couldn't convince grocery stores that this would be a meaningful engagement with the community or** [...] **making a more meaningful shopping experience for the families**.*" The signs were highly usable in the space to study math talk. However, researchers' firm stances on design and the corresponding roles their partners took may have resulted in less alignment with community values.

Project 2: Signs promoting elaborative talk in a food pantry

Project 2 researchers relied on social and cognitive theories to develop signage to examine whether guided prompts elicited more elaborative dialogue between caregivers and children compared to signs with learning pronouncements (i.e. "learning can happen anywhere!"). Researchers collaborated with a food pantry in a low-SES neighborhood and talked to patrons and staff to inform their signage development and placement.

Researchers had defined the theoretical content of their signs but still looked to learn about how to best situate them in topics relevant to their context. A researcher described their considerations when drafting signage prompts: "[We wanted] *sort of **open-ended, what, why, the W questions... So it was very easy for the parents to elaborate on the guided play kind of questions** [in the signs].*" To create signs relevant to their context, researchers incorporated community partners (food pantry staff and patrons) as *users* and *informants* to learn about the culture, routines, and layout of the food pantry. A researcher reflected: *"We went in [the food pantry] once just to start to volunteer [...] So we spent a bit of time in there [...] **getting to know the culture of the place. We talked to the people in charge to see what items they typically got**, what sort of products always came in, no matter what...things like that. And **based on the layout of the food pantry was how we decided where we'd be putting the signs up**."*

Researchers used this information to situate their signs in relevant foods and context to food pantry patrons and study the signs' influence on elaborative talk. Nonetheless, a logistically-based relationship resulted in constraints on facilitating value-informed participation with community partners. A researcher reflected, *"[Our partner organization]* ***really wanted an evaluator, not a scientist or researcher****, so* ***it was sort of one of those fundamental bad fit situations****."* Incorporating community partners' insight helped researchers optimize the signs' relevance and usability in the space, but ultimately did not abate several misalignments between researcher and community partner goals in the PD process.

Project 3: Signs promoting culturally situated STEM learning

In Project 3, we used cognitive, social, and cultural pedagogical frameworks to produce grocery store signage prompting conversations around STEM learning situated in local values and supermarket experiences. We conducted two co-design sessions with 20 participants—researchers, partners from a local health organization, and caregivers from a low-income predominantly Latinx community. In each session, participants recounted their grocery store experiences.

A researcher reflected on the goals of the project: "*This project looks for any underlying factors [...] within the family or in these participants' communities. It is important for us to find these factors so that we can* ***create posters relevant to this community's needs***." As such, we situated community partners as cultural *informants* with expertise in local cultural and lived experiences. Some of the values we heard were: familial connection, emotion, routines, and cross-cultural comparisons. For example, some parents (as immigrants to the United States) expressed frustration around changing from metric to imperial measurement systems: "***The children*** *[...]* ***they already know about pounds. But us as adults, in the butcher shop, [deciding between] a kilo and a pound*** *[...]* ***we're thinking it's a kilo, we get a pound****."* We drew upon cognitive skills involved in STEM learning that we heard in community members' stories—such as measurement unit conversion—to develop signs promoting interactions situated in local experiences, needs, and culture.

We defined content for our signs by conducting a thematic analysis on the data from our sessions. To translate the themes into signage ideas, we posed questions with the stem "How might we" coupled with the themes we saw arise in the data to try and prompt STEM learning interactions. One example question we posed was, *"How might we promote activities to convert different quantities, measurement systems or cultural ways that we measure?"* From this question, we developed a conversion table that families could use to convert between metric and imperial systems at the deli. However, at the current stage of our project we have not yet included community partners as *users* and *testers*, so we do not know whether families would engage with design output as desired.

Conclusion, limitations, and implications

This case study presents a unique opportunity to look across similar projects and examine how researchers' choices in each stage of the design process lead to different design directions. Our analyses shed light on the interplay of three critical components—researcher goals, pedagogical frameworks, and community roles—in PD processes. We found that researchers' pedagogical frameworks and goals across each project influenced how they structured the design process and conceptualized community roles.

Based on how community members are situated in partnerships, the constant incorporation and negotiation of researcher and participant input into design can result in a process of mutual learning (Yip et al., 2016). However, we acknowledge as a core limitation that none of the teams referenced in this paper has yet developed mutual learning opportunities in their PD. Work involving communities is inherently more complex due to the increased number of constituents; executing PD to its full potential therefore demands heightened intentionality and reflection in how to best incorporate these constituents. To support this process, we propose a set of **G**oals, **P**edagogical frameworks, **P**artner relationships (GPP) Guidelines (Figure 1) future researchers can use to highlight considerations around three key components when structuring their PD. By reflecting on these guidelines in the planning phase, researchers can harness PD approaches more effectively in complex community-based work and abate any foreseeable misalignments. Future researchers who aspire to maximize PD can use these guidelines to yield more usable design artifacts and sustainable interventions that incorporate community voices and promote mutual learning.

Identifying Research-Practice Tensions and Belief Shifts through Co-Design Processes

Masaood Ganaiem, Al-Rowad for Science and Technology, Masaood.ganaiem@alrowad.org

Abstract: In this paper, we examine an experience of using co-design methods with Palestinian Arab educators and Learning Sciences researchers. In this research-practice partnership, we used a participatory methodology to generate new ideas for transdisciplinary STEM activities. This approach allowed researchers and educators to build trust, facilitated a better understanding of the local context, and enabled new educational possibilities to emerge through speculative design. We describe the collaborative process to create STEM learning environments for non-dominant learners in a settler-colonial context and highlight tensions we observed between research aspirations and practical constraints.

Introduction

This paper is part of a larger project that aims to study the engagement and participation of a non-dominant population of Palestinian Arab learners in transdisciplinary science activities. This is a collaboration between learning science researchers at Arizona State University and educators at Al-Rowad for Science and Technology, a community-based organization led by Palestinian Arab educators in the Haifa District in Israel. The organization is engaged in STEM education through science hands-on activities, after-school programs, and public science outreach events with Palestinian Arab youth and children in Israel. Through this collaboration, we drew on multiple design methods to strengthen the partnership and speculate about possibilities for designing equity-oriented STEM education environments in their context (Bang & Vossoughi, 2016; Dunne & Raby, 2013; Freire, 1973; Vossoughi & Gutiérrez, 2016). Through this work, we hope to expand on how participatory research with local communities can "disrupt historically shaped inequities and cultivate transformative agency from within communities" (Bang et al., 2016, p.29), position community members as experts, and strengthen research-practice partnership through critical pedagogy and dialogue. These efforts have the potential to shift power and authority away from researchers and toward collaborating with members of the local community, who have a deep understanding of the social and historical complexities at play, and the challenges and constraints underlying pedagogical decisions. As such, this work has implications for researchers who conduct research with non-dominant and historically oppressed populations.

In this paper, we describe the methodological choices we had when conducting co-design workshops to create educational experiences that consider equity, collaborative and interactive engagement, and learning with technology. In this work, we build upon participatory methods to involve participants in thinking about educational possibilities for their work (Bang & Vossoughi, 2016; Frerie, 1973). In this process, we used design fiction prompts to speculate such possibilities and engage practitioners to think about expansive possible futures of their work (Dunne & Raby, 2013). We frame this work as co-design to emphasize the role practitioners can play in research-practice partnerships. We use data from notes and transcripts from three sessions (6 hours total) to examine how co-design can be used as a methodological tool that positions collaborators as experts and enable productive dialogue within research-practice partnership. In addition, we examine if and how participants, including the researchers, experience shifts in thinking about learning, equity, and pedagogy through this process.

Positionality

As our identities as researchers and practitioners are a critical component of this research, we begin with a description of our positionalities.

Areej Mawasi, Researcher: I am an insider researcher in the broader context of the fieldwork. Both my undergraduate education in Israel and graduate studies in the United States were Western and Eurocentric. My fluid learning trajectories across contexts, geographies, languages, cultures, and methods enabled me to engage in scholarship across disciplines, paradigms, and geographies (Said, 2000). Within this partnership with the organization, my role was dynamic, initially I was an outsider and viewed as a researcher who was there to observe and make recommendations. Gradually, as our communication and trust increased, my role shifted and our collaboration grew stronger. In this project, I co-designed and facilitated the workshops, conducted and shared observations, analyzed and interpreted the data, and I was the lead author on this paper.

Ruth Wylie, Researcher: I am a white woman who was born and raised in the southwest United States. I have attended public and private universities in the United States and have training in Cognitive Science, Computer Science, and the Learning Sciences. My research focuses on supporting interdisciplinary and diverse teams to tackle global issues. For this project, I advised Areej on the design and execution of the workshops, participated in interpreting the data, and drafting the manuscript.

Wisal Ganaiem: I am the pedagogy and education counselor at Al-Rowad. I have a Master's in Educational Counseling. For this study, I shared with Areej insights on areas of interest of Al-Rowad in social change and science education, overview of practices we do with instructors (e.g., professional development, STEM pedagogy), and populations we work with. I also shared feedback on the structure and topics of the co-design sessions in alignment with instructors needs, and I fully participated in the co-design sessions.

Masaood Ganaiem: I am a scientist and team leader in research and development innovation. I grew up in Baqa Al-Gharbia and studied at a private school in Haifa. I hold a Ph.D. in immunology from Ben Gurion University in Israel. During my research career, I noticed a low number of Arab scientists in Israel. In 2013, with my wife Wisal and Arab academic fellows, I co-founded a non-profit organization called Al-Rowad for Science and Technology, with a vision to overcome the socioeconomic and geographic challenges and disadvantages in science education facing the Arab community in Israel. When we met Areej, we noticed commonalities in education perspectives and pedagogical practices; this encouraged us to collaborate on this project. Our collaboration helped us understand the potential impact of Al-Rowad's framework beyond our local community.

Participatory co-design research

For this study, we drew upon participatory approaches. Our goals were to create partnerships in which we co-construct knowledge with educators through co-design activities, challenge deficit-focused views of local communities' efforts in changing their realities and understand pedagogical practices in the learning environment from the educators' perspectives, not only through the researchers' lens. The organization volunteered to collaborate on this project because they were interested in expanding their impact through academic research beyond the local community. This work is conducted within a community-based organization, with Palestinian Arab educators. To better understand the existing practices and learning within this context, we conducted three co-design sessions over two days (6 hours total) with educators from the organization, to learn with them about the pedagogy and design of equity-oriented STEM environments for non-dominant Palestinian learners. Data for this paper includes video transcription of the sessions, design artifacts created during the sessions, and field notes.

Our partnership follows the characteristics of traditional co-design work. For example, (1) the work follows a non-linear process to implement innovations in real-world learning environments (e.g., Barab, 2014); (2) the work values interdisciplinary partnerships between researchers and stakeholders such as teachers, learners, parents, and administrators (Penuel & Spillane, 2014; Zuiker et al., 2017); (3) the work views learners and teachers as co-designers through participatory design processes that aim at thinking about educational possibilities (Bang & Vossoughi, 2016; Freire, 1973); (4) the work attends explicitly to the social, cultural, and political context in which these design activities take place (Bang et al., 2016; Bang & Vossoughi, 2016); and (5) the work uses design approaches to engage educators with thinking about possible futures within their pedagogy and learning environments design (Bang & Vossoughi, 2016; Dunne & Raby, 2013; Freire, 1973).

The co-design participants were 6 educators from the organization (2 lead instructors, 2 assistant instructors, Wisal (Third Author) as the pedagogy and education counselor, and the STEM pedagogy director and co-founder) and the first author. The sessions focused on the following themes: equity in STEM; collaborative learning; and learning with technology. During the sessions, participants engaged in discussion and presented their ideas. The sessions were followed by three design challenges to identify educational possibilities.

Preliminary findings

The findings suggest that co-design fiction can serve as a method to envision possible educational designs within an existing context. These findings highlight (1) tensions between research and practice, (2) shifts in the perceived role of researchers within the environment, and (3) shifts in what counts as learning.

Tensions-between research and practice

Educators made generative design suggestions such as integrating collaborative activities, proposing ways to add digital media tools, and suggesting modified activity flows to incorporate these activities within their existing practices. While these ideas aligned with the goals of each co-design session, we see this as an initial step. We had hoped our conversations about social and political issues within this context (e.g., diverse ways of knowing, marginalization, corruption, violence, hegemony in science) would lead to participants generating more transformative educational ideas. One possible explanation is that the educators were designing educational possibilities constrained by the existing status quo of the context of their work and mediated by the prompts that the researchers designed (e.g., the ICAP framework (Chi & Wylie, 2014)—Interactive, Constructive, Active, Passive—for use in the design of collaborative activities). It is clear that the organization is committed to social change through their education work, but they must navigate their existing social, cultural, and political contexts in a pragmatic way to provide an entry point to science education for a large number of Arab students across many towns and cities, including unrecognized Bedouin villages.

Perceived role of researchers within the environment

As mentioned above, Areej is from the local community where the organization functions. Areej had not previously been involved in work with the organization. Because of her status as a researcher and her training in the United States, the educators originally viewed her role as an expert, consultant, or evaluator. When asked their expectations for the co-design sessions, educators initially expressed that "they want[ed] to learn from [her] so they can improve," but also, "they know that [she is] here to do research." This shifted when Areej emphasized that she was there to learn *from* them and *with* them through a co-design process that aims to co-construct knowledge. For example, when Areej shared a slide with observations and emerging themes from previously observed practices, participants were surprised and questioned if Areej had been analyzing them as they completed the workshop activities. While the conversation was humorous in tone, it suggests that participants perceived the research process as something that is done "on people" rather than "with people." Throughout the co-design process, it became clear that the researcher was interested in working with the educators and to co-construct knowledge and expectations. Areej frequently sought feedback on her interpretations and perceptions. Through this process, trust was built and conversations became more open to constructive critique. One participant reflected, "the source of critique and how it is done makes a difference… if Areej shares suggestions, it is clear to me from the talk that it is for improvement." Session transcriptions suggest that the educators were able to shift their perceptions of the Areej's role and began to view the co-design sessions as a collaborative experience, while also increasing their level of trust. At the end of one session, Areej shared her preliminary observations and encouraged the members of the organization to continue exploring these themes in order to share principles with other organization or in other learning environments. In response, two participants said, "around the world," referring to conversations about using their expertise working with non-dominant learners to benefit other contexts. This shift in discourse changes the view from that of a researcher studying the educators to that of the researcher collaborating with and learning from them. Despite the initial power dynamics between researchers and practitioners in the context, the co-design process built trust and helped educators from the organization position themselves as active collaborators rather than simply passive participants.

What counts as learning

The educators' sense of what counts as learning also shifted throughout the co-design process. In our discussions, we talked about learning-by-doing in an out-of-school context (e.g., knowledge of a peasant farming their land, a woman organizing her spices in patterns). One participant disagreed about whether or not these examples constituted learning. The participant argued that these examples were people "robotically" doing things without thinking, while another described how his Palestinian illiterate grandmother, who is from an ethnically cleansed village of Al-Damun (see Zochrot - Al-Damon, 2014), creates mathematical geometry and patterns through sewing and embroidery that "a Doctor in Math cannot do." This example demonstrates that the educator's grandmother was not simply engaged in passive apprenticeship; she was creatively making and constructing new ideas and art using mathematical knowledge that she was able to transfer to others to maintain her village's history, culture, and knowledge. This example provided a possibility for the first participant to think about diverse ways of knowing, and this change in perspective was reflected in his descriptions later in the sessions, where he noted that he sees such examples as creating new things beyond what was taught. We believe such an exchange was possible because of the examples Areej shared with the practitioners in an attempt to engage them in decolonial discourses about science education in this context.

Conclusions and implications

The design research process is often described as iterative, interventionist, and involving retrospective analyses (Barab, 2014; Bannan-Ritland, 2003; diSessa and Cobb, 2004; Collins et al., 2004). While researchers have different views about the appropriate level of participant involvement in decision-making, these perspectives are informed by researchers' epistemologies, observations, participant feedback, and data collected across design cycles. We view iterative, interventionist, and researcher-centric approaches as problematic for work with non-dominant populations and community-based educators. Using a top-down colonial approach, centering researchers' voices or the priorities of funding institutions, and focusing on "research and scientific outcomes" minimizes participants' contributions and reproduces research and design that does not cultivate the knowledge and wisdom that local communities and educators already have. As we continue to engage in design research in the Learning Sciences, we argue for the following practices: (1) researchers' priorities should be shifted towards collaborative learning with educators. For instance, involving instructors in the co-design process, as a way to learn about their pedagogical practices, share with them about the theoretical and implications of such approaches, and co-design educational possibilities collaboratively (e.g., Bang & Vossoughi, 2016); (2) building trust by involving the leaders and members of organizations in decisions related to research activities (e.g., discussing with instructors, logistical decisions, involving parents in the study); (3) understanding the existing practices of the educators and community; and (4) engaging in designing learning environments where we dialogically exchange expertise with educators and community members.

Design research amplifies collaboration between multiple stakeholders (e.g., researchers, educators, instructional designers, policymakers, parents, students) (Zuiker et al., 2017). Such collaboration enables the design of tools and the implementation of studies that meet multiple goals (Bannan-Ritland, 2003). Education systems and learning are complex; therefore, designing and developing interventions to improve learning requires diverse research methods that involves perspectives of nondominant local communities and participants. Such perspectives are not always considered in the design process, particularly in contexts where education systems are oppressive, racist, and engaged in discrimination against non-dominant populations. Through our work, we attempted to create a research-practice partnership where we brought together learning scientists and practitioners. These diverse perspectives enable a deeper understanding of the local context and its social, cultural, and political aspects that shape the local community practices.

Conceptualizing Critical Game Design as a Method to Engage Youth with Critical STEM

Areej Mawasi, Arizona State University, amwassi@asu.edu
Elisabeth Gee, Arizona State University, Elisabeth.gee@asu.edu

Abstract: This conceptual paper examines the educational affordances of critical design as a pedagogical tool for youth engagement in critical STEM learning. We conceptualize a critical design approach for using game design as a medium for critical STEM learning. First, we define critical design for the purpose of the paper; second, we discuss why critical design is important for STEM learning, and third we address ways in which critical design approaches might be applied through critical game design. We propose that using critical game design to engage youth creates educational possibilities for thinking and communicating about the social, political, ethical, and historical dimensions of STEM.

Introduction

In this conceptual paper, we draw upon work in critical design, critical STEM learning, and game design to examine the educational affordances of critical game design to engage youth with fundamental STEM issues (e.g., ethics, ideologies, history, biases within STEM). Through these three lenses, we expand thinking about the potential of games as media to support design thinking and STEM literacies (e.g., Parekh et al., 2019) while attending explicitly to the social, cultural, ethical, and political dimensions of design. We view this approach as an opportunity to support transdisciplinary STEM learning (e.g., Sengupta-Irving & Vossoughi, 2019; Takeuchi et al., 2020), engage learners in communicating STEM issues through critical game design in a participatory manner (e.g., Literat et al , 2020), and position learners with greater agency through their design process.

We view design as a non-linear, dynamic, and complex process that involves decision making, thinking, and doing shaped by ideologies and values of designers, practitioners (e.g., teachers, stakeholders), researchers, and participants in the design process (Mawasi et al., 2020). Attending explicitly to social, cultural, ethical, and political ideologies embedded in design processes and outcomes (including artifacts, systems, and knowledge) is crucial for more equitable, inclusive, and transformative STEM learning experiences and practices (Barab et al., 2007; Bang & Vossoughi, 2016; Medin & Bang, 2014). This attention challenges the presumed social and political neutrality of design thinking models and prompts learners to explore the values, interests, and standpoints instantiated in and reinforced by designed objects and the larger practices or systems in which they are used (Barab et al., 2007; Mawasi et al., 2020). Such examination can engage learners in critical design efforts that question existing designs, enhance learners' experience of agency in design (e.g. Aguilera et al., 2020), and expand their critical interpretive and meaning-making capacities (The New London Group, 1996). Recently scholars have challenged the cultural, racial, and economic agenda of dominant forms of STEM education (Vossoughi & Vakil, 2018) and called for STEM education in which "liberatory politics and deep disciplinary learning co-exist and co-develop" (Vakil & Ayers, 2019, p. 455). In this paper, we join this conversation by providing speculative reconfigurings of how critical game design as a learning activity might engage learners in critical STEM.

Game design has multiple affordances for engaging learners in critical reflection on dominant design goals, processes, values, and assumptions (Flanagan & Nissenbaum, 2014). Among these affordances are the interactive and systemic nature of games; games engage players through goals and actions that comprise "figured worlds" reflecting culturally and socially contexts of meaning (Holland et al., 2001). Prompting learners to think about values reinforced by their own and others' design artifacts can help them identify and evaluate the ideologies these designs reflect (Thumlert et al., 2018). While Flanagan and Nissenbaum (2014) and other design educators offer strategies to prompt designers' reflection on values in games, such critical approaches have rarely been applied specifically to game design in STEM. Additionally, educational games that expose learners to societal and ethical issues within STEM fields typically are not designed by learners, rather, they are used as an educational tool to teach STEM related concepts and practices (e.g., Barab et al., 2010).

Building on such work, we first define "critical design," drawing on concepts and strategies from several different fields. Then we discuss critical game design as an opportunity to engage youth in STEM learning that enables them to actively engage with and challenge restrictive and inequitable ideologies and practices.

Critical design across disciplines

Various disciplines offer somewhat different conceptions of critical design that inform our approach to critical game design in STEM education. Here we briefly identify key ideas from industrial design, human-computer interaction, game design, and the learning sciences.

Critical design in industrial design

Within industrial design (also known as product design), critical design arose as a means to "challenge how people think about everyday life" (Dunne & Raby, 2013, p. 45), particularly about the nature and role of designed objects, and to encourage people to imagine different possibilities (Dunne & Raby, 2013). Malpass (2017) describes critical design practice within the industrial design field as an approach that aims to use design as a medium of inquiry for facilitating "ways of knowing, exploring, projecting, and understanding the relationship between users, objects, and the systems that they exist in" (p.43). The goal of critical design is not a new or more desirable product, but rather to prompt questions about the values a product reflects, the assumptions it operates within, and the ideologies embedded and enacted within design methods, tactics, and strategies (Dunne & Raby, 2013; Malpass, 2017). For instance, Malpass (2017) describes how critical designers employ satiric devices such as humor and irony to provoke trenchant critiques of hegemonic values associated with production and consumption. However, as Dunne and Raby state, critical design is not intended to be entertainment, nor a form of art, but a means of "making abstract issues tangible" particularly as these issues are instantiated in everyday objects.

Critical design in human computer interaction

Scholars such as Bardzell and Bardzell (2014) have extended the concept of critical design to the field of Human-Computer Interaction (HCI). Building on Dunne and Raby's view of critical design as means of changing perspectives and prompting new insights, Bardzell and Barzell define critical design as "a research through design methodology that foregrounds the ethics of design practice, reveals potentially hidden agendas and values, and explores alternative design values." (p. 3297). The authors provide a more detailed and multifaceted conception of criticality, drawing on ideas from critical theory as well as metacriticism. They also argue for a broader conceptualization of what "counts" as critical design, including some forms of art as well as designs that may not be intentionally subversive but ultimately raise awareness of underlying ideologies and biases in design processes and goals. Lastly, they critique Dunne and Ray's distinction between affirmative and critical design, noting that any given design can both affirm and critique various aspects of the status quo.

Critical design in games design

In his classic essay on toys, Roland Barthes (2012/1957) describes how children's toys, as representations of the adult world, reflect broader social and political ideologies and structures that communicate appropriate and desirable ways of being and knowing. Even the use of cheap plastic for many toys reinforces a disconnection between human designs and the natural world. Barthes' view is illustrative of the work of scholars who study the broader social and political dimensions of play. Scholars in the field of game studies have addressed the implications of play across different levels of modalities (systems, procedures, visuals, symbols etc.) through analysis of games, game mechanics, and game design (e.g., Bogost, 2010; Salen & Zimmerman, 2004). Games as a medium in this sense can take different forms, digital or analog. A particular emphasis has been on how game rules and processes - the "procedural rhetoric" of games (Aguilera et al., 2020; Bogost, 2010; Salen & Zimmerman, 2004) - reflect beliefs about how the world works.

Critical game design includes approaches that prompt game designers to reflect on and challenge the values and assumptions that may influence their own design processes (Flanagan & Nissenbaum, 2014) as well as the creation of games with the deliberate intent of provoking critical thinking among players about the values, perspectives, and ideologies a game reflects (e.g., Cassar, 2013). In this sense, game design becomes not the creation of entertainment but a form of activist critique and advocacy for a social issue (e.g., Games for Change Student Challenge). Critical game design can also engage players in critically examining game mechanics, narratives, and representations. This perspective illustrates how play and procedurality within games mediate meaning making that can reproduce or challenge ideological systems and values.

Critical participatory design in learning sciences

The growing attention in the learning sciences to social, political, and ethical dimensions of learning has contributed to interest in participatory design approaches (Bang & Vossoughi, 2016). This includes the use of participatory research methods that shift power dynamics between researchers and participants and leverage diverse ways of knowing (Mawasi et al., 2020; Vakil et al., 2016). These methods might be considered critical in the broad sense of challenging dominant assumptions about whose voice and knowledge "counts" in the research process. However, some researchers have adopted more overtly activist strategies that involve participants in identifying questions, designing research approaches and identifying their desired futures or educational possibilities (e.g., Bang & Vossoughi, 2016; Tzou, et al., 2019). For example, in their participatory design research approach Bang & Vossoughi (2016) account for critical historicity, power, and relational dynamics within design methods themselves, creating opportunities to transform existing practices towards transformative educational change, rather than reproducing inequities as an outcome of design processes. The authors invite us to consider what they call axiological innovation, that is, thinking about meaning-making mediated by aesthetics, theories, practices, values, and ethics in design processes (Bang & Vossoughi, 2016). Another example is critical design ethnography described by Barab et al. (2007) as an approach that explicitly addresses power issues and agendas within the design process and its outcomes.

Critical game design: An approach to engage learners with critical STEM

A commonality across previous work on critical design is explicit attention to how dominant design processes, artifacts, and consequences reflect and reinforce social, political, cultural, and historical agendas. Design is re-imagined as a means of calling into question these agendas. Engaging learners with such critical design approaches in STEM may contribute to broader efforts to recruit marginalized populations to STEM, develop more inclusive and ethical design practices, and challenge dominant ideological dimensions of STEM education.

STEM education continues to be dominated by Western ideologies of scientific knowledge, practices, and excellence (Medin & Bang, 2014). Critical STEM education has been proposed as a way to help students think critically about their own engagement with STEM in school and in daily life, understand the historical, political and ethical dimensions of STEM, and see the potential of STEM to contribute to a more just and equitable society (e.g., Sengupta-Irving & Vossoughi, 2019; Takeuchi et al., 2020). Building on Freirian notions of critical pedagogy, scholars propose that critical STEM education should explore how normative discourses in STEM shape the construction of STEM knowledge and strategies, and position learners to challenge biases and inequities by cultivating their ability to create and use new tools and methods for knowledge creation and representation (Vakil, 2014; Vossoughi & Gutiérrez, 2016). We propose that design approaches such as critical game design can play a central role in critical STEM education as a means of engaging learners not only in critique but in creating artifacts and experiences that offer new forms of engaging with STEM.

Our own interest in critical game design grew out of our previous experience with using game design to engage young people in design thinking. In this earlier work, we hoped to engage participants in designing games that addressed social issues of relevance to their communities and that were personally meaningful. We adopted a popular model of design thinking as a framework. In analyzing the participants' design process and game artifacts, we discovered instances of "spontaneous" critical reflection. For example, in creating a game about water pollution, participants argued over whether the game should be competitive or collaborative, and questioned assumptions that individual actions alone might be effective in addressing this problem. In another game focused on the problem of agricultural pollution, the youth designers rewarded certain game actions with food from Taco Bell, an ironic means of illustrating our often unconscious participation in the very systems that we critique. Such examples inspired us to seek ways to more deliberately support youth engagement in critical game design.

Our conception of critical game design is still evolving, but we offer some conjectures about this approach to critical STEM education. Critical game design as a pedagogical approach may and should encompass a variety of experiences, topics, and goals. In contrast to models of design thinking that offer simplified steps and toolkits, the process of critical game design can't be reduced to a recipe. Indeed, we anticipate that a critical approach will prompt participants to question some common design techniques. They might question popular strategies for "empathizing" with potential users, or observe how power relationships are implicitly reinforced in relationships between game designers and players. Critical game design does not have to consist of designing entire games; learners can be introduced to ideological aspects of games through playing and critiquing existing games with a STEM focus. Emphasis might be placed not only on how STEM is represented through narrative or visuals, but also how game play itself reinforces values such as competition or collaboration. Learners can redesign existing games as a means of challenging or re-imagining existing STEM practices, goals, and ideologies. They can design games intended to provoke critical reflection on STEM-related issues. There are a small but growing number of games created for social critique that may serve as inspiration. Even a game design challenge without an overtly "critical" purpose can be a starting point for critical reflection. At the same time, designing games should be integrated with other forms of STEM education to cultivate learners' understanding of fundamental STEM concepts and tools. Ideally we view this as a reciprocal process; as learners grapple with representing STEM issues through games, they may come to a deeper understanding of, for example, current theories about environmental systems, or the nature of scientific models. Game design offers considerable potential as a context for learning; we hope to provoke greater attention to its *critical* potential as well.

Community of Practice in a Physics Department: Double-Majored Students' Perspective

Hien Khong, Shams El-Adawy, Eleanor C Sayre
hienkhong@ksu.edu, shamseladawy@ksu.edu, esayre@ksu.edu
Department of Physics, Kansas State University

Abstract: This paper explores undergraduate students' experiences in a physics department compared to the departments of their second majors (education and mathematics) in the light of the community of practice framework. We interviewed double-majored students at an urban US masters-granting institution to examine their sense of community in each department. We found that while the community of practice is strongly established within the physics department, students feel a weaker sense of community in their secondary departments, despite taking a similar quantity of classes in the other departments. The physics department has a strong community in part because of the activities of physics faculty: group work in classes, accessible research, and participation in scientific events. In this paper, we present narrated experiences of two case studies where we examine the nuances of their sense of community and the factors that strengthen the perceived physics community.

Introduction

The connection between students and related communities can have a long-term effect on professional development and persistence in a discipline (Hunter et al., 2007; Irving & Sayre, 2014). Understanding how students perceive the community that they belong to is an essential part of curriculum development aiming to increase students' sense of belonging and participation in the community. As a part of such projects carried out in an urban institution, this work attempts to understand how students perceive their communities through their learning and working experiences.

We investigate students' sense of community using communities of practice (CoP). A CoP is formed by a group of people who share similar interests and foster those interests through shared activities (Wenger, 1998). An authentic community where learners share goals, skills, values, and other knowledge can increase achievements through interaction between members (Davidson & Kroll, 1991). Physics education literature has used the CoP framework in both formal and informal learning contexts to analyze the process by which learning assistants develop their physics identity (Close et al., 2016), examine identity development of upper-division physics students (Irving & Sayre, 2014), or study physics identity development outside of academic setting through informal physics programs (Fracchiolla et al., 2020).

Through two case studies of students with two majors at one institution, we claim that they perceive their primary department (physics) as a stronger community than their secondary departments (mathematics and education). The main factor that makes physics a strong departmental CoP is the faculty's pedagogical choices. They intentionally design courses which focus on collaborative group work, and encourage students to be a part of the community through interactive events and activities, especially through research. We support our claim with narrated analysis in the light of the CoP framework. Implications of this study include identifications and better understandings of factors that support students' sense of belonging to the community, which can lead to better future design for curriculum development.

Theoretical framework

Wenger defines CoP as groups of people who share the same interest in a topic through which they will learn and do things together to make their interest grow. According to Lave and Wenger (Lave & Wenger, 1991), the three main characteristics of CoP are: joint enterprise, mutual engagement, and shared repertoire. (i) Joint enterprise is a set of shared interests, goals, and passions that members of the community collectively engage in and hold each other accountable to. The topics of interests can be renegotiated by members as long as the commitment to sharing them remains. (ii) Mutual engagement refers to the set of interactions that members do together such as discussions, resource sharing, and relationships building which enable them to learn from each other. (iii) Shared repertoire refers to routines, tools, ways of doing things, etc. developed through mutual engagement. A group must have these three core characteristics to be considered a CoP. While all CoP have the same characteristics, they can hold a variety of forms: some are large and broad such as the community of physicists in the United States, while some are small and local such as a research group at a university. An individual can participate in several CoP concurrently. For example, a female physics student can be an active member of a cosmology research group and an active member of a women in physics group. Active participants in different CoP have opportunities to learn and develop their interests within each community. A CoP may involve many participants who can be either peripheral (newcomers) or central (old-timers). Through mutual engagement, over time peripheral participants may build up their own trajectory towards being central members through knowledge and skill development. Different communities might take different amounts of time in the trajectory to become central members (Irving & Sayre, 2014).

This paper focuses on examining a sense of community in the physics, education, and mathematics departments within one institution. For this purpose, we center the mutual engagement component of the CoP framework without deeply considering joint enterprise and shared repertoire. All students coming to each department share the goals of acquiring disciplinary knowledge and skills, and mapping their long-term career trajectories. In addition, in each community, there is a set of common norms within the community to communicate and construct knowledge. For example, students and faculty in the physics department share a similar interest in enhancing our understanding of how the universe works (joint enterprise). The physics community communicates through mathematics and computer programs to construct their knowledge (shared repertoire). With that joint enterprise and shared repertoire assumed across departments, the goal of this study is not to determine what set of activities constructs a CoP in all three characteristics of the framework. Instead, we highlight the mutual engagement component, and examine to what extent mutual engagement affects students' sense of belonging in their community. We present narrated analysis through the lens of CoP, mostly focusing on mutual engagement to show how students feel more connected to their primary department compared to their secondary departments.

Context and methodology

Participants in this study were recent alumni and current students from the same master-granting urban institution in the US. It provides a wide variety of programs with more than 130 undergraduate and 175 graduate programs. The physics, mathematics, and education departments each offer major, minor, and combined degree programs for undergraduate students. Beside courses, physics and mathematics faculty also actively engage in research in various subfields, and structure their research so that undergraduates can participate.

Our research conducted 20 interviews focusing on students' career planning, sense of purpose, and the resources and support provided by their institution that helped them plan their careers and explore their sense of purpose. For this paper, we focus on students' experiences in the physics department and how they perceive the departmental community. Because the influential characteristics of a particular community of practice can often be identified when contrasted with another, we examine the experiences of double majors in physics and other disciplines. While many of the participants are double majors, in this paper, we chose two case study subjects: Julia (physics and education) and David (physics and mathematics). Julia and David were chosen because they clearly articulated their contrastive experiences in their primary and secondary departments. Julia is satisfied in her career as a physics high school teacher three years after graduation. David is currently deciding what happens next after his upcoming graduation as he is interested in both teaching and research. Julia and David share a mutual passion for physics and teaching: they are both looking for ways to use their acquired knowledge and skills to help the younger generation develop their scientific and critical thinking skills.

Each 45-minute interview (conducted over Zoom) had two interviewers (one primary, one secondary) and one participant; the interviewers were unaffiliated with the urban institution. The analysis began by watching Julia and David's interviews to locate statements relating to their experiences in their primary and secondary majors. Then, we iteratively paid attention to nuances in discourse pertaining to mutual engagement such as doing research, building relationships with peers and faculty, attending conferences, etc. For example, statements such as "I feel connected, I have a good relationship with faculty" gave us evidence of a strong sense of belonging to the community. In contrast, "I don't really talk to advisors, we don't have great relationships" conveyed a weaker sense of belonging to the community. Discourse analysis helped us identify what students and faculty do together in each department to grow their interest in each field, leading us to compare and contrast students' sense of community among their affiliated departments. The analysis was collaboratively discussed until consensus was reached among 4 researchers.

Analysis and discussion

Sense of mutual engagement in the primary department

A central part of students' sense of community is the mutual engagement they feel in the classroom. Classes, both lecture and lab, included strong group work components and students *"[worked] through almost every assignment together"* (Julia). Collaborations among lab partners were highly encouraged and students relied on each other to *"develop your answer or talk about what was wrong, how to fix this"* (Julia). These collaborations are not haphazard: the faculty do significant work to encourage and support students' mutual engagement. Faculty *"[initiated] the group work when we were struggling together"* (Julia), and helped *"[establish] the relationship throughout the lab groups"* (Julia). These intentional choices made by faculty foster people to "*give each other academic support, and there is an interconnectedness"* (David) in the department, which creates a supportive learning environment around coursework in the community.

These collaborations continue outside the classroom and specific class activities. The physics department offers students opportunities to do research, invites students to attend seminars, and encourages engaging beyond the scope of a departmental community by "*sending useful things like career programs, conferences, just little things but give [students] opportunities to have a wide thought"* (David). Being engaged in doing research with faculty can increase students' interest and motivate students to pursue physics in the long term as they "*enjoyed the type of research that [physics faculty] were doing. That's part of why [students] stay in the field"* (David). In addition to doing research, attending a national STEM conference (SACNAS) or national professional association (SPS) promotes joining a communicative environment to exchange information with other peers outside the class since these events "*put a lot of networking experiences, colloquia, or advice in grad school, how to effectively communicate in conferences"* (David). This sense of support for connections to the outside world helps students feel more connected within the local physics community.

Another defining factor of mutual engagement in the physics community is the close relationship between faculty and students, in which faculty become strong sources of support for students for both academic and career guidance. For instance, *"[Dr. D, a prof] set an example as a woman in physics", "had a big influence"* on what Julia is doing right now, and also "*helped [her] to figure out direction*" in her life. Similarly, David talks with both Dr. D and the department chair about his future and career path, noting that the chair is "*really supportive and helpful thinking about the career"*. Physics faculty's encouragement of interactions inside the classroom, outside the classroom and at wider scientific events makes students perceive faculty as approachable and supportive of students' current and future success, which fosters a sense of close-knit community among students and faculty.

The mutual engagement among students and faculty in the physics department has been strongly influential in fostering a sense of community. Not only do faculty teach physics courses, but they also immerse departmental culture into their instructional practice such as encouraging students to work in groups, encouraging participation in research, and sending useful information for scientific events. Based on that, both Julia and David have constructed a strong sense of community in the physics department. As David says, "*[we] all know what everybody else is doing, [all] know what faculty are doing, what graduates are doing, it's interconnectedness. [They] acknowledged about each other, and anybody in that"*.

Comparison with the secondary departments

It is important to note that Julia and David are both central participants in the physics departmental community. In contrast to their primary major, both Julia and David feel disconnected from the communities from their secondary majors. A lack of assigned group work outside of the education classroom makes students work more individually without relying on classmates to complete assignments. *"Outside of the class, there was no group work to do so [it'd] be writing papers, doing reading"* (Julia, education). Secondly, *"[her] academic advisor wasn't helpful"* (Julia) in helping students think about career choices. Julia *"didn't talk to [her advisor] much besides choosing classes"* and *"didn't have a great relationship with them as [she] did with [her] physics professor"* (Julia). In addition to this, while the physics department sent out many emails about job opportunities, graduate school application, writing effective CVs, etc., *[students] have never received the same emails about conferences or useful tips of things"* (David) in mathematics to support their understanding of what is happening in the field. The disconnect between department, faculty and students can result in a lack of essential support in growing students' interest, which leads to a reduced sense of belonging to the field. Lastly, research in the mathematics department feels less available to students. Contrasting with physics where "*[people] do research, talk about research, in math it doesn't really happen"* (David). Instead, *"the department looked more focusing on coursework"* (David). These three factors -- low group work outside of the classroom; the disconnect between department, faculty and students; and inaccessible research -- explain why students feel less sense of community in their secondary departments.

We don't want to claim that the secondary departments lack supportive community. From our data, it could be that those other departments don't have a strong sense of community among students; but it could also be true that these two students are peripheral to the communities of practice in their secondary departments, and therefore do not feel a strong sense of community and mutual engagement. From these two case studies, we cannot distinguish these two interpretations of their secondary departments.

Alternative explanations

There may be other explanations as to why students are more likely to feel a stronger sense of community in the physics department. We provide such explanations and then argue back to defend the physics department as a strong CoP based on mutual engagement between faculty and students. Firstly, it could be true that the unique nature of physics requires collaboration. Physics solves many complicated problems; therefore students need to work together collaboratively to develop solutions which lead to a stronger sense of community. However, it is worthwhile to mention that math and physics are similar in nature. Both are STEM disciplines that require a significant amount of problem solving, and math is the language through which physics is done. Hence, the content itself in each discipline is not a discerning attribute of the CoP development. Secondly, the small size of the classroom itself might be a factor why everyone knows each other. However, at this institution, physics and mathematics classes are similar in size, and physics and education also *"have about the same size hmm education cohort and physics cohort"* (Julia). Size of the classroom, therefore, does not directly affect the connection among members in the community. Overall we suggest that a strong sense of the physics community from Julia and David is not affected by the content of the field or the size of the classroom, but rather affected by pedagogical choice of physics faculty and how faculty merged departmental culture into instructional practice.

In this paper, Julia and David feel a stronger community connection in their primary department (physics) than their secondary departments (education and mathematics) because of the activities that faculty and students mutually do together. However, our claim is based on perspectives of two students only which may not fully reflect the whole culture of each department. Future work will need to expand data and look more into other components of the CoP framework in order to examine whether our claim still holds or not.

Conclusion

These double-majored students have a strong sense of community in the physics department, but not in their education and math departments. From our narrated analysis, we conclude that the content of each discipline or classroom size do not affect the establishment of CoP. The strong physics community mainly results from the pedagogical choices of physics faculties who merge the departmental culture into their instructional practice to support students' engagement in the community such as strongly encouraging group work, making research approachable, and encouraging students to attend scientific events. A strong perceived physics community enables students to engage in authentic practices of a physicist which can result in physics identity development (Close et al., 2016; Irving & Sayre, 2014). Our findings suggest that departmental culture should be structured to provide students with more opportunities to connect with classmates outside of the classroom, to work with faculty through research, and to broaden the relationships with people in the field by attending conferences. Future work will continue to examine the sense of community of other participants as well as explore how students prepare for future careers based on their sense of community in the physics department.

Reconciling Structuring Collaboration and Student Agency

Moegi Saito, Shinya Iikubo

Abstract: Advancement in supporting knowledge construction creates deeper problems on how to reconcile structuring collaboration with promoting student agency. In order to provide a case study for these problems, we used an instructional method, the "Knowledge Constructive Jigsaw", as an external macro-script in a science lesson and analyzed pre-, post-lesson answers and a 15-minute discussion by three seventh graders. We captured knowledge sharing and individual construction by adapting a framework, a "function mechanism hierarchy", and a dual-unit analysis at a group and individual level. The results indicate the reconciliation, that is, the students shared knowledge pieces while constructing their own knowledge, for which a coupling between the coarse-grained script and well-organized materials appeared responsible.

Introduction

As the learning sciences advances its refinement in supporting collaborative knowledge construction, it poses deeper problems on how to reconcile *structuring collaboration* with *promoting student agency*. This paper provides a case study to show that structuring collaboration towards the teacher's expected outcome does not necessarily hinder but promotes student agency, or the self-organizing character of knowledge construction. Along with the conference theme of "reflecting the past and embracing the future," we reflect upon a discussion between two approaches of scripted collaboration and Knowledge Building (Bereiter et al., 2017), provide our case study wherein three junior high school students deepened their understanding in their own way and also successfully shared knowledge as a group in a science lesson, and examine which elements of lesson design are responsible for reconciling the two aspects of knowledge construction for future practices.

In the discussion above, experts in Knowledge Building welcomed a change in the views of *scripts* as *rigid, prescriptive cognitive structures* to *flexibly adaptive group supports* for facilitating the use of learners' internal scripts, while experts in script theory adopted more socio-cognitive views into classroom learning (Vogel, Wecker & Kollar, (2017). Thus, the notion of flexibility, which Dillenbourg & Tchounikine (2007) once analyzed conceptually, needs to be examined in actual socio-cognitive processes. For example, setting a common task and providing materials may constrain learners' interactions into a corridor towards expected outcomes, but in reality, each learner may construct her or his own knowledge through the interaction. In order to reveal such an intricate relationship between constraint and self-organization, we need to collect data from a lesson wherein learners are motivated to share knowledge to achieve a common goal and analyze learning processes by mapping their writings and utterances onto a knowledge framework and using both units of analysis of the individual and the group.

Instructional method: Knowledge Constructive Jigsaw

We take group learning in the lesson conducted by the "Knowledge Constructive Jigsaw" (hereafter "KCJ") method (Miyake, 2013) as an example. The KCJ consists of five learning activities: (1) writing an answer to the day's given problem, (2) an expert-group activity which allows each individual learner to accumulate pieces of knowledge relevant in solving the problem, (3) a jigsaw-type activity where learners from different expert groups get together to exchange and integrate the pieces of knowledge and form an answer, (4) a crosstalk activity where the learners exchange their ideas for solutions, involving the entire class, and (5) writing down an individual answer again to the same problem. This method distributes knowledge among the learning partners in Step 2 for integration in Step 3; however, it places greater emphasis on the role of a shared "problem" for knowledge construction by adding Steps 1 and 4, as well as that of the conceptual changes of each individual by adding Steps 1 and 5. The method is considered to be an *external macro-script* like the Jigsaw (Dillenbourg & Jermann 2007), and we do not predict how the script is enacted in a particular situation as it is coarse-grained enough to allow learners' self-organization of knowledge and discussion.

Analytical method: Function-mechanism hierarchy and dual-unit analysis

The series of activities above enables us to compare students' dialogues with writings: for example, the former in the jigsaw activity of Step 3 with improvements in the latter from Step 1 to Step 5. We bring in two analytical methods to take advantage of this feature: a "function-mechanism hierarchy (FMH)" (Miyake, 1986) and a dual-unit analysis. The FMH is a hierarchy that consists of two types of knowledge: function and mechanism, which is suitable in clarifying the detailed structure of the lesson and knowledge construction by the learners. The dual-unit analysis is to analyze the same data using two units of analysis: the individual and the group. Saito and Miyake (2011) demonstrated that, when analyzing a collaborative process sequentially, the selection of knowledge pieces, time of reference and order vary from learner to learner; however, when analyzing it in an aggregated way, most of the pieces are referred to by most learners while the rest are referred to by only a few learners.

Research questions

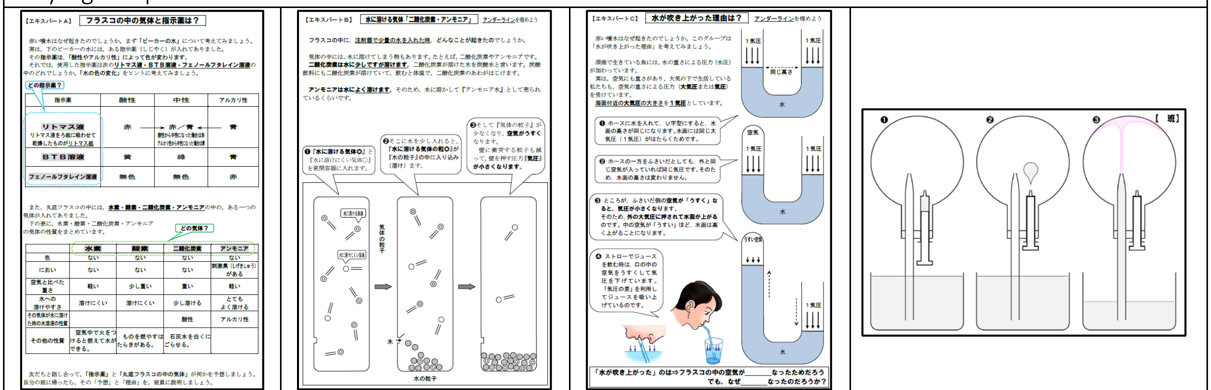
A combination of the instructional method and the two analytical methods enables us to capture a convergent, knowledge-sharing aspect constrained by the macro-script and a divergent, individualistic knowledge-construction aspect that goes beyond what is given in the situation. We predict that a set of the "problem (jigsaw task)" and "expert materials" strongly constrains students' knowledge sharing, especially when knowledge pieces are explicitly presented and hierarchically organized, while the students differ from each other in knowledge construction by connecting and weighing particular pieces, especially when fewer prompts for discussion or scaffolds for writing are presented, that is, *unscripted*. Thus, our first research question is, "Are the knowledge pieces of expert materials successfully shared among the three students through the jigsaw activity?" and the second one is, "Do the three students differ from each other in the number of references to knowledge pieces and relation-making among them both during the jigsaw conversation (Step 3) and post-lesson writings (Step 5)?"

Method

A veteran junior high school teacher, a partner teacher in the authors' project, conducted a KCJ lesson in Grade 7 science ("Generation and the nature of gas") for 19 students. The teacher demonstrated an experiment in which a transparent solution in a beaker was vigorously pumped up through a glass tube into an upside-down, sealed, round-bottom flask, which turned red when he injected a small amount of water into the flask with a syringe. He posed the day's problem and each student wrote his or her answer on an *unscripted* worksheet. Then, the students engaged in the activities of Step 2 through Step 4 in 50 minutes. The teacher prepared materials for the expert activity and a whiteboard for the jigsaw activity, from which he expected the answer below (Figure 1).

We handed out a headset microphone and IC-recorder to each student, collected voice data, and transcribed it by hand for the analysis. We also collected students' answers before and after the lesson to analyze whether they referred to the points shown in Figure 1. Out of six jigsaw groups we chose one group which consisted of Alpha, Bravo and Charlie (assumed names which mean Alpha was assigned expert material A, Bravo for B, and Charlie for C). We chose this group since they proposed high-quality explanations at the level of

Day's given problem "How did this red fountain occur? What is the mechanism?"



A: Gas and indicator | B: Solution in water | C: Solution blow-up | Whiteboard for the Jigsaw activity

An expected answer should include the four points below:

1. At the onset, "ammonia gas" was injected into the flask; "phenolphthalein solution" into the beaker (Material A).
2. When the water was injected into the flask with the syringe, the ammonia gas, being very soluble, melted into the "ammonia water" and the air pressure in the flask was reduced (B).
3. When the pressure in the flask was reduced, the water in the beaker pushed by the outside atmospheric pressure rose up the glass tube and a fountain occurred (C).
4. Since a phenolphthalein solution was in the water, entering the flask from the beaker, it reacted with the "alkali" of the ammonia water and the fountain became red (A).

Figure 1. Expert materials, worksheet for the jigsaw-type activity and expected answer for the targeted lesson.

molecular motion in Step 4 and all of them wrote the four points in the expected answer in Step 5.

Figure 2 shows the FMH for the lesson. The functions are shown in circles as F, indicating knowledge pieces of facts and phenomena. The mechanisms are indicated in rectangles as M, describing explanations of "how and why that happens" by connecting the functions with each other. The mechanism of the red fountain (F0-1) can be explained by the combination (M1) of the water injection (F1-1), ammonia gas (F1-2) and phenolphthalein solution (F1-3). Yet, if someone questions why the transparent materials turned red, the answer requires another level of explanation such as the chemical one at level 2. Likewise, the function at level n requires the mechanism at level n+1 in a repeated way. By mapping pieces of information contained in each expert material onto the hierarchy with bold alphabet letters A, B and C (when it was implied, they were indicated by letters in parentheses), you can see that most knowledge pieces were explicitly presented and hierarchically organized with each other.

We also analyzed the students' pre and post lesson answers and the 15-minute jigsaw dialogues using FMH: first, dividing each sentence into *content word* and *function word* (connectives, pronouns); and second, mapping the former on the framework as referring to the knowledge pieces and the latter as relation-making among the pieces. The total number of utterances of the group was 596.

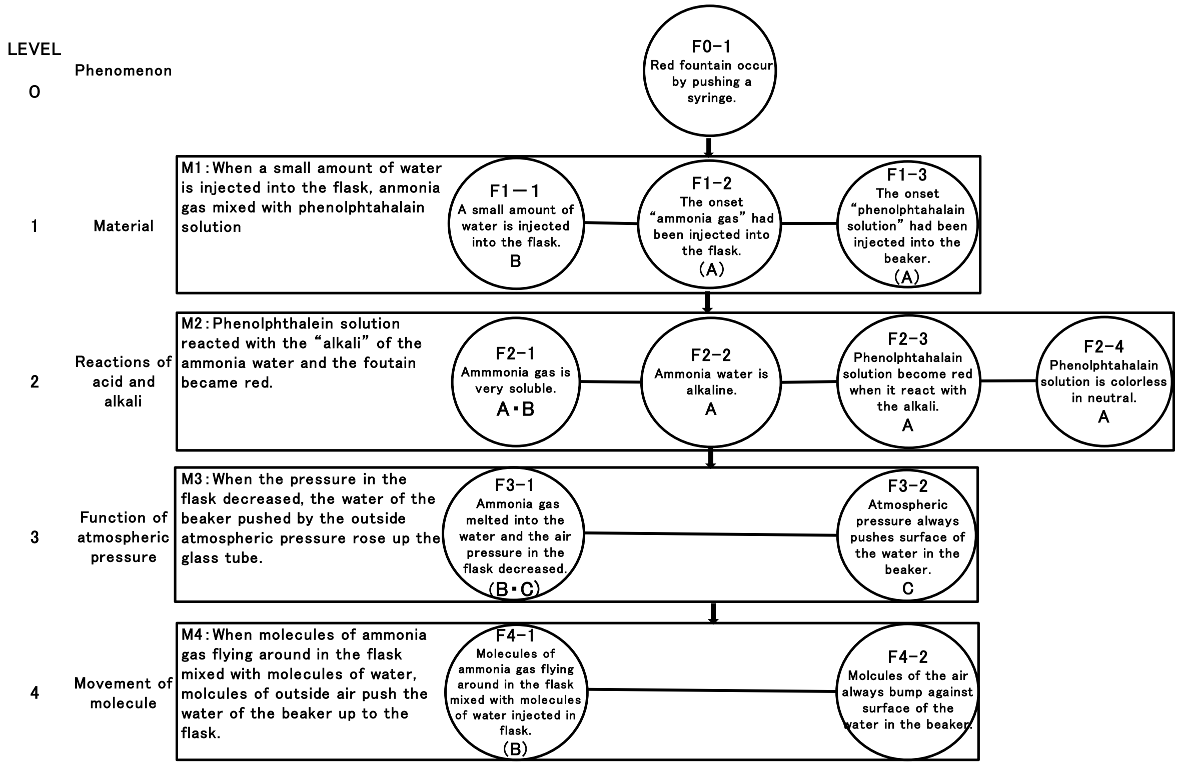


Figure 2. Function-mechanism hierarchy for the red fountain problem

Results and discussion

When we analyzed the pre- and post-lesson (Steps 1 and 5) answers of 12 students whose worksheets were collected, we found that their coverage rate of the four points in the expected answer improved from 3.2% in Step 1 to 87.5% in Step 5. Despite the fact that the lesson was conducted at the beginning of the unit and the students knew little about the content, the improvement was big enough to conclude that the class achieved the goal.

Table 1 shows the result of the detailed analysis of the target group. The column "Knowledge" indicates knowledge pieces shown in Figure 2, and the columns of the "Pre-lesson answer", "Jigsaw activity" and "Post-lesson answer" represent whether each student referred to, repeatedly referred to, or linked each piece with another. If we look at Table 1 in an aggregated way, eight out of 12 knowledge pieces were shared among the three students through the jigsaw activity, and seven out of the eight pieces referred to were utilized in the post-lesson answers. Considering the fact that they referred to only one knowledge piece in the pre-lesson answers, we can say that all the members improved their understanding towards a common goal by sharing the knowledge pieces. Taking a closer look at Table 1, however, individual differences are revealed in both the jigsaw activity and post-lesson answer. Alpha referred to nine knowledge pieces during the jigsaw activity and constructed her post-lesson answer by connecting the pieces about the gas and indicator (Levels 1 and 2); Bravo referred to nine pieces and constructed her explanation around two points such as the injection of water (F1-1) and the reduction of pressure (F3-1, F4-1); Charlie referred to ten pieces and broadened connections across all levels in his post-lesson answer.

The results indicate that while the knowledge pieces of the expert materials were successfully shared among the students through the jigsaw activity, they differ from each other in the number of references to knowledge pieces and relation-making among them from the jigsaw activity to post-lesson answers, as if they had walked down the corridor towards expected outcomes while constructing their own knowledge through interaction with others. It is implied that the constraint caused by the macro-script makes diversity and agency flourish in finer levels of knowledge construction. In this particular lesson, a coupling between well-organized materials and coarse-grained scripts without strict control or guidance appeared responsible for reconciling structuring collaboration with student agency. Yet, we do not intend to generalize this result from only one case, especially because another case under analysis suggests that a pattern of role exchange among member influences both the convergent and divergent knowledge construction process. Rather, we would like to claim that not only controlled experiments but also in-depth analyses of knowledge construction processes contribute to clarifying the intricate relations between constraint and self-organization and designing lessons for deeper learning.

Table 1: Reference and link of knowledge of three students in the lesson

Knowledge	Pre-lesson answer			Jigsaw-type activity			Post-lesson answer		
	Alpha	Bravo	Charlie	Alpha	Bravo	Charlie	Alpha	Bravo	Charlie
F1-1(B)	○	○	○	○+	◎+	○+	○	○+	◎+
F1-2(A)	—	—	—	◎+	◎+	◎+	◎+	○+	○
F1-3(A)	—	—	—	◎+	◎+	◎+	◎+	○+	○+
F2-1(A,B)	—	—	—	◎+	◎+	◎+	◎+	—	◎+

Probing Biology Teachers' Disciplinary Literacy through their Adaptation of a Research Article

Moriah Ariely, Weizmann Institute of Science, moriah.ariely@weizmann.ac.il
Ravit Golan Duncan, Rutgers University, ravit.duncan@gse.rutgers.edu
Anat Yarden, Weizmann Institute of Science, anat.yarden@weizmann.ac.il

Abstract: Disciplinary literacy framework is concerned with the unique skills and strategies of reading and writing in a specific discipline. Adapted primary literature (APL) refers to an educational genre specifically designed to enable the use of scientific research articles in high school. APL articles represent the structure, linguistic norms, epistemic standards and content found in research articles, and can therefore be used to promote disciplinary literacy. However, very little is known about how teachers adapt research articles, or how they justify decisions they make regarding these adaptations. In this study we analyzed in-service teachers' justifications for decisions they made when adapting a scientific research article for their students, in the context of a methods course. Our research provides a "window" into teachers' understanding of disciplinary literacy aspects, and provides critical insights that can be further used to develop better teacher professional development programs and teacher education.

Introduction

Reading scientific texts has become accepted as one of the major required practices to become literate in science (NRC, 2012). However, although current learning standards foreground advanced literacy learning in the subject areas (e.g., the United States *Common Core State Standards*), the majority of students do not progress much beyond basic reading skills (Goldman et al., 2016). Moreover, the vast majority of texts that students read in science classroom are from textbooks, popular research from the media or review articles from the internet. These texts often do not reflect the core attributes of scientific reasoning and are antithetical to the epistemology of authentic science (Ariely et al., 2019; Chinn & Malhotra, 2002).

Disciplinary literacy (Shanahan & Shanahan, 2008) emphasizes the way of thinking in a discipline, including what is important to pay attention to, what counts as evidence for an argumentation, what level of confidence the field has in the knowledge it produces, how texts are organized, constructed, etc. (Shanahan & Shanahan, 2020; Shanahan & Shanahan, 2008). These practices are inherently epistemic, based on ideas about what kinds of knowledge are valued (Duncan et al., 2018).

There are many challenges in integrating disciplinary literacy skills into science classrooms. For example, many science teachers know the content of their disciplines, but they may know only implicitly its literary processes (Hynd-Shanahan, 2013). As a result, many teachers lack the knowledge about the vital role that literacy plays in enhancing science learning, and they fail to mentor their students in the necessary literary practices that would help them read in science (Osborne, 2014). Teachers need a sophisticated understanding of the nature of scientific texts, as well as how they are used authentically by the scientific community. Therefore, effective professional development is needed to help teachers learn and refine the pedagogies required to teach these skills (Darling-Hammond et al., 2017).

Engaging with adapted primary literature (APL) to promote disciplinary literacy

Adapted Primary Literature (APL) refers to an educational genre specifically designed to enable the use of scientific research articles in high school (Falk et al., 2008). PSL articles are adapted to match students' knowledge, reading abilities and cognitive skills, while retaining the authentic characteristics of the PSL article (Yarden et al., 2015), and the scientific language (Ariely et al., 2019). Since APL articles represent the structure, linguistic norms, epistemic standards and content (arguments, claims and evidence) found in PSL articles (Ariely et al., 2019; Yarden et al., 2015), these articles can be used to promote important aspects of scientific literacy that are harder to achieve using other text genres such as textbooks or popular articles.

Standards in the US and elsewhere require that science teachers shift the ways in which they support their students in learning literacy practices to a more disciplinary approach (NRC, 2012). However, there is little research about secondary science teachers' understanding of disciplinary literacy, or how they interpret and make sense of the epistemic and linguistic features of PSL articles. Research on pedagogies aimed at promoting advanced literacy skills are scarce, and mostly focused on ways in which teachers integrate disciplinary approaches and activities in their classrooms (Koomen et al., 2016). Moreover, while research on APL with students is very promising, there is hardly any research on teachers' engagement with APL.

Research goals and questions

Understanding teachers' justifications for decisions they make in the adaptation process is important because it illuminates what teachers notice, value, see as important for students to learn. Teachers' justifications may therefore provide insights into teachers' understanding of disciplinary literacy, and may shed some light on the challenges they face when asked to implement disciplinary literacy practices in their instruction. This knowledge is crucial for developing interventions for teachers that can help them foster disciplinary literacy among their students. Therefore, in this study we asked: What kinds of justifications do in-service biology teachers make when adapting a scientific research article for their students?

Methods

Research context

The context of this study is a four-weeks unit (8 hours) that is part of a 26 hours university level course for in-service biology teachers entitled "Science Literacy". The course aims to promote teachers' pedagogical and disciplinary knowledge by interacting with, and learning about disciplinary texts. In the 8 hours unit teachers were asked to adapt a PSL article for their students.

The article selected for adaptation was a short research article, published in a medical scientific journal. The article deals with the effect of pomegranate juice on serum Angiotensin Converting Enzyme (ACE) activity, and on systolic blood pressure in human patients (Aviram & Dornfeld, 2001). We found this article suitable for the teachers to adapt because the concepts and processes discussed in the article are largely aligned with the current high school biology curriculum. In addition, the article is short and relatively simple, allowing the teachers to adapt it within the time limits of the course.

Data collection and analysis

Twenty-one in-service high school biology teachers (with 5-20 years teaching experience) adapted the PSL article. All the teachers taught at public schools from various locations in Israel, and had a B.Sc. degree in biology. The writing sessions were collaborative in groups of 2-3 teachers (9 groups in total). The teachers were encouraged to reflect on their justification for changes they made to the article (omissions, additions), but also on justifications for leaving certain elements of the article as they were.

We collected a total of 265 justifications of features of the PSL text that teachers chose to change or retain in the adaptation process in their written artifacts at the end of the course. We classified the justifications according to their type to four main categories using a grounded analysis approach. A subset of the data (~20%) was validated by two additional researchers. The agreement on the categorization at the beginning was ~82%, and after discussion reached ~93%. Further elaboration on the categories is given in the Results section.

Results

The teachers' justifications included considerations along four dimensions: pedagogical, epistemological, content-based, and structural. We provide definitions and proportions of the categories, and examples of teachers' actual justifications in Table 1.

We found that out of all justifications (n=265), the majority (64.1%) were pedagogical, about a quarter (24.2%) were epistemological, and a few were content based or structural (8.3% and 3.4%, respectively). Since pedagogical and epistemological justifications are focused on students' needs and abilities (and less on technical features as was the case of structural or content-based justifications), we focus our analysis on these justifications.

Interestingly, we found that the majority of pedagogical justifications were in support of a *change* in the article; adding, omitting or changing the ways in which the information is presented in the original article. However, the majority of epistemological justifications were in support of *retaining* the way information was presented in the original article. This reveals a potential tension between pedagogical and epistemological justifications; in a sense one may come at the expense of the other. This tension was often apparent during the adaptation process as shown in the following examples.

In some cases, the teachers were less attentive to important epistemological features. For instance, rebuttals have an important role in argumentation, and in the PSL article chosen for this study, the rebuttals provided alternative interpretations of the results, and pointed out some of the research limitations. However, many teachers chose to omit rebuttals that appeared in the original article, and to leave only conclusions and evidence that support the claims made in the article, in order not to confuse the students' or to reduce the cognitive load (a decision with pedagogical justifications). In other cases, the teachers saw the importance of transparency of methods or results (a decision with epistemological justifications), but were less concerned with accurate and nuanced reporting of the methods or results. For instance, they often chose to remove important information about the sample, or to remove error bars, standard deviations, or to completely omit "messy" results that were less conclusive, in order to make the data representation less complicated and more straightforward for their students to interpret (a decision with a pedagogical justification).

We also found different distributions of pedagogical and epistemological justifications in different article sections. Although there were high proportions of pedagogical justifications in all sections, in the *Discussion* and *Methods* sections there were relatively more *epistemological* justifications (44% and 30% respectively), compared to the Introduction and Results sections (16% and 12% respectively).

Table 1: Categories of teachers' justifications when adapting an article for students

Categories of justifications (n=265)		**Examples (justifications appear in italics) & proportions out of all justifications**	
Pedagogical	Justifications focus on students learning needs and abilities. This includes justifications for adapting the text to match cognitive and reading abilities, and prior knowledge, creating learning opportunities, and promoting students' interest and motivation.	We omitted any information about polyphenol concentrations, *because we want to reduce the cognitive load.* We added a question about the graph *so that students could practice graph analysis.*	64.1%
Epistemological	Justifications focus on using the article as a model for learning about the scientific epistemology and reasoning. This includes justifications for including reliable processes, transparency of information presented in the text and different aspects of the nature of science.	We kept the information that the effect of the pomegranate juice may be secondary [to the antioxidant properties of pomegranate juice]. *It is important that students will be exposed to the uncertainty presented in the article, and that they get to know articles in which not everything is proven and certain.*	24.2%
Content-based	Justifications focus on the content of the article to create coherence and continuity within the text.	We omitted any information about rampiril [ACE inhibitor] *because it doesn't connect directly to the experiment presented in the [APL] article.*	8.3%
Structural	Justifications focus on the texts' structure, for technical reasons.	We separated the results from the discussion, *because this is the acceptable structure of a scientific article.*	3.4%

Discussion

In this study we provide a novel analysis of teachers' justifications for decisions they made when creating an APL article for their students in the context of a course assignment focused on promoting teachers' disciplinary literacy and the use of disciplinary texts in biology classrooms.

Our analyses show that teachers had two main types of justifications when it came to their teaching goals in the context of engaging students with a disciplinary text. First, pedagogical justifications, the majority of the teachers' justifications were pedagogical, aimed at adapting the text to match the students' abilities and needs. Second, epistemological justifications, which were aimed at providing opportunities to learn and reflect on different epistemological aspects of science, including the nature of reasoning and reliable processes. It should be noted, that the teachers in this study were explicitly taught about the epistemology of science and about the communicative role of different scientific text genres, which allowed them to create an APL and take epistemological considerations into account.

The fact that the teachers had many pedagogical justifications may not be surprising. However, a quarter of their justifications were epistemological, and although they were much less frequent than pedagogical ones, we believe that teachers' awareness of and attention to epistemological considerations is important and encouraging. In addition, the fact that the *Discussion* and *Methods* sections in the adapted article had relatively more epistemological justifications suggests, that these sections that are usually under-represented in classroom texts, may provide the teachers opportunities for integrating more epistemic and disciplinary features that can be taught using the APL article.

The teachers' decisions and justifications throughout the adaptation process revealed a tension between pedagogical and epistemological justifications. On the one hand, teachers wanted the text to match their students' prior knowledge and abilities, therefore, they made numerous *changes* throughout the article. On the other hand, the teachers wanted the text to remain epistemologically authentic, so that it will reflect the scientific discourse and disciplinary norms. In this case the teachers *retained* different features in the article. This tension often resulted in teachers abandoning important epistemological features of research articles such as rebuttals for claims in the article, and data that are relevant to the argument and to the evaluation of evidence. This provides important insights about the role of different justifications when creating an APL article for students, and specifically pedagogical and epistemological ones. If all justifications were epistemological, we would end up with a PSL article, not suitable for high school students. If all justifications were pedagogical, the texts might end up resembling a textbook or a popular article. Therefore, the results from this study emphasize the importance of having *both justifications* when creating an APL article, and the need to help teachers develop useful heuristics for balancing them.

Implications

Although teachers were able to notice epistemic features that are essential for building the argument in the article, in some cases they were less attentive to these features, or to their epistemic role (for example, omitting rebuttals from the Discussion). In other cases, teachers valued some aspects of scientific epistemology more than others. These decisions that teachers make highlight the tension between pedagogical and epistemological justifications. Therefore, one implication for teacher education programs is to focus on helping teachers to understand the article's argumentative structure. This includes understanding the role of each section in building the argument, and the importance of epistemic considerations relevant to the scientific argument as they pertain to each section.

Another implication concerns the selection of text materials for science teaching. Shifting to a more disciplinary approach requires that teachers make disciplinary texts available to students, and provide guidance and interpretation of particular text features, and specific disciplinary reading strategies (Shanahan & Shanahan, 2020). Nevertheless, texts will only support disciplinary literacy to the extent that the texts are appropriate to the purpose and methods of the discipline. Thus, the content should meet the demands of the curriculum, but also include the specialized text features of the discipline (Shanahan & Shanahan, 2020). This calls for a careful consideration of texts and materials used for science education, which should include texts that reflect more authentically the scientific reasoning and communication.

What Can Automated Analysis of Large-Scale Textual Data Teach Us about the Cultural Resources that Students Bring to Learning?

Raquel Coelho, Stanford University, rcoelho@stanford.edu
Alden McCollum, New York University, amccollum@nyu.edu

Abstract: In this paper, we explore what the application of data science techniques to student-produced texts will reveal about the cultural resources that historically-othered learners bring to formal learning environments. We analyze 14,526 essays written by high school students in Brazil, present preliminary findings, and consider the ways this type of analysis might support teachers' design work in ways that are sensitive to variation in students' experiences.

Keywords: cultural resources, everyday practices, structural topic modeling, textual data

Introduction

Students bring many cultural resources to school with great potential to support participation in the cultural practices of academic disciplines (Nasir, Roseberry, Warren, & Lee, 2006). Exemplifying "cultural resources" are everyday bodies of knowledge, skills, and abilities (Moll, Amanti, Neff, & Gonzalez, 1992), ways of engaging in activities (Gutierrez & Rogoff, 2003), discourse practices (Lee, 1995), forms of reasoning (Nasir, 2005), values (Pea & Martin, 2010), and complex beliefs (Bang & Medin, 2010) developed in the richly generative cultural practices of the multiple communities in which students participate (Lee, Nasir, Pea, & de Royston, 2020). There is growing learning sciences consensus that educators should build upon their students' cultural knowledge, especially that of those historically marginalized for multiple facets of their identities. Building on cultural knowledge should prove to support academic learning (Nasir et al., 2006).

In an effort to counter deficit perspectives that other certain groups, a number of theoretical frameworks emerged in the 1990s, providing concepts and tools to support the design of robust learning environments that are responsive to variation in students' experiences. These include, for example, Culturally Responsive Teaching (Gay, 2018), Culturally Relevant Pedagogy (Ladson-Billings, 1995), Funds of Knowledge (FoK: Moll et al., 1992), and Culturally Sustaining Pedagogy (Paris, 2012). Despite differences in critical commitments and emphases, these frameworks share a consequential common assumption: that by recruiting the cultural resources that students have developed through everyday experiences, teachers will be better able to engage those students in learning in ways more immediately relevant to students' lives. A growing body of empirical research documents the connection between classroom practices that capitalize on historically-marginalized students' lived experiences and their engagement and learning across disciplines (Aronson & Laughter, 2016).

One of the most lasting frameworks, the FoK approach, pays special attention to families' social histories and labor activities, and provides a pragmatic toolkit for teachers to build knowledge of students' cultural resources and to then use that knowledge to support students' formal learning. The original approach suggests that teachers visit students and families and document in ethnographic observations and interviews the knowledge and skills available to students via households' everyday practices (González et al., 2005). Broader conceptualizations of FoK (Hogg, 2011), along with related frameworks like Third Space (Moje et al., 2004) and Funds of Identity (Esteban-Guitart & Moll, 2014) have sought to address some of the FoK approach's limitations, such as the exclusion from analysis of other communities in which students themselves choose to participate and the reliance on ethnographic analysis. While acknowledging that the idea is not new, Funds of Identity researchers have proposed using student-produced artefacts as a way of obtaining empirical information about students and then crafting connections between curricula and students' contexts (Llopart & Esteban-Guitart, 2018). Such use has most often been proposed in the context of a single classroom, using artefacts collected by individual teachers.

Here we explore whether a similar idea might be leveraged on a broader scale. Specifically, we examine what the application of data science techniques to student-produced texts reveals about the cultural resources that historically-othered learners bring to formal learning environments. While teacher-initiated qualitative-only approaches are an excellent option when feasible, it could serve the field well to complement such approaches with big-data-backed approaches so as to allow for investigation that is both broad and deep. As data collection technology evolves, there are increasingly many data sources available to researchers, and the insights drawn from such data can and should be used to support teachers in building knowledge about their students.

Taking up that project, we use Structural Topic Modeling (STM) to identify the topics (and extract essays associated with them) that students who have historically been marginalized in Brazilian society choose to write about. Following cultural-historical activity theory (Cole & Engestrom, 1993), we accept the premise that all acts of writing are situated, and that writers always recruit cultural resources that are made available to them to appropriate and internalize through their participation in the cultural communities to which they belong. While other pressures, such as the political, historical, and cultural context might partially shape students' choice of topic, those choices are still in large part driven by their interests, knowledge, and experiences. We then examine whether and how those topics differ geographically (state by state, urban vs. rural) and/or by year written. We chose those particular lines of comparison due to constraints on available demographic data, yet they are by no means the only potentially revealing ways of delimiting micro- and macro-communities. Variations in cultural resources are rooted in the practices of the multiple communities in which students participate – practices that are layered and vary over time. Ultimately, we ask: What insights about students' cultural resources can we gain from large-scale textual analysis?

Background

Brazil's education system is (unofficially) segregated along both racial and class lines. Public school students account for roughly 90% of high school students in Brazil (BRASIL, Inep, 2019). High quality private schools remain largely the purview of white and relatively affluent students, while most non-white, low-income students attend public schools. As such, research on public school students in Brazil can provide insights into the education of students who have historically been marginalized in Brazilian society.

The Portuguese Language Olympics (PLO) is a biannual writing contest for public school students across Brazil. The competition invites 5th to 12th graders nationwide to produce poems, literary memoirs, chronicles, opinion articles, or short documentaries about the places they live. The contest has a very broad reach. In 2016, for example, 4,874 of Brazil's 5,564 municipalities participated. Further, the reach is not skewed geographically; both the urban/rural makeup and the regional distribution are fairly similar to Brazil's wider demographics. Given the PLO's reach, student submissions to the PLO serve as an excellent source of large-scale textual data that could inform educational practices. The current project capitalizes on this potential. Specifically, the dataset used in this study consists of the collection of all opinion articles written by PLO participants between 2012 and 2016 who advanced to at least the municipal level. This includes a total of 14,526 essays, for each of which a student was asked to write a persuasive essay articulating their view on a polemic topic in the place they live.

Data analysis

The data were analyzed using Structural Topic Modeling (STM), an unsupervised machine learning algorithm (Roberts, Stewart, & Tingley, 2014) that takes in a set of textual data to (1) identify latent topics within each text, and (2) estimate the relationship between those topics and information about each text (topical prevalence covariates). A topic is defined as a mixture over words where each word has a probability of belonging to a topic, and the sum of word probabilities for a given topic is one. Each text is defined as a mixture over topics, and the proportions of all the topics across any given text always sum to one. In the present study, STM is useful for discovering what students write about and for estimating the relationship between students' characteristics and how much attention they give to particular topics.

After estimating a structural topic model with 14 topics (STM requires users to specify the number of topics), we labeled each topic based on the words most highly associated with it as well as the actual essays associated with each: "Challenges Schools and Students Face," "Public and Private Investment," "Economy and Unemployment," "Tourism and Natural Attractions," "Life in the Countryside," "Violence, Crime, and Drug Abuse in Youths' Lives," "Mobility Issues," "Land Rights Issues," "Politics and Elections," "Water Scarcity and Pollution," "Public Health Services," "Agriculture," "Cultural Heritage and Festivities," and "Local Community." We selected students' states, school locations (urban or rural), and essay years as topical prevalence covariates to be studied and then estimated expected proportions of essays belonging to each of the 14 topics as a function of these covariates. Preliminary results are discussed below.

Preliminary findings

What do students write about in their essays?

Of the 14 topics, some were more prevalent than others. "Economy and Unemployment" was the most prominent topic, represented in 11% of the corpus. The least prevalent topic, "Land Rights Issues," was represented in 3% of the corpus.

What is the relationship between covariates and the expected proportion of an essay that belongs to a topic?

State

For 10 of the 14 topics, the proportion dedicated to a given topic appears to vary by state. Further, with few exceptions, the percentage of essays dedicated to each of the 14 topics appears more similar within regions than between them. Initial comparison with the reference category revealed statistically significant differences (*ps* < .05) in topic proportion in student essays between states.

Urban vs. Rural

Certain topics (e.g., "Agriculture," "Environmental Issues," and "Local Community"), were more prominent in rural students' essays, while others (e.g., "Public and Private Investment" and "Cultural Heritage and Festivities"), were more prominent in urban students' essays. Other topics were observed across both urban and rural samples but still leaned either urban (e.g., "Violence, Crime, and Drug Abuse in Youths' Lives") or rural (e.g., "Land Rights Issues"). Still other topics, such as "Challenges Schools and Students Face," and "Life in the Countryside," were more evenly represented in both urban and rural students' essays. Excepting three topics ("Challenges Schools and Students Face," "Life in the Countryside," and "Land Rights Issues"), further analysis confirmed statistically significant differences (*ps* < .05) in topic proportion in student essays between rural and urban areas.

Year

Finally, with respect to year, 10 topics were found to vary statistically significantly by year (*ps* < .05). Five topics' prevalence increased from 2012 to 2014 and/or 2016: "Challenges Schools and Students Face," "Public and Private Investment," "Violence, Crime, and Drug Abuse among Youth," "Mobility Issues," and "Cultural Heritage." Conversely, five topics' prevalence decreased from 2012 to 2014 and/or 2016: "Economy and Unemployment," "Tourism," "Life in the Countryside," "Politics," and "Agriculture."

Discussion and directions for further research

Our results reveal that students encompass a wide range of topics in their essays, which reflect a collective body of shared and unique experiences and knowledge resources that teachers could learn from and tap into when designing culturally-adaptive learning experiences. The states and areas where students live appear to influence how much students write about each of the topics identified in the corpus. Some topics show little state-based variation, suggesting that they are widely-shared concerns across Brazilian youth. By contrast, topics that seem to reflect more locally-salient experiences exhibited wider state-based variation. The same patterns were observed along urban vs. rural lines. Finally, the year in which students wrote their essays also played a role in how much they discussed certain topics. Through the topics they write about, we can gain insight into some of students' economic, social, political, and environmental *concerns*. Students demonstrate *knowledge* of issues and priorities in their communities. They convey *difficult knowledge* (Zipin, 2009) that reflects challenging existential conditions in which they find themselves as members of young and often marginalized populations in Brazil. Further, in choosing a topic, a student *positions* him-/herself as someone who cares about that specific issue.

A closer look at the essays helps us understand what kinds of insights can be gained that could aid teachers in understanding the communities students participate in, the practices they engage in, and the cultural resources they thereby develop. For example, in one essay with an estimated 50% dedicated to "Challenges Schools and Students Face" and 35% to "Agriculture," the author describes the difficulties of balancing school obligations with work on bean plantations. She asserts that data show that "50% of high school students drop out of school to harvest beans," highlights the economic importance of bean crops to students' families, and details the struggles faced by students who work the bean harvest, arguing that schools should consider "students who are unable to reconcile study with work" and create initiatives that make it possible for them to study while also assisting their families with the harvest. From this essay, we can glean information about several communities the author participates in (students who work, bean harvesters) and activities he/she engages in (growing, harvesting).

We believe that such insights about students' topics constitute a valuable resource that cries out to be leveraged to improve learning in formal instruction. This could be the raw material for teachers to design learning environments that build on students' cultural resources. Further, teachers could use such insights and the essays themselves to spark student learning dialogues (Wells, 1999), prompting them to think critically about the communities to which they do or do not belong, as well as about why students from their region might write about a given topic more often than students from another. Such conversations have generative potentials for helping teachers elicit a multitude of cultural resources, not only those related to knowledge contents.

The findings presented thus far are only the beginning. Moving forward, our goal is to work with science, math, and language arts teachers in Brazil to study how they might utilize the topics uncovered by data science in conjunction with an exemplary corpus of essays in designing culturally-informed learning experiences.

The Inseparability of Identity and Knowledge Construction in Humanistic Knowledge Building Communities

Liat Rahmian, University of Haifa, Israel, liatr123@gmail.com
Yotam Hod, University of Haifa, Israel, yhod@edu.haifa.ac.il

Abstract: This research builds on the idea that learners' identities and the knowledge they advance are inseparable. Our aim is to examine how fostering learners' identities can shape the way they view knowledge, suggesting that instructional environments should attend to identity development as they should to epistemic goals. In this paper, we first explicate the theoretical grounds underlying the inseparability argument. Next, we describe the special design of a learning environment, called a humanistic knowledge building community, to explain how the interconnectedness of identities and knowledge can be supported to become an intentional facet of the knowledge building endeavor. Our findings and the resultant conceptualization extend broad views of learning that consider ways-of-knowing and being as intertwined, to show how the actual ideas that learners advance are also deeply entrenched with their ways-of-knowing and being. Such accounts have been described in learning sciences literature, but have not been empirically documented.

Focusing on identity to advance ideas

Inquiry-based learning environments focus on advancing the ideas of their participants based on their genuine questions and interests. Scholarship, particularly the sociocultural perspectives we draw from, maintain that people's knowledge and identities are intertwined and inseparable (Herrenkohl & Mertl, 2010; Lave & Wenger, 1991). In practice, identities are often relegated to the background. For example, out of the twelve design principles that guide implementation of knowledge building communities (KBCs), not one of them focuses centrally on the participants' growth (Scardamalia, 2002). Empirical studies should be carried out to better understand the intricate relations between ideas and identities. The aim of this research is to examine how students' identities and knowledge are co-constituted in a specially designed learning environment, called a humanistic knowledge building community (HKBC: Hod & Ben-Zvi, 2018). HKBCs are designed to encourage their participants' freedom to express and explore both their identities as learners as well as the knowledge they choose to advance. By recognizing that identities and ideas are intertwined, it makes sense to design inquiry-based learning environments where participants can express, reflect on, and get feedback on their identities and knowledge, as well as the connections between them. Our analysis is therefore focused on showing the different ways that people's identities and their knowledge are co-constituted.

Background

Socioculturally-minded research has suggested that broad views of learning are necessary to conceptualize the advancement of knowledge (Herrenkohl & Mertl, 2010). Sociocultural approaches view the mind as inherently situated (Lave & Wenger, 1991) and therefore co-mediated across personal, interpersonal, and community planes (Rogoff, 1995). From a personal stand-point, learning involves transforming one's participation—and therefore identity—in a community discourse (Rogoff, 1995), oftentimes from peripheral to more central (Lave & Wenger, 1991). One's transforming identity is guided interpersonally, such as through apprenticeship learning (Eberle, 2018). Transforming into a central participant in a discourse cannot be achieved without advancing the ideas that are valued by the community. Ideas, knowledge, or what is informational (Hand & Gresalfi, 2015) are therefore intertwined with the identities of its participants.

Research already shows that broad views of learning can account for the co-mediational relationship between ways-of-knowing and ways-of-being (Hand & Gresalfi, 2015; Herrenkohl & Mertl, 2010). Our research builds on this proposition in two ways. First, we contend that the connection between ways-of-knowing and ways-of-being can be intentionally supported through design. Second, we differentiate between ways-of-knowing and ways-of-being with knowledge and identities. That is, ways-of knowing refer to people's epistemic commitments and the ways they build knowledge. Ways-of-being deals with non-epistemic domains, such as how people are viewed in social interaction. Although ways-of-knowing and ways-of-being focus on different things, they are both linked by practices or ways-of-doing *something*. When any practice is repeated enough to become stable (and is thus likely to be reified in discourse), it can be considered as an identifying feature of a person, or their identity (Heyd-Metzuyanim & Sfard, 2012).

In our research, we are interested in the actual knowledge that a person advances in relation to their ways-of-knowing and ways-of-being. Is it possible that the actual knowledge that people produce is closely related to their identities? If so, how? For instance, Wortham (2004) identified a bi-directional analogy of social identifications and epistemic concepts that people use while participating in classes. He noticed that students used cognitive categories to identify each other socially and these identifications help them understand concepts in person-related disciplines. Additionally, they also use epistemic concepts to identify others' socially. As Wortham (2004) notes, "it turns out that the content represented by a participant example and the interactional patterns enacted through that example can sometimes run parallel" (p. 177). Taking this forward, it raises the question of what would happen when students are given the opportunity to freely explore their ideas and their own identities in parallel within the community? These are questions from a broad view of learning that do not, to our knowledge, have any empirical accounts in the learning sciences.

Based on the rationale that knowledge and identities are inseparable, Hod & Ben-Zvi (2018) conceptualized the humanistic knowledge building community (HKBCs) as a designed learning environment that brings together idea-based and identity discourses. Idea-centered discourse is based on the theory and practice of KBCs (Scardamalia, 2002), while identity discourse is based on person-centered theories of personal growth through process oriented groups that focus on the here-and-now (Yalom & Leczsz, 2005). Both of these approaches are principle-based, fundamentally putting their trust and respect into the participants so they can take ownership and have agency over the processes they engage in while addressing the emergent goals of the community. The design of HKBCs gives students freedom-of-ideas and freedom-of-identities through designed activities, with a focus on jointly advancing both of these as part of the community goals. This research set out to study the different ways that students' knowledge and identities are co-mediated when they are given freedom-of-ideas and freedom-of identities. Specifically, we asked: (a) in what ways are students' initial expressions about their ideas and their identities related? and (b) how do students' ideas and their identities change as they are shaped through their ongoing participation in the community and by its members?

Methodology

Our data corpus was drawn from a full 14-week semester (2018-2019) from a graduate course that was designed as an HKBC and which included an entire group of 18 students, an instructor (moderator), and a teacher's assistant (co-moderator). CATELT was structured as a blended course, where weekly 210 minute face-to-face meetings alternated with ongoing activities for the remainder of the week in a wiki environment. Activities were generally designed to promote knowledge advancement by letting people explore their interests in relation to the community (freedom-of-ideas) or focus on people's experiences, interpersonal relationships, and identities in the here-and-now (freedom-of-identities) in both the face-to-face and online environments. Throughout the semester, we collected audio and video recordings of every face-to-face meeting, collected online artifacts created on the wiki by the students; and conducted open interviews at opportune times, either during breaks, or on the phone, when something interesting occurred as related to the research questions. Specifically for this analysis, we focused on two students (one presented here) within the course who worked as a pair on the final project, examining: (a) group reflection sessions; (b) personal reflective diaries; (c) wiki entries; (d) final papers; and (e) interviews.

To examine the initial identities and ideas of the students, we focused our efforts on the beginning stages of the course, where students typically reveal their prior knowledge and practices in ways that have yet to be tainted by the ongoing developments in the community. The sharing of interests and experiences was purposefully facilitated in activities designed by the moderators during the first few weeks of the course, as well. Once students' initial identities and ideas were collected, we examined the intricate and situational ways that these students both advanced their knowledge and interests and the way the community shaped these through their feedback or modelling processes. Ultimately, we created a narrative account of the findings (Erstad & Sefton-Green, 2013). To ensure that the analysis process was reliable, we engaged in extensive interpretive meetings together with another researcher in the course (who was focused on a different set of questions), and with a research group (to whom we presented the evidence and later engaged in discussion around it).

Findings

In this section, we report on Ziv (pseudonyms). *Due to page restrictions here and the lengthy nature of narrative accounts, we can only provide quick descriptions of his expressions instead of detailed, first-hand accounts.*

Ziv, aged 40, was a modern orthodox man who was a high school physics teacher. Ziv's identity was expressed as a person who was a 'knower' with 'absolute answers', analytical instead of personable, and controlling of collaborative learning processes. For example, in reflecting on group work, he explained that by working with a group the product was "mediocre", where if he was the leader he could bring it to excellence (Wk 4).

Given the conditions of freedom-of-identity that were supported in the course, Ziv's practices within the community ran parallel to those in his everyday life and to the ideas that he initially showed interest in the HKBC. Specifically, Ziv focused on the ideas of expertise and the Zone of Proximal Development (ZPD) through the lens of the role that teachers play in supporting learners. Ziv's interest reflected his identity in advancing himself as an expert teacher and "knower". For example, he wrote that that learning about expertise "was very meaningful for me because… it helps me very much as a teacher understand the learning processes that I see in the classroom and how [I can] facilitate this." In his knowledge building efforts around this idea during Wk 2, he focused on the highest levels of expertise and how he could get there. He chose to explore the topic of "adaptive expertise", reflecting about himself and providing a specific list of ways he could become an expert. Ziv's interest in the ZPD was similarly meant to advance his own teaching practices, again positioning him as the knower who needs to provide others with answers. He explained that his choice of ZPD as the main topic of his final course project was about how to turn a novice to an expert in what he referred to as an asymmetrical relationship between the two.

As the community got to know Ziv and recognized his practices, they were able to provide him with a wide range of customized feedback that promoted his identity development. The feedback he received covered many of the salient facets of his identity and practices, which especially came through in a dramatic community discussion around Ziv during Wk 8. There, many members of the community sensitively shared their thoughts about Ziv to him in the here-and-now, providing him with a new level of self-understanding that allowed him to make intentional changes to his identity and practices, for example:

> *Mod:* You want to get full control. We [in this course] are talking about something else. Most of us read and do not understand everything, especially something so complicated. I understand something partially and that is okay. How does it feel compared to the beginning [of the course]? There were tables and charts [that you created] for those who worked with you...

> *Nurit:* During one of the first reflections when we talked about changing, you told someone not to change. And maybe this is what you want for yourself? Maybe you need to release 'Ziv the physics teacher'.

The comments touched on a tender area for Ziv, giving him many new ideas about himself to reflect on. In the immediacy of the discussion he responded impersonally, but still in a way that suggested that he understood that his practices and identity could transform:

> *Ziv:* We learned in a very absolutist [educational] system. Maybe change is needed.

Throughout the remainder of the semester, Ziv exhibited a number of personal changes along these lines, suggesting that he appropriated the feedback. For example, during a collaborative assignment (Wk 10), students were asked to advance their collective knowledge. Ziv posted a note that expressed his uncertainty, "I still do not understand how to work with it but this is an opportunity to learn", and showed a high degree of openness about the process of work by writing, "I suggest that we work here [in a particular page] to build knowledge… what do you think?". These changes were also echoed in Ziv's final course reflection, where he noted that "I could have only guessed rationally before the 'hug', but once I experienced it, I can say that I understood it differently from the way I understood it in the beginning."

The changes to Ziv's identity were reflected in his changing focus of inquiry. Ziv's understanding of novices and experts as well as the ZPD shifted from (a) how the concepts can help him as a teacher, to (b) concepts that had diverse processes and social orientations. For example, Ziv participated in a small group discussion about the concept of ZPDs during Wk 8, where he emphasized that "The process [of novice and expert relationships] is reciprocal. The teacher also learns from what they [the students] bring…"

Whereas at the start of the semester Ziv focused on the ZPD from an asymmetric position where he was the expert, Ziv later took great interest in symmetrical social relationships, or how peers can help one another advance. This was reflected strongly in his final course paper, where he wrote:

> *Ziv:* Vygotsky did not give us explicit didactics in this concept and did not interpret his explicit intention of the mediator's identity... it is impossible to understand otherwise that any meaningful development of the learner will be based on a pedagogy of social learning, and not merely individual.

Discussion and conclusions

The research questions in this study sought to elucidate (1) the relatedness of students' initial expressions about their ideas and their identities, and (2) how these ideas and identities change as they are shaped through their ongoing participation in the community. In relation to the first question, Ziv's inquiry interests when given the freedom to be himself was deeply connected to his identities and practices in his everyday life. The narrative account of Ziv shows that his initial identity as 'the knower' was tied to his interest in being an expert (teacher) and the teacher's role as mediator in the ZPD.

Our analysis of Ziv's narrative showed that the actual ideas and the perspective taken on them were closely related to important aspects of his identity. This was expressed both in the interpersonal relationships that he formed within the community as well as from experiences that he told about in his life outside of the community. A close look at his knowledge thus provided a window into his identity, showing how inseparable these two concepts really are. The consequential feedback that Ziv was given about his interpersonal relationships in the here-and-now of the community was highly potent, as the ahistorical focus touched on deeper themes that ran across his everyday life. Thus, the feedback helped him think deeply about his identity and this ultimately shaped the way he viewed the ideas he was advancing.

Clearly this could have gone in the reverse direction also in that his advancing ideas could have shaped his identity. However, it is more likely to work in the opposite direction because identities are much broader than knowledge, dealing with the totality of a person, including their interests, beliefs, culture, history, goals, etc. Ideas, in contrast, are more transient and can be changed more easily. This is why, for example, knowledge can be built relatively quickly and ideas can be changed through argumentation. Changing conceptions are obviously very important and a central purpose of education. The point we are trying to make is that by addressing people's identities, we can touch on much more deeply rooted aspects of people's knowledge and this can ultimately help foster deep and sustainable knowledge and perspectives on it.

More specific to the learning sciences, the answers to our research questions are consistent with holistic notions of learning following sociocultural traditions (Herrenkohl & Mertl, 2010). They emphasize the importance of ever-deepening interpersonal relationships, as these provide opportunities for students to see aspects of people's identities that are often hidden behind masks they put on in their cultural roles as students who are not truly "free" to be themselves. Getting to know a person facilitates a deeper understanding of their ideas, particularly in settings like ours where the process of learning and knowledge are intricately tied together. Exploring issues of identity also facilitates self-understanding, and as we saw with Ziv, allowing a person to make more intentional decisions both in relation to how to engage in the knowledge building process as well as what topics to pursue. Obviously, it would be of high interest to see how these issues play out in other HKBC contexts, like math or science with kids, and we hope that future research will take up these questions.

Abstract: This study investigates youth civic participation around the 2020 US presidential election. Drawing on theory from civic participation, quantitative literacy, mathematics, and science education, this study describes *quantitative civic literacies*--how youth use quantitative reasoning as they "read" the social-political world and "inscribe" their own participation. We analyze a large collection of youth video production on youth-identified civic issues, specifically focusing on engagement around the "dual pandemic" of structural racism and COVID-19. Employing qualitative methods, we identified two emergent trends that shed light on intersections of quantification and youth civic production: 1) the paired usage of quantification and a human story, and 2) critiques of overgeneralization and totalizing quantification. This engagement reflects sophistication and awareness about the role of quantification and risks of over-reliance on quantification without deep human context. We offer implications for educators across disciplines, speaking to a core purpose of public education--critical and informed participation in democratic communities.

Introduction

The relationship between quantitative literacy, democracy, and schooling has been posed as an imperative for equitable futures in education (Ball, Goffney & Bass, 2005), and as a key civil rights issue for this millennium (Moses & Cobb, 2001). In an increasingly technologically advanced society awash in data, concerns about the abilities of the public to participate in the world as informed citizens have led to shifting definitions and priorities for literacy itself. Quantitative literacy has been posited as "the new literacy" (Steen, 1997), fundamental for participation in a modern-day democracy (Quantitative Literacy Design Team, 2001). Recently, data literacy has been added to this call (Boaler & Levitt, 2019). Yet few math or science classrooms, spaces ripe for quantitative reasoning as applied to civic life, explicitly engage students in civic topics. In the small set of literature documenting math and science classrooms that do so, findings suggest that young people are engaged, motivated, and ready to connect their disciplinary content learning to their social and political lives (e.g. Calabrese Barton & Tan, 2010; Gutstein, 2006; Levine, Keifert, Marin & Enyedy, 2020).

Beyond the math or science classroom, youth engage in civic participation and production in myriad ways, using multiple modalities (digital, visual, etc.) to critique, construct, and imagine their worlds (Kahne, Middaugh, and Allen, 2015). In the months surrounding the most polarizing election experienced by the United States (US) in modern times, over 1000 youth from across the nation produced and posted digital media addressing an issue of importance to them through the educational web-based platform, *Let's Talk About Election 2020*. In addition to the election itself, the Black Lives Matter movement and the COVID-19 global pandemic, coined the "dual pandemic" for the intersecting impacts of systemic structural racism with the virus-induced global medical crisis, provided a backdrop for students' recordings.

It is at this unique time that we seek to understand how youth are bringing together forms of quantitative literacy with civic production to reimagine their turbulent worlds. Contributing to the fields of civic participation, quantitative literacy, mathematics, and science education, the study takes youth media production in *Let's Talk About Election 2020* as the landscape for beginning to map the terrain of quantitative civic literacies - how youth use quantitative forms of reasoning as they "read" the social-political world and "inscribe" their own participation through civic engagement (Freire & Macedo, 2005). Specifically, this ongoing study asks: 1) How does quantitative literacy intersect with and contribute to different forms of youth civic composing? 2) When youth write about urgent topics such as Black Lives Matter and COVID-19, what forms does quantitative literacy take across these distinct civic terrains?

Youth, civics education, and civic literacy

Traditional conceptions of civics and civic education in the US are built around "characteristics of citizenship" (Flanagan & Levine, 2010) that promote a vision of civics in which students develop an understanding of the functioning of the US government. We make use of a more expansive conception of civics that includes a focus on “participatory politics” (Cohen, Kahne, Bowyer, Middaugh, & Rogowski, 2012), positioning schools as places that can support “participatory readiness” (Allen, 2016) for engagement not only in political communities, but also in “intimate and communitarian relationships” (p.27). In addition to informed consumption and production of civic-related information, this conception of civics includes the learning of empathetic listening for solidarity and the development of tools for imagining and creating more just and inclusive communities (Dewey, 1923). It furthermore advances a global perspective rather than one that is centered narrowly around the US.

Literacy has long been understood as fundamental to a participatory democracy, including participation in both governmental politics and the development of a more just and inclusive society (Dewey, 1923). In approaching the *Let's Talk About Election 2020* student videos, we use the construct of civic literacies to indicate the multiple modalities and spaces in which youth critique and create social and political worlds (Kahne, Middaugh, and Allen, 2015). With this study we begin to illuminate when and how different forms of civic composing reflect crucial intersections between civic and quantitative literacies.

Quantitative literacy

Building from the joint constructs of civic literacies and civic composing, we put forth a conception of civic literacies that includes quantitative literacies - argued as essential to equitable futures in education. In defining quantitative literacy, we draw from the Organisation for Economic Cooperation and Development (OECD) definition of quantitative literacy as the use of reasoning around: (1) quantity, (2) relationships and change, and (3) uncertainty to address “real life” problems (de Lange, 2006).

Quantitative reasoning is often associated with mathematics, and currently a central tenet of US-based K-12 standards for mathematics processes (NCTM, 1989; 2000) and practice (Common Core Standards Initiative, 2011); likewise, it is integral to several science and engineering practices outlined by the Next Generation Science Standards (NGSS; Achieve, 2013), such as using mathematical and computational thinking. Yet, quantitative reasoning embedded in meaningful social and political contexts is rarely accounted for in state-based measures that drive curriculum and instructional decisions. Orrill (2001) explains that quantitative literacy, distinct from school-based mathematics curriculum, “does not so much lead upward in an ascending pursuit of abstraction as it moves outward toward an ever richer engagement with life's diverse contexts and situations” (Orrill, 2001, xvii).

Methods

To answer the research questions, we enacted a qualitative analysis of transcripts from video and audio made by youth surrounding the 2020 US Presidential Election. *Let's Talk About Election 2020* offered an online, digital space for youth to share perspectives nationally via audio and video, hosted through public radio station KQED. Students chose a topic of meaning to them and produced an audio or video segment of approximately two minutes in length to post on the publicly available platform along with up to five “tags” describing the issues discussed. Some of these segments were chosen for public radio or TV broadcast then broadcast publicly through the national public radio or public broadcasting networks KQED and PBS.

Filtering from the set of nearly 1000 student made media segments, using student-posted “tags,” as well as media titles, we identified and examined the 51 media segments that addressed Black Lives Matter (BLM) and the 47 media segments addressing the COVID-19 pandemic. We downloaded these videos and audio segments as well as their student-produced transcripts. Initial analysis reported in this paper was limited to transcripts uploaded and coded in AtlasTI, a qualitative data analysis software.

Coding of transcripts employed a combination of a priori and emergent codes. In the first phase of analysis we applied an a priori framework, drawing on the three forms of quantitative literacy outlined by de Lange (2006), with modified operationalized definitions.

- **Quantity and number** - having to do with size, numerical patterns, measurement, representation of number, the meaning of operations, magnitude, computation, and estimation
- **Relationship and change** - having to do with growth, cycles, fluctuations, functional relations, equations, inequalities, equivalence, divisibility, making use of varied representations including symbolic, algebraic, graphic, tabular, and geometric.
- **Uncertainty** - having to do with data and chance, statistics, probability, and inference, collecting data, data analysis, data display and visualization

Through emergent coding, distinctions were identified between quantification that used numbers or statistics and non-numerically specific forms of quantification, forming sub-categories for each of the above three quantitative forms of reasoning.

Through a process of coding, memoing, and constant comparison among researchers (e.g. Strauss & Corbin, 1994) we identified two trends that sit at the intersection of quantitative literacies and civic composing: 1) the pairing of quantification with a human story and 2) critique of quantitative superlatives. Preliminary findings elaborate on these two trends.

Preliminary findings

Across both sets of transcripts, students used all three forms of quantitative reasoning, drawing less frequently on uncertainty than on the other two. Students often used numbers to communicate about historical or current events, but more commonly used non-numeric quantitative qualifiers such as "many," "more," "growing," "unequal," or "high risk" to describe magnitude, relationships, change, and uncertainty in probabilities.

Shared across both sets of transcripts, two trends emerged that shed light on intersections of quantification and youth civic production: 1) the paired usage of quantification and a human story and 2) critiques of overgeneralization and totalizing quantification. These two trends are highlighted in Figure 1.

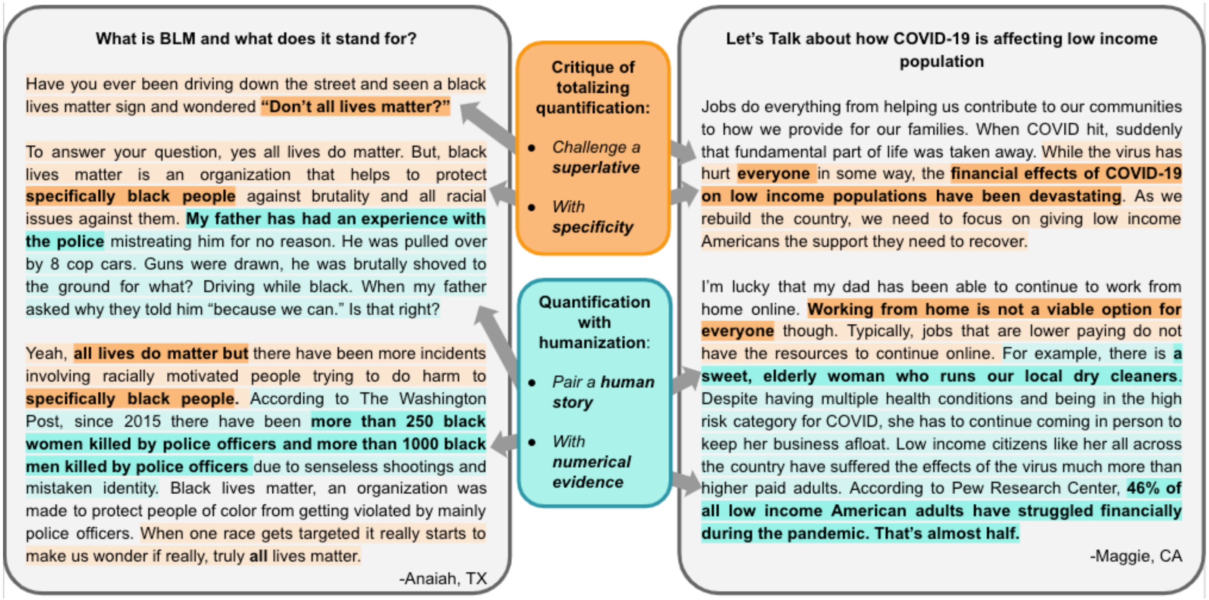

Figure 1. Coding from a Black Lives Matter and COVID-19 media transcript.

Quantification with humanization

Transcripts often evidenced a rhetorical move in which the author paired quantitative data with a human story to frame an argument. Using varied forms of reasoning with number, Anaiah from Texas tells the story of her father being pulled over by eight police cars and in doing so gives a face to the widespread anti-Black police violence that has led to fear, anger, and the deaths of "more than 250 black women" and "more than 1000 black men" in the US since 2015. Mixing together reasoning with number, relationships and change, and uncertainty, Maggie from California shares her concern about "a sweet, elderly woman who runs our local dry cleaners" who is "in the high risk category for COVID" but has had to continue working as an example of the ways that the coronavirus pandemic has disproportionately impacted lower income Americans, citing that "46% of low income American adults have struggled financially during the pandemic." With this rhetorical move, Anaiah, Maggie and others used the specificity of a personal story to humanize cold statistics that can abstract data from its lived significance. In subtle contrast to forms of civic composing that prioritize informing and treat quantitative data as the stamp of legitimacy, this rhetorical move appears to be one of solidarity in which quantitative data is treated as reliant on the legitimacy of the particulars of human experience.

Critique of totalizing quantification

While youth authors widely used non-numerically specific references to quantification, there were also many instances of critique of the usage of totalizing quantitative terms (superlatives) such as "all," "everybody" or "nobody." Youth media makers critiqued or rejected quantifications that were used to overgeneralize, arguing instead for the care and attention of specificity. In her video, Anaiah carefully confronts the question of "'Don't all lives matter?'," a common rebuttal to the claim that Black lives matter. As described above, she unpacks the specificity of violence against Black people including her own father, and the role of BLM as an organization and movement to challenge anti-Black violence. She highlights this challenge to the use of "all" in her closing line, "When one race gets targeted it starts to make us wonder, if really, truly, all lives matter." Maggie, like Anaiah, challenges the universality of experience; even when a pandemic is global, she argues, it does not affect everyone in the same way. For low income populations in particular, she writes, the effects "have been devastating."

Implications and next steps

These two ways of engaging with quantification in civic composing reflect a level of sophistication and awareness about the role of quantification in the world and the risks of over-reliance on quantification without deep human context and specificity. In the landscape of civic reasoning and argumentation, quantitative evidence is often understood to signal authority; instead youth media production on Black Lives Matter and the coronavirus pandemic suggests personalization and human experience as taking the legitimizing position.

Implications suggest that classroom-based instruction can build from youth awareness of the complexity of quantification. Youth quantitative civic literacies revealed in the two trends resonate with the call for deep contextualization of number and quantification in math and science classrooms (Calabrese Barton & Tan, 2010; Gutstein, 2006). Analysis identified the emergent findings described here from transcripts of audio from youth media. We will further pursue how youth communicate nuanced ideas about measuring and quantifying the stakes and impact of risks to human life within the dual pandemics of COVID-19 and Black Lives Matter.

Encountering Uncertainty and Learning to "Try and Try and Try": The Development of Teachers' Perseverance within Science

Shannon G. Davidson, Lama Z. Jaber, Sherry A. Southerland
shannongdavidson@gmail.com, ljaber@fsu.edu, ssoutherland@fsu.edu
Florida State University

Abstract: Current efforts in science education emphasize the need for students to experience science in ways that mirror professional scientists' practices and dispositions. As uncertainty is inherent in science, one important disciplinary disposition is then learning how to wrestle with uncertainty and develop a stance of perseverance at the encounter of uncertainty in scientific work. We argue that in order to support students in developing a stance of uncertainty in science, teachers themselves should be familiar and comfortable with scientific uncertainty. To this end, this study examines how four teachers encounter uncertainty and persevere in their work over the course of a six-week science research experience. Drawing from interviews and field observations, we identify key resources that facilitated teachers' development of perseverance and consider implications for instructional practice.

Keywords: Uncertainty, Frustration, Perseverance, Research Experience for Teachers, Science

Major issues addressed

Uncertainty is an inherent part of scientific endeavors. As scientists engage in constructing new knowledge, they can only do so by wrestling with uncertainty (Pickering, 1995). From this lens, uncertainty can be understood as the aspects of "scientists' work that [are] non-obvious and contingent, which must be figured out by the scientists and negotiated in response to feedback from peers and the material world" (Manz, 2018, p. 288). Indeed, scientists grapple with many kinds of uncertainty (Latour, 1987; Pickering, 1995). For example, scientists may experience conceptual uncertainty as they develop and flesh out novel explanations or engage in argumentation and critique of ideas. They may experience instrumental uncertainty when encountering procedural ambiguity or setbacks in using material tools. They may experience analytical uncertainty as they work to interpret data or when encountering ambiguous measurements. While not exhaustive, these examples illustrate that scientific uncertainty is inextricably bound to the disciplinary work of scientists. It is then important to consider how one learns to experience scientific uncertainty as motivating rather than stymying, and in turn, persevere through it. Said differently, navigating uncertainty includes not only working to reconsider methods and conceptual understandings (Manz & Suarez, 2018), but also learning to attend to and regulate the emotions that emerge within such work (Davidson, Jaber, & Southerland, 2020; Jaber & Hammer, 2016a).

Taken together, these perspectives on uncertainty inform current science education reform efforts (NRC, 2012) which emphasize the need for students to experience science in ways that allow them to think, behave, act, and feel as scientists (Ford, 2008). This entails providing students with opportunities to encounter uncertainty (Manz & Suarez, 2018) and develop the perseverance necessary to work through that uncertainty (Davidson et al., 2020). We argue that if teachers are to provide students opportunities to grapple with scientific uncertainty, it is essential that they also develop comfort with navigating uncertainty. Yet, few teachers have had first-hand experiences with uncertainty in scientific work. One context that may afford such experiences is that of Research Experiences for Teachers (RET) programs. RET programs are professional development experiences housed within national laboratories and universities, wherein K-12 teachers are immersed in extensive scientific research through shoulder-to-shoulder work with scientists (SRI International, 2007). RET programs may be fertile contexts for teachers to learn to persevere through uncertainty, thus this study asks the following questions:

1. In what ways do teachers describe and reflect on their experiences of scientific uncertainty in the context of a scientific research experience?
2. What are the resources that teachers refer to as productive to their development of perseverance in science as they reflect on these experiences?

Significance of the work

While professional scientists have sustained opportunities to develop perseverance through encounters with uncertainty over the long-term of their careers, K-12 teachers—and students—likely require carefully designed opportunities to develop such perseverance. By investigating teacher learning in the context of a carefully designed RET program, this study promises to a) contribute new insights with respect to the resources that learners recruit to navigate emotions and develop perseverance when encountering uncertainty; and b) consider the ways in which particular resources may be useful starting points for supporting K-12 students' experiences with uncertainty in the classroom. Additionally, given that uncertainty—scientific or otherwise—is fundamental to the human experience more broadly (Anderson et al., 2019), the insights garnered from this study have far-reaching implications for theorizing about learning and for designing for productive encounters with uncertainty.

Methodological approach

This study takes a naturalistic approach (Rossman & Rallis, 2012) to examine teachers' encounters with scientific uncertainty and development of perseverance during a summer research experience at a national laboratory in the southeastern United States. Through field observations and interviews, this study aims to capture teachers' experiences with uncertainty and the resources involved in developing their perseverance in light of uncertainty.

Research context

The study focuses on participants in a six-week paid residential summer RET program situated at The Lab—an interdisciplinary science facility with over 600 scientific faculty and staff from applied physics, materials science, and engineering fields. The Lab is made up of smaller lab groups comprised of research scientists, technicians, postdocs, graduate students, and occasionally undergraduate students. The RET is designed to provide K-12 teachers with opportunities to participate in cutting edge research with the hope that these experiences will influence their classroom instruction (Davidson & Hughes, 2018). Teachers' genuine participation in scientific research is a core tenet of the RET program at the Lab. For this, teachers are paired, and each pair is assigned to a mentor scientist with whom they work closely for the duration of the program. As part of their active and ongoing participation in the research work, the teachers are given explicit roles and responsibilities (i.e. preparing samples for experimental trials, running experiments and collecting data, assisting with lab reports).

Study participants

This study is part of a larger project focused on elementary teachers' disciplinary engagement in science. As such, purposeful criterion sampling was applied to select four elementary teachers (from a cohort of ten K-12 teachers) as the focal participants for this study: Ava, Carrie, Lynette, and Miranda. The four participants taught in K-5 classrooms, had varying levels of teaching experience, and expressed an interest in science teaching and learning.

Data sources and analysis

Data sources include five semi-structured and multiple informal interviews, field memos, and audio-recordings for over 30 hours of naturalistic laboratory observations for each participant. The interview transcripts serve as the primary data source with other data serving as secondary sources for triangulation. The semi-structured interviews, conducted over the duration of the RET, focused on the content of the research work; the teachers' relationships with their mentor scientist, cohort partner, and others at the Lab; their understandings about the discipline of science; and their feelings and experiences in doing research. In addition, multiple informal interviews occurred throughout the program as 'check ins' with participants about their experiences.

Each interview set was batched by participant and read in chronological order, starting with the earliest interview. Taking a constructivist grounded theory approach (Charmaz, 2008), the data sets were examined for moments in which participants discussed encounters with uncertainty. For the first research question, we attended to the type of uncertainty prevalent in these moments, drawing from definitions of uncertainty from Buck et al. (2014) and Manz (2018). We also paid attention to the context within which uncertainty emerged and the emotions that participants brought up in relation to each moment. To answer the second research question, we examined the interview transcripts again for whether and how participants reflected on their perseverance in light of uncertainty. When participants referenced perseverance, the transcripts were examined for specific resources that may have supported the development of such stance. We then identified themes that depict the resources that participants drew upon to develop perseverance and to embrace uncertainty as part and parcel of science.

Findings, conclusions, and implications

The study findings suggest that engaging with research at the Lab afforded participating teachers with firsthand opportunities to grapple with various kinds of scientific uncertainty. Each teacher described strong emotional responses—typically feelings of frustration and anxiety—associated with such encounters. In spite of these negative valence emotions, all teachers developed a stance of perseverance that was linked to specific resources.

Research question 1: Teachers' encounters with uncertainty

The teachers described twenty-three separate encounters with scientific uncertainty over the course of their six-week research experience. Across all four cases, the participants primarily described grappling with conceptual uncertainty—difficulty explaining particular scientific ideas—and instrumental uncertainty—difficulties arising from working with physical equipment (Buck et al., 2014). As an example, Ava reflected on a particularly vexing experience with instrumental uncertainty as she and her lab mates, Carrie—a peer teacher—and Kevin—a graduate student lab member—repeatedly tried to create a single composite image file from many smaller files using unfamiliar computer software and a handout that their mentor scientist, Dr. Ji, had given them:

> We kept looking at [the handout] Dr. Ji had given us and every time—every single time—it just wouldn't work. One [of us] would say, 'did you try this?'—Yes—'what about this button?'—Yes—everything. I think we tried everything! And we couldn't make it work. We couldn't. Carrie would try and then Kevin would say, 'No, no! I'll try' and then he'd stop and I'd try—it was crazy. We had to take a break even, we had to walk away. (Interview 3)

When reflecting on their encounters with uncertainty, almost all participants expressed an emotional stance of frustration, anxiety, and feelings of discomfort. However, all four teachers described ways in which their frustrations were mitigated, normalized, and transformed to a stance of perseverance. As Ava noted after describing the composite image problem: "It was really frustrating! I could not believe how hard we had to think to do something so simple—well, it's not simple! We didn't know how to do it! But you have to practice and try and try and try, you have to see it as a challenge" (Interview 3). While she acknowledged her frustration, she also noted the importance of framing this encounter with uncertainty as "a challenge" along with noting the necessity of continuing to "try and try and try", a stance reflective of her emergent perseverance.

Research question 2: Key resources in teachers' development of perseverance

There were two prevalent resources that all four participants referenced as being most productive for developing perseverance in light of scientific uncertainty: Support from mentor scientists and peers.

Mentor scientists: Normalizers of uncertainty

Across all participants, the resource most often referred to was mentor scientists who were described as a source of help and comfort when encountering uncertainty. In each encounter, mentor scientists made explicit moves to normalize uncertainty. Ava noted across multiple interviews how "patient" her mentor scientist was. Reflecting on an instance when a scheduled power outage caused an experimental trial run to go awry, she noted:

> I felt really frustrated and upset when the furnace must have shut down during our [experimental] trial run, --like what do we do? How can we fix this and run it again? But [my mentor scientist] was like 'No no no, don't worry. This happens. This is part of it--part of, you know, science.' He didn't make me feel bad, but [rather] it's just part of science. (Interview 4)

Efforts to normalize scientific uncertainty on the part of the mentor scientists tended to emphasize forward movement—(e.g. acknowledging the difficulty but stressing that one must keep going)—a sentiment that aligns with perseverance. The mentor scientist's moves to support Ava by normalizing uncertainty and offering consolation (see above) exemplify similar moves made by other mentor scientists who, particularly in light of instrumental uncertainty, were quick to reassure the teachers that such encounters were "part of science".

Cohort peers and junior lab members: Commiseration in frustration

Another key resource in supporting all four teachers' development of perseverance was that of their RET cohort peers, as well as members of their lab groups who were *not* their mentor scientist. These more junior lab members typically included undergraduate and graduate students whose research was related to the work of their mentor scientist. We choose to present RET cohort peers and junior lab members as a single key resource in teachers' development of perseverance because of the comparable role they played in affirming and commiserating with our teachers' experiences of frustration and anxiety in light of uncertainty. Each of the four teachers in this study were able to articulate moments in which conversations with others served to reassure them that they were not the only ones experiencing frustration and anxiety, and that such feelings were warranted and reasonable responses for the moment. Having their feelings heard, acknowledged, and identified with by those in similar positions as themselves often served to motivate the teachers to persevere through the encounter with uncertainty, even if these commiserations did not necessarily eliminate teachers' frustration.

Conclusions and implications

Throughout the RET program, the four teachers encountered scientific uncertainty multiple times, experienced frustration in response to uncertainty, and developed a stance of perseverance over the course of the program. Developing perseverance in light of uncertainty, we have shown, was facilitated by interactions with mentor scientists and peers. This finding underscores the essential nature of social interactions as a core feature of productive scientific research experiences (Southerland et al., 2016). The roles of these two key actors (mentor scientists and peers) served different functions. Mentor scientists made moves that attempted to quell teachers' anxieties around uncertainty, as well as to normalize uncertainty as a natural part of scientific pursuits. Interactions with peers afforded teachers opportunities to identify and empathize with one another around their encounters with uncertainty and their related feelings of frustration. In tandem with this, having firsthand experiences with science and having commiserate peers allowed these teachers to begin to normalize and embrace the emotions inherent in scientific work (Davidson et al., 2020).

Teachers of science who have wrestled with scientific uncertainty and have been supported to develop a stance of perseverance may be well positioned to support their own students to productively navigate encounters with uncertainty—and corresponding feelings of frustration—in the science classroom. As the field continues to examine ways to incorporate scientific uncertainty into students' learning experiences (Manz & Suarez, 2018), we argue that both teachers and their students should have opportunity to feel as scientists do in relation to uncertainty and to be afforded opportunities to navigate their emotions in order to persevere in science.

Agency and Expressivity in Programming Play

Selena Steinberg, Vanderbilt University, selenasteinberg@gmail.com
Melissa Gresalfi, Vanderbilt University, melissa.gresalfi@vanderbilt.edu

Abstract: Computer programming has been conceptualized as an expressive medium, but little is known about how to best support students in exercising agency and engagement in coding tasks. This paper draws on data from a five-day summer camp for middle school students that integrated computer science and movement. We focus on an activity in which students created choreography and modeled it in the programming environment NetLogo. The task was designed with the goal of creating opportunities for students to exercise agency and expressivity while coding. We analyze the extent to which *incompatibilities*, or moments of mismatch between what is possible in the dance versus NetLogo environments, shaped students' agency and exploration. Our findings suggest that designing with incompatibilities positioned students with agency over their models and supported their own expressive goals.

Introduction and framing

Computer science has far-reaching connections to multiple fields that vary widely from science, to geography, mathematics, art, and beyond. Each application reveals new potential for the ideas, development, and applications of computer science. There are many questions about how these different contexts frame and support students' engagement in computer science. In this study we focus on computer programming as an expressive medium and explore how features of a designed space that intentionally constrains students' choices influence the ways they ultimately exercise agency in their own programming work.

The connection between computer science in general, and coding in particular, with art and artistic expression is not new, although it continues to be a less well-developed venue for computer science connections than other disciplines such as engineering or science (Arts Education Partnership, 2004; Maeda, 2001). There are some who argue that coding is a new medium that can be used to allow for maximum expression—an urgently needed new tool to ensure that artists communicate across all outlets (Edmonds, 2019). Others argue that the integration of technologies and computational thinking into the arts supports the development of an entirely new field, Media Arts (Peppler, 2010). Regardless of its name, coding languages can be seen as both expressive and representational systems, as they allow for the development of images, stories, and experiences that represent and make connections with the messages and experiences an artist conveys.

Coding can also be seen as an act of empowerment, in that telling stories and rewriting tools offers a new way to read and write the world (Freire, 1970/1996; Ryoo et al., 2020). Thus, coding has the potential to position students with agency as they determine for themselves how to tell their own stories. But how can programming environments best be designed to support exercising agency? In other fields it has been well-established that the mere fact that a discipline *can be* explored with agency and authority doesn't mean that it *will be.* Instead, careful attention must be paid to the nature of the tasks that organize activity, the norms of the classroom in which students are situated, and the ways students are positioned relative to each other if students are legitimately to have an opportunity to exercise their own agency (Gresalfi & Hand, 2019).

While the field of computer science education is still in the beginnings of exploring curriculum design for k-12 contexts, there are many places to look for insight into how to proceed, and indeed these ideas have already started to be taken up in the field. Specifically, the fields of math education and science education have a long history of emphasizing the potential of play and exploration as crucial ways of engaging with the core practices of problem posing, exploring structure, and problem solving, and such practices are likely central to supporting students to engage in programming with agency and authority (Wager & Parks, 2014). Bringing play into mathematics also provides opportunities for children to come to see themselves as "math people" (Parks, 2015). Reshaping mathematics norms and practices serves to position students differently with respect to the discipline, broadening not only the experiences that students might have, but also, how those experiences lead them to reach different conclusions about their abilities and preferences.

This analysis explores how particular features of task design invite students to exercise agency over and creative expression in their own coding and projects. We define agency as an act of volition, which can include making choices, defending decisions, or deciding when the model is correct. Expressivity is defined as an exploration of representational possibilities with a focus on artistic or aesthetic goals. We focus on a modeling activity that asks students to represent their own dance and translate it into NetLogo code, which requires that students determine for themselves whether their translation is sufficient. In what follows, we offer an overview of the study and the particular tasks that are the focus of this analysis, and then present findings that demonstrate how those tasks supported students to exercise agency and creative expression in their coding.

Study setting

We analyze data from a free five-day summer camp for middle schoolers held in a southeastern city in the United States in 2019. This camp integrated movement and computer science in order to leverage full body movements as an expressive form of computational learning. It utilized the programming environment NetLogo (Wilensky, 1999), a multi-agent environment in which students use text-based programming language to manipulate movable agents (turtles). There were two classrooms, one with 11 students and one with 13. Each classroom was staffed by two teachers and one teaching assistant. Additionally, two researchers moved through both rooms, providing coding help when requested.

This analysis focuses on an activity that occurred on the second day of the camp called the Telephone Game, co-designed by researchers, professional dancers, and the teachers that led the camp. In our variation, student quartets created a choreography "message" using a large square sheet of mylar, coded their choreography in NetLogo, and then switched models with another group and interpreted them as choreography. This paper considers the second phase of the activity: using NetLogo to model dance choreography.

Students were provided with two possible setup buttons, both consisting of four turtles connected in a square shape with links. As students coded, they were expected to encounter moments where they had to make decisions about how to model their dance because of differences between what is possible in the system of mylar/dance and what is possible in the system of NetLogo. For example, in the dance world, it is easy for people to let go of the mylar and move to another location, but in NetLogo, moving a turtle (often viewed by students as the people in their model) also causes the links (viewed as the mylar in the model) to move. We call these moments of mismatch between what is possible an *incompatibility.* Students encountered an incompatibility when their model behaved in NetLogo in a way that would be impossible using mylar and physical movement.

The activity was intentionally designed to engage students in the task of translating between incompatible systems, with the goal of creating opportunities for students to exercise their own personal agency in resolving these incompatibilities. The environments of the physical dance world (four people moving with a mylar prop) and the world of NetLogo (a two-dimensional space containing turtles, patches, and links) have vastly different constraints, providing space for making representational choices in NetLogo and interpretive choices with the mylar. In this way, unlike the traditional telephone game, the task was designed to not allow for a single correct answer or a more or less "accurate" interpretation. Rather, the task invited students to explore the expressive potentials of both environments and positioned them with agency to explain their discoveries.

Methodology

We examine screencaptures of six students independently coding their dances in NetLogo. We included only the students that worked independently (i.e. without the constant presence of a peer or teacher, though students did talk to each other and ask for help) in order to be able to understand students' decision-making process without guidance and suggestions throughout from a teacher. These students represent all the consented participants with screencaptures that worked independently on the task. Three students (Chris, Jonah, and Zaair) were in both the same classroom and the same quartet. The students in the other classroom were in two different quartets (Harrison and Xavier were in the same quartet and Kyle was in another).

As stated, one of our goals for the activity was to invite students to exercise personal agency and foreground their own expressive goals as they made representational choices. We seek to understand what students do when they encounter mismatches between what is possible in each context. Our research questions are:

1. How does working with representational systems with incompatibilities position students with agency in evaluating their models?
2. How does encountering incompatibilities invite expressivity?

Analysis

There were several phases of analysis. First, we watched students' NetLogo screencaptures multiple times, using principles of grounded theory (Strauss & Corbin, 1994) to write analytic memos for each student. Throughout this process, incompatibilities emerged as a theme across videos, and we began focusing on students' decision-making process in moments where the model did not behave as they expected. In order to further explore these moments, in our second round of analysis, we turned to open coding using the video coding software V-Note. The videos were parsed by marking each incompatibility and whether students reacted to it. This coding helped to highlight important or interesting decision points in students' coding practice. In a larger paper (Steinberg & Gresalfi, 2021), we share the details of the breadth of this coding. In this paper, we look closely at two particular phenomena: whether and how students seemed to exercise agency, and how incompatibilities led to exploration.

Findings

Agency

There were two features of the activity that appeared to support student agency. First, the task of translating between intentionally incompatible representational systems meant that students could not create a model that was an exact replica of their choreography. As they encountered incompatibilities, they had to make decisions about whether and how to address them. This decision-making was inherently personal; some students were satisfied with representations that portrayed only the movement of the mylar while ignoring what the people did, while others wanted to accurately portray both. Students demonstrated agency in navigating these incompatibilities. Second, the activity was designed to allow students to model a dance that they created, which positioned students to determine for themselves when their representation was finished. For example, Jonah believed that he captured the dance with his model (Figure 1 Image A), but when he showed it to Chris, a peer in his quartet, Chris saw lots of things that needed to be changed. When Jonah told Chris that he was done, Chris responded by questioning why the person was running backwards and explained that "it should be going in the middle, and those two guys'll come in closer, and then they'll go back out." Jonah rejected Chris's advice, by saying "Ok, no I was gonna do something..." and edited his model so that two turtles moved in and out instead of just one (Figure 1 Image B). Jonah again showed Chris his model and asked Chris if it looked like they're trading places. Even though Chris responded "It's going so fast you can't see it," Jonah remained confident in his own interpretation, and said "See, they're switching spots for a second, then they're going back." Jonah made a final move to set the shape of his turtles to people, and then a teacher checked in. Jonah told the teacher, "I think I may have completely done one of them" (Figure 1 Image C). While Jonah and Chris disagreed on how to represent the dance, Jonah followed his own instincts and was ultimately satisfied with his representation.

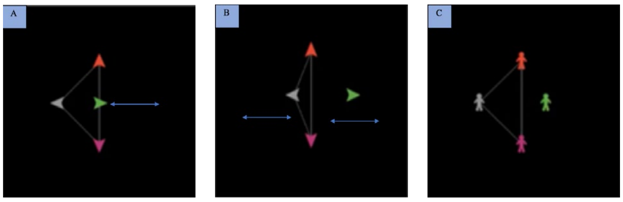

Figure 1: Jonah's NetLogo choreography as he negotiated his own and a peer's representational interpretations. Blue arrows demonstrate movement of turtles.

Incompatibilities created opportunities for choice, which led to model diversity and afforded agency to students. Because of the personal nature of the dance, there was no one correct answer, and even students with the same choreography ended up with different final models. To show letting go, Zaair deleted the links completely, Chris drew the mylar using the pen function, and Xavier used turtle size to show who was holding on. Students were positioned as the only ones that could decide when their model was "good enough".

Expressivity

While students were often frustrated by the presence of incompatibilities, there were some cases where students were inspired by the incompatibility and used it as an opportunity to extend the model artistically. For example, Kyle chose to represent the person/mylar system using a single turtle shaped square, and as he made his square mylar grow and rotate, it eventually became so big that the turtle wrapped (an incompatibility). Capitalizing on the appearance of this model, Kyle began adding more square turtles to the model, creating an aesthetically pleasing effect. Here, Kyle built on and extended the incompatibility, deviating from his choreography. The goal of his model changed from representing his choreography to creating a work of art of another form.

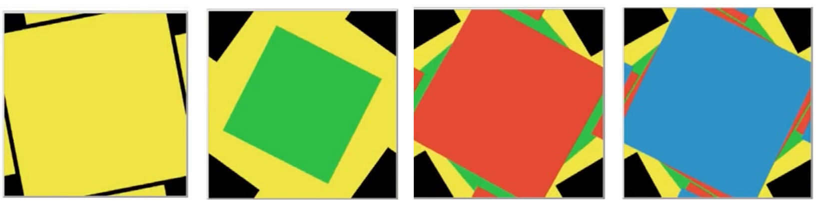

Figure 2: Kyle's artistic expansion of an incompatibility.

Other students also commented on the artistic quality of their models. As Harrison tried to figure out rotating, he expressed, "That's a cool animation but it's not what we need." When Jonah encountered the world wrapping, he said, "Hahah, I ripped it into pieces!" While not all movements explored made it into the choreography, exploring them helped to broaden what students understood as possible in the environment. Incompatibilities prompted exploration of the boundaries of a representational environment and invited artistic expression that was different from the straight modeling task. Students were able to exercise their own agency as they imaginatively explored the space of possible mappings between their NetLogo representation and their dance and moved from describing the dance towards expanding it.

Discussion and conclusion

In our analysis, we found that as students encountered incompatibilities, they exhibited personal agency over their coding as they made choices about which elements of the dance were important to foreground in their models to create a satisfying representation of their dance. Incompatibilities helped students to see the expressive possibilities available in NetLogo. Our findings reveal that bringing computer programming together with an embodied, creative experience like dance can support student agency and expressivity. Specifically, asking students to model a phenomenon that they created themselves and that had different properties than the programming environment was productive. Brady (2018) suggests that it might be desirable to pose problems where learners encounter limitations in order to prompt them to move beyond the target concepts to build more sophisticated understandings. Likewise, in encountering the limitations of NetLogo to create an exact replica of the dance, our students engaged in representational play and demonstrated agency in evaluating their models.

Interactions with Peers on the Path to Math Success

Nikki G. Lobczowski, Carnegie Mellon University, nikkilob@cmu.edu
Elise Morton, Georgia Institute of Technology, elliemorton@gatech.edu

Abstract: A key strategy to being successful in math is help-seeking. Much research has focused on how students seek help from teachers, but students also benefit from peer assistance. We analyzed conversations from eight focus groups related to students' paths to success in math. We found that students frequently brought up peer interactions as critical to their success. Three emergent themes were: support versus comparison, balance of effort within study groups, and friends versus peers. Our findings qualitatively extend current research by highlighting key ideas that impact peer interactions, such as increased reluctance to seek help in larger classes. Our findings have implications for classroom and group structures, including encouraging peer help-seeking and help-giving, as well as addressing belonging and sense of community.

Introduction and background

As students learn, they may face challenges that require assistance to overcome. However, in the face of adversity, students do not always seek help, which can inhibit their academic achievement. In school environments, students are shaped by their interactions with peers. With more detailed accounts of how peer interactions can aid or harm students' paths to math success, educators can orient their classrooms to set students up for math achievement, potentially through peer interactions and collaboration. While the current literature focuses on quantitative patterns, this study seeks to learn more about how students describe their lived experiences.

Seeking help when navigating obstacles to learning is a key self-regulated learning skill (Karabenik, 2011). Although students tend to focus on teachers for learning support, using peers as a resource has additional benefits. Access to multiple explanations (i.e., beyond that of the teacher or text) of mathematical concepts can help students experience new perspectives (Tripathi, 2008). Moreover, helping others and seeing peers model success can increase self-efficacy and ownership in learning (Walker et al., 2010). Help-seeking from peers can also increase socialization, an important developmental skill for younger students (Newman, 2000).

Despite the benefits, some students still avoid seeking help for many reasons. For some, the likelihood of seeking help is negatively related to the perception of subsequent psychological risks (Peeters et al., 2020). These can include embarrassment in admitting confusion or errors (Karabenik, 2011), fear of frustrating the teacher or slowing down the class (Peeters et al., 2020), indebtedness to the help-givers (Karabenik, 2011), and negative social comparison to other more-capable peers (Newman & Schwager, 1993). Additionally, if students lack confidence in their peers' (or even the teacher's) ability to understand their confusion and provide adequate help, they will likely not seek help (Newman, 2000; Peeters et al., 2020).

Students' help-seeking behaviors and peer interactions are also related to their academic achievement goals (Roussel et al., 2011; Shim & Finch, 2014). Compared to students focused on demonstrating competence in relation to the task itself or their own previous competence (mastery goals), students focused on demonstrating competence in relation to others (performance goals) are less likely to engage in productive help-seeking behaviors or see peers as instructional and emotional supports (Shim & Finch, 2014). Naturally, when students focus on their own learning and improvement, rather than in relation to others, they are less likely to fear social comparison (Roussel et al., 2011) or engage in competitive, maladaptive behaviors' (Newman & Schwager, 1993).

Most studies on peers as a resource are quantitative, focusing on identifying variables that impact help-seeking behavior and learning (e.g., Roussel et al., 2011). More research is needed to understand how students think about interactions during peer support and how these can help them overcome challenges while learning math. Therefore, in this qualitative study, our research question is: *How do students describe interactions with peers on their paths to math success?*

Methods

We conducted focus groups twice weekly for four weeks (n = 8) to learn more about students' experiences while learning math. We posed pre-scripted questions to the students in these structured sessions, which were held online virtually due to the COVID-19 pandemic. Our recruitment targeted identity-based affinity groups at nearby colleges, from whom we recruited current undergraduates, graduate students, or recent graduates. The participants (n = 25) were students from universities mainly in the northeastern United States and one student who attended a university in the southeastern United States. Results from an optional demographic survey show a diverse group of participants for both race (12% Asian, 20% Black, 16% Latinx, 4% White, 2% Multi-race, 1% Other, 36% Unspecified) and gender identity (20% Male, 40% Female, 4% Genderqueer, 36% Unspecified).

This study is part of a larger project aimed at understanding student experiences in overcoming challenges to achieve math success. In each focus group, we asked students to describe past challenges during math learning, the effects on their sense of belonging, overcoming these challenges, facing new challenges, and advice for others. Although participants were not explicitly asked about their peers, we found that peer interactions was an emergent theme, particularly when participants were asked about their experiences, resources, and belonging. The codes we used to describe these interactions were peer relationships, peers as a resource, and belonging among peers.

We developed a codebook to capture students' experiences and challenges based on their discussions in the focus groups. This codebook used deductive codes based on the current literature and inductive codes that emerged throughout our research process. We coded for students' experiences with support and resources, identity and belonging, and persistence. Each focus group transcript was double-coded, and researchers met to reconcile any differences. The overall interrater reliability was over 80% and 100% once reconciled. For each segment of the focus group transcripts with a peer-related code, we identified the student's description of their experience and added an analytic memo regarding the key idea that the student discussed. After completing this for every mention of peer interaction, we derived three common themes. Students described (1) themselves as supported by or in comparison to their peers, (2) the need for balance of effort within study groups, and (3) describing other students as "friends" vs. "peers." We then chose representative excerpts for each of these themes to illustrate how the students (using pseudonyms) articulated their experiences with peers.

Results

The students' descriptions of interactions with peers included asking for instructional help, seeking emotional support, and working in study groups. We found three emergent themes related to how students described their peers and peer interactions as they discussed their paths to success in math.

Support versus comparison

Many students noted the benefits of getting peer help, specifically the positives of studying in small groups. For example, Sunny (Black, genderqueer) noted that "developing a more group style of working helped a lot," adding how they initially worked alone in college and would go to office hours for help. In later years, however, they "learned how to work with [their] classmates and set up study sessions sometime in the evening. Then if [their group] couldn't get it on [their] own, then [the group] would go to TA office hours together." Lucia (Latina, female) expanded this idea by also recommending a friend group "that's supportive of you and understands how you're feeling and knows that everyone struggles with something and math may be the thing you're struggling with." Eliza (no demographic data) also discussed the importance of having "more knowledgeable peers" (Newman, 2000, p. 352) in the study group: "there was usually one person that understood everything the professor said the most, so [the group] would just make him or her the teacher in a sense, and it was a smaller class. It was like five people." Zora (Black, female) added that even when no one in the group understood the instructor, there was a sense of community in the confusion that helped prevent feelings of isolation.

Conversely, some students describe peers more as a unit by which to compare their understanding and performance. This could be seen in Mario's (Latino, male) description of his struggles in a college math course, stating, "[my peers] had an idea of what was going on and I didn't. Even when we got together in groups to study and whatnot, I was the one that was making the really dumb questions." He later admitted that he thought that he was so far behind that the professor and classmates would think less of him because he "wasn't at their level." In his case, the support given by his study group was overshadowed by the insecurities he felt when he compared himself to his classmates. Interestingly, Eliza also noted a similar comparison in extracurricular activities, discussing how they joined an engineering club in which they were "scared to ask questions to [other club members]." Eliza ultimately left the club due to overwhelming feelings of discomfort and questioning their self-worth. Eliza went on to describe finding an identity-based organization for Latinx students, noting that many of these members also questioned their daily worth. Through this organization, Eliza learned about imposter syndrome and found a sense of community: "These are my people. This is where I need to latch on and just trust that we'll all make it through together. It did challenge me, but then I also was able to find my niche." Eliza's example demonstrates the importance of a sense of belonging and community within a peer group.

Balance of effort within study groups

Several students discussed the importance of balance with regards to effort within peer study groups. Lucia stated that she would "spread [her] asks around" to avoid "burdening any one person" and that this strategy would increase everyone's willingness to help. Ryder (no demographic data) discussed the reciprocality of asking help from and giving help to peers: "I get very worried about being parasitic, but it felt a lot more mutual, so it was nicer in the long run." Eliza discussed group members taking turns going to office hours. When personally confused about the content, Eliza would always volunteer to go from the group. These students' statements imply an attentiveness to group functioning and highlight a key give-and-take mechanism for productive study groups.

Friends versus peers

As seen throughout the previous examples, there was a clear divide in how students referred to those from whom they sought help. Some referred to them warmly as "friends." Lucia stated, "I know a lot of my friends have been really understanding. I've definitely broke down crying about stupid math problems before to multiple of them, and they've all been really understanding, and they're just really reassuring." Others, as seen in the comparison examples above, referred to them as peers, implying a detachment or weak relationship with them. We had two graduate students discuss a possible explanation for these differences: class or cohort size. Eliza stated that issues with belonging in their undergraduate program were related to the "size of the group or the class." Eliza elaborated to describe how the uncomfortable feeling in one large class: "If you ask a question, it spooks you out a bit because you have 300 faces looking at you wherever you're at." Ryder expanded this idea by describing the differences between their master's and undergraduate programs. The master's program was "pretty small" with around 14 full-time students, which allowed students to "[get] to know each other really well." Ryder added, "It was easier to ask people I knew because with the high student-teacher ratio in undergrad, it just really meant that I still didn't know any of my classmates for whatever reason, whether I felt like I belonged or not." Ryder also explicitly stated, "grad school math definitely went a lot better because I did ask for help from somebody."

Discussion and conclusion

In this study, we qualitatively analyzed students' descriptions of interactions with their peers in their path to math success. To date, most research on this topic has been quantitative, focusing on factors influencing peer help-seeking such as the perception of psychological risks and negative social comparison. Our study confirms many of these findings but benefits from an in-depth qualitative analysis to further explain and expand the current literature. For example, we had descriptions of insecurities and low self-worth, resulting from social comparisons, that interfered with peer help-seeking. We also saw expressions of a spectrum of achievement goals from performance-oriented (e.g., Mario comparing his performance to his classmates') to mastery-oriented goals (e.g., Lucia working with peers to gain a better understanding of the content).

We also had findings that extend the literature. First, our findings related to belonging and community were connected to a new important consideration for peer help-seeking: class or cohort size. The graduate students in the study were able to provide a clear comparison between large undergraduate and smaller master's class sizes, demonstrating the difference in their ability to know and connect to their peers. Next, we found that students discussed the balance of effort in small peer groups and how knowledge and tasks can be distributed among group members. Interestingly, even when no one in the group understood the content or task, there was still a need for non-content support (e.g., validation). This extends the current literature on help-seeking by connecting to research on socioemotional regulation strategies (c.f., Lobczowski et al., in press). These findings highlight the importance of a sense of belonging among peers, as well as building a community, especially among small groups.

Implications, limitations, and future directions

Our study has implications for both research and practice. First, it highlights the importance of setting group norms related to balancing effort. Similarly, students should not only be encouraged to seek help when needed but also volunteer assistance when applicable. This will help create a culture of peer support in the classroom. Instructors of large classes also need to find ways for students to interact and get to know one another. For example, students could participate in partner discussions during class or collaborate on group projects. Each of these ideas can help increase a sense of belonging and community with the classroom and small peer groups.

Although we had a limited sample of participants (*n* = 25) in our focus groups, this allowed us to hear more from each participant and dive deeper into their experiences. In the future, our findings could be used to create a survey to reach a broader audience. Despite our efforts to recruit participants from a variety of universities, our pool represented a smaller group of institutions. However, the participants comprised a diverse group of majors and disciplines. Going forward, we will seek out participants from institutions varying in size, both large and small. During the focus groups, we did not explicitly ask participants about their peer interactions, yet it was mentioned in all but one focus group and emerged as an overall theme. In future research, we would like to ask participants directly about their experiences with their peers.

Developing Social Empathy through Human-Centered Design: The Iterative Journey of Designing an Instructional Booklet for Pre-Service Teachers

Carrie L. James, Saadeddine Shehab, Gail Rost
cljames2@illinois.edu, shehab2@illinois.edu, gailrost@illinois.edu
University of Illinois Urbana-Champaign

Abstract: A critical goal of teacher preparation programs is to support pre-service teachers (PSTs) in understanding their future students and communities. One way to do this is by assisting PSTs in developing social empathy. This paper describes the design and implementation journey of three prototypes of a social justice in education instructional booklet that aims to engage PSTs in developing their social empathy through human-centered design (HCD) processes that aim to help them understand people from varied backgrounds and their unmet needs. Our prototypes were informed by a conceptualization of social empathy that encourages PSTs to understand people who come from different social backgrounds and findings from research that define concrete techniques to empathize with the users. We discuss the design and implementation of the fourth prototype of this booklet and propose a study to evaluate the impact of the booklet on PST's development of social empathy.

Keywords: human-centered design, social empathy, culturally responsive, teacher education

Introduction

In culturally responsive teaching, teachers embrace students' diverse "cultural knowledge, prior experiences, frames of reference, and performance styles … to make learning encounters more relevant to and effective for them," (Gay, 2010, p. 29). While pre-service teachers (PSTs) may come in with a desire to support diverse students, effectively preparing them to do so starts by fostering their development of social empathy – empathy for those outside your own group identity (Segal, 2011). Social empathy, paired with a clear understanding of social justice and culturally responsive pedagogy, allows teachers to embrace their students' funds of knowledge (Gonzalez, et al., 1995). Nevertheless, our knowledge of pedagogical approaches that can engage PSTs in learning experiences where they practice and develop social empathy is limited.

One potential pedagogical approach is to engage PSTs in human-centered design (HCD), a problem-solving approach that identifies the unmet needs of a population to collaboratively and iteratively develop solutions (Brown, 2008). Research shows that when educators explicitly engage learners in HCD, they develop several mindsets including human-centeredness (Goldman & Kabayadondo, 2017). Social empathy, a component of this mindset, manifests when people "begin to move beyond egocentric views of the world and no longer design based on their own needs, desires, experiences or preferences" (Goldman et al., 2012 p. 17). HCD fosters the development of this mindset by having people actively engage in empathic techniques (Hess & Fila, 2016) such as being immersed in a person's world, interacting with them in interviews, and reflecting on their perspectives.

Considering the capability of HCD experiences to assist learners in developing social empathy, this paper addresses the question of how we might engage PSTs at an historically white institution (Dancy, 2018) in HCD experiences that assist them in developing their ability to empathically understand their students and communities. The paper describes the design and implementation of an instructional booklet that aimed to engage PSTs in empathic moves, as part of HCD, to complete a community placement assignment in an introductory social justice in education course at a land-grant institution in the Midwest. The booklet takes us one step further toward supporting PSTs in practicing social empathy and addresses the need in the field of teacher education to support PSTs in developing human-centered mindsets so they can better serve their future students and communities.

Conceptual framework

Research on empathy is grounded in the fields of social work and psychology. Segal et al. (2017) define empathy as a cognitive-affective construct. "Affective empathy describes the physiological aspects of vicariously feeling what another person is feeling, while cognitive empathy involves the mental processing of another's feelings, thoughts, or intentions" (p. 11). Segal et al. label this interpersonal empathy. It includes taking the perspective of others while maintaining self-other awareness and regulating one's own emotions. Interpersonal empathy is the basis for social empathy, which is the ability to understand people by perceiving or experiencing their life situations and as a result gain insight into structural inequalities and disparities" (Segal, 2011, p. 266-267). They described social empathy as having both a macro self-other awareness and macro perspective-taking ability that tasks us with understanding people different from ourselves "by putting ourselves in the situations of others with different characteristics of group identity, such as race, gender, sexual orientation, ability, age, and class background" (p. 27). Social empathy responds to the systemic barriers affecting people in marginalized groups.

In the context of HCD, designers use social empathy to truly understand those for whom they design. Hess and Fila (2016) highlighted this in examining how undergraduate engineering students engaged in empathic techniques as they engaged in HCD to design an accessible zipline experience for youth campers with disabilities. These undergraduates demonstrated 12 empathic techniques: direct observation, empathy by proxy, interaction, projection, empathic concern, synthesizing empathic knowledge, design for user-centered criteria, integration, refine user suggestions, check with user, and imagined use. These empathic techniques support the authors' conceptualization of empathy, which is similar to Segal et al. (2017). Their model explicitly addresses a self-other dimension. They described this dimension as being a dichotomy where people are "imagining how another feels or thinks" or "imagining how one would think and feel in another's situation" (p. 94). This emphasis on self-other awareness aligns with the characteristics present in both a human-centered mindset and HCD. Finally, the concept of social empathy, in the context of HCD, is not complete without the ethical perspective (Boylston, 2019; Segal, 2018) that urges designers to take on the role of creating socio-cultural solutions by being aware of their ethical obligations (Manzini, 2015; Reznick, 2019) and setting aside biases and assumptions. The ethical component challenges those using HCD to question who the best person(s) is to respond to the unmet needs faced by others.

PSTs are the future designers of learning experiences for students from diverse backgrounds. Therefore, it is important that PSTs develop social empathy during their teacher preparation programs so they can better understand, support, and include their future students and communities in their instructional designs, especially when the majority are white. For example, PSTs must examine the biases they bring to designing innovative learning experiences, particularly for those in marginalized populations. Without this step, their concern for social justice issues will be hindered by the simple fact they may be designing from biased perspectives. Engaging PSTs in HCD experiences, specifically the empathic techniques identified by Hess and Fila (2016), may assist them in developing social empathy. Nevertheless, we still lack research-informed instructional tools that can engage PSTs in learning about and implementing these techniques to recognize, develop, and practice social empathy.

Design solution

To support PSTs in developing social empathy, we co-designed an instructional booklet that guides PSTs in implementing the processes of the Understand, Synthesize, and Ideate spaces of the HCD taxonomy (Lawrence et al., 2021) with instructors and teaching assistants (TAs) of a social justice in education course. The activities in the booklet specifically engaged PSTs in exploring and observing an educational setting, empathizing with the stakeholders in the setting, reflecting on their biases, organizing collected information, identifying patterns, defining design opportunities, and suggesting potential solutions. These activities provided explicit experiences and instruction that align with five of the 12 empathic techniques identified by Hess and Fila (2016) (see Table 1). In their research, they determined that students participating in an immersive HCD experience were able to demonstrate these empathic techniques because they actively interacted with actual users as part of the service-learning opportunity. While their research focused on what they observed, we took their work further by designing specific activities that explicitly engage students in each of these techniques both in theoretical and practical ways. Our goal is to further develop PSTs social empathy by explicitly engaging them in these techniques as they navigate through HCD, so they better understand their stakeholders and determine their unmet needs.

Iterative design process

First iteration: Spring 2019 and Fall 2019

The introductory social justice in education course is a required course for future PSTs that focuses on identity and difference. This course has three central components: course lectures, teaching assistant-led discussion sessions, and a community placement experience where PSTs are required to visit and engage in an educational setting to apply the course content to explore, and understand the setting, and reflect on their experiences in the setting. Prior to Spring 2019 semester, the course did not explicitly include any elements of HCD.

In Fall 2018, a newly established design center at this university contacted the course professor to discuss potential collaboration as part of the center's initiative to integrate HCD in higher education courses. In our initial conversations with the course instructor, he noted that the three previously mentioned course components worked well independently, however, he noted it was hard for students to connect the learning outcomes from these components. The professor wanted to design an instructional tool that would help students make strong connections across course lectures, discussions, and their community placement experiences in their final reflection paper for the course. However, he insisted that he wanted this done with minimal change to the existing course curriculum and structure. After brainstorming a set of ideas, we decided to design an instructional booklet that would assist students in approaching the community placement experience using HCD. In our design of the booklet, we aimed to assist students in connecting the course content to how they implement HCD processes and document their learning outcomes during their community placement experiences. We also aimed to foster students' development of human centeredness. In this first iteration, IDEO's human-centered field guide (IDEO, 2015) informed our design of the instructional booklet. It was composed of five sections: Assumptions and Hypotheses, Observations, Interviews, Patterns, and Insights, and Design opportunities. Each section included prompts that guided the students in implementing the relevant HCD processes and documenting the outcomes.

Table 1: The five techniques from Hess and Fila (2016) reflected in the booklet.

Empathic Technique	**Definition**
Direct Observation	Observing stakeholders in the context where the problem/design challenge exists to understand the context, problem, and users.
Empathy by Proxy	Speaking with intermediaries who act on behalf of users or who are middlemen between the designer and user in order to define constraints.
Interaction	Interviewing and talking with potential users of your design to develop understanding of their needs.
Projection	Mentally putting oneself into the shoes of the users to encourage reflection and deeper understanding of the users.
Empathic Concern	Using learnings about potential users to help set design criteria that align with the users' well-being. This typically relates to safety concerns and design constraints.
Synthesize Empathic Knowledge	Often in concert with empathic concern, synthesizing all learnings to set design criteria - including defining constraints and design opportunities.

At the end of Spring 2019, we administered a post-course survey to assess students' knowledge of HCD processes and acquiring HCD skills (Shehab et al., 2021). The 23-item survey used a 5-point Likert Scale with 1 = strongly disagree and 5 = strongly agree. Forty students completed the survey; many were neutral toward almost all items. Instructor and TA interviews further explained this finding, stating the booklet added more structure to the community placement exercise, however, they mentioned that the booklet did not make the necessary explicit connections between the course content and the different HCD processes, including those on empathy.

In light of the collected data, we developed a second prototype of the booklet in Fall 2019 by making minor changes. We added an Introduction section where we explicitly stated the definition of HCD and the purpose of the booklet as a tool to apply HCD processes to design relevant and meaningful solutions to problems identified during the community placement experience. We also met with the instructor and the teaching assistants who suggested reducing the number of interviews that the students were required to conduct. The booklet was implemented again in the Fall 2019 semester. To gain a better insight of how the students were using the booklet, one researcher from the center observed one discussion section whenever the TA was engaging the students in the content of the booklet. Observations suggested the need to guide the TAs through assisting the students as they use the booklet. Seven students consented to share their completed booklets with the research team. Examining the content of the booklets suggested that the students are using the course content to complete some sections; however, we still needed to add sections that could help students think about and reflect on their participation in the HCD processes, which in turn, can promote their development of social empathy.

Second iteration: Fall 2020

Prior to Fall 2020, we designed a third prototype of the booklet based on the first iteration. We incorporated three central changes. The first focused on building in instructional activities that explicitly engaged students in the five empathic techniques that are described in Table 1. For example, we included an interview planning guide that asked students to think through who they needed to interview and what kinds of questions they needed to ask them. We also added reflective practices (Goldsmith, 2012), such as self-assessment rubrics, that allow students to reflect on how well they engaged in HCD processes throughout the booklet. These changes made HCD processes more transparent for the students, the TAs, and the instructor of the course. Finally, to support TAs, we built in guided notes in a teacher's edition of the booklet. These guidelines gave TAs explicit tips to help students engage and reflect on HCD processes more fully. For instance, in the student's edition, students were asked to answer the question "Who are you?". To support TAs in helping students to critically answer that question, we included guidelines that encourage TAs to "unpack" that question by describing positionality and perspective.

Discussion

Navigating the iterative process of designing this booklet required aligning the needs of the course with the possibilities of integrating the HCD processes. Each iteration built off feedback from instructors and students as well as researchers' observational data. Additionally, as the booklet evolved, research on HCD, particularly on empathy education, has influenced the types of activities that are included in the booklet, particularly in the third prototype. The first two iterations revealed that students have a somewhat clearer understanding of how to implement HCD processes after the course. However, we still have little insight into how effectively this booklet supports students in developing a human-centered mindset, specifically social empathy. Further research must be done to establish the booklet's effectiveness in developing social empathy in future PSTs. Therefore, we propose to conduct future research that seeks to explore the question: how does an HCD booklet impact students' generation of empathic solutions to educational problems and the development of social empathy? This study will conduct both pre- and post-surveys that seek to measure students' social empathy levels. Additionally, the research team will gather observational data of discussion sessions to document the interaction between TAs and students with the booklet. Finally, we will collect students' completed booklets and conduct content analysis to examine if students demonstrated evidence of effectively engaging in the empathy techniques promoted in the booklet and generating empathic solutions to educational problems. We will also conduct interviews with students to understand the impact of the booklet on their development of social empathy and their perceptions of its use in designing curriculum for their future students and communities. The proposed study has the potential to impact our understanding of using HCD pedagogy in teacher preparatory programs. Particularly, evidence that the booklet does in fact help PSTs develop social empathy as part of a human-centered mindset as they engage in Hess and Fila's (2016) empathic techniques will support the argument that empathy is teachable, and explicitly engaging learners with these empathic techniques in instructional activities fosters that learning.

Ideologies, Teacher Discourse, and Language Learning in the Elementary Science Classroom

Bethany Daniel, Vanderbilt University, bethany.r.daniel@vanderbilt.edu

Abstract: The monolingual ideologies that are systemically reproduced in the United States educational system impede equitable learning for all students, and particularly for multilingual learners. Drawing on Philip's (2011) ideologies in pieces framework, this study seeks to understand what elementary science teachers' discourse reveals about their ideologies surrounding language and science learning. Using qualitative video analysis, I analyzed discourse from three elementary science teachers. I found that teachers' discourse about language learning both reproduced and contested systemic monolingual ideologies, while their discourse about science learning was primarily asset-based. Implications include design suggestions for professional development as well as further research to gain a deeper understanding of how teachers might transfer asset-based ideologies across learning contexts.

Introduction and theoretical framework

Monolingualism is positioned as normative in U.S. education, despite an increasingly ethnically and linguistically diverse student population. Reforms such as the Next Generation Science Standards (NGSS) push for rigorous content for all learners, but the language demands required by these standards often remain invisible for teachers working with multilingual learners (Buxton & Caswell, 2020). Ideologies, defined by Louie (2020) as "a resource—not necessarily good, and not necessarily bad—that teachers use to make sense of their work" (p. 3), impact the instructional practices teachers use to support multilingual learners (Lemmi et al., 2019). It is important to note that monolingual ideologies are systemically reproduced and lead to inequitable learning opportunities (Valdez et al., 2016). For example, the ideology that language proficiency is a necessary prerequisite to engaging with science concepts (Lee et al., 2007), might lead teachers to lower expectations and provide less ambitious science learning opportunities for multilingual learners.

Teachers may inherit monolingual perspectives reproduced by the educational system and (un)consciously express them through their instructional practices. However, recent research has shown how professional development (PD) can help teachers interrogate and disrupt these ideologies and shift their practice in ways that are more inclusive to multilingual learners (Lemmi et al., 2019; Menken & Sánchez, 2019; Pacheco et al., 2019). Because discourse is one way in which ideologies are made manifest (Pacheco et al., 2019), this study considers elementary science teachers' talk about their multilingual learners in the context of a PD and what their discourse reveals about common language ideologies in relation to science learning.

In considering teachers' ideologies, I draw on Philip's (2011) framework of "ideologies in pieces." Philip views ideologies as a tool born through a *sensemaking* process that comes from one's own or others' lived experiences or from social assumptions. These *commonsense* elements of ideologies are widely accepted in a community with little need to justify them and are often difficult for individuals who hold them to articulate or explain. Similarly, because monolingual ideologies are reproduced by the educational system, many teachers accept them without question based on the cultural assumptions about language learning. Over time, ideologies within a community may go through a *rearticulation of meanings* as the accepted commonsensical meanings are questioned and new meanings are negotiated (Philip, 2011). Philip also notes that because ideologies are context-specific, conflicting ideologies can coexist for an individual. Thus, teachers may hold problematic monolingual ideologies alongside predominately asset-based science learning ideologies.

Methods

As Pacheco et al., (2019) note, "discourse not only provides a lens into teacher thinking but gives shape to ideologies that inform practice" (p. 198). Thus, by analyzing teachers' talk about their practice, I seek to identify the inherited ideologies that emerge through the teachers' *sensemaking* process about their multilingual learners, as well as if and how the *commonsense* elements of those ideologies undergo any *rearticulation* of meanings (Philip, 2011). Finally, I contrast these language ideologies with teachers' discourse about their science practice.

Nine teachers from a large urban school district in the southeast U.S. participated in this study, which was part of a multi-year PD project designed to focus on the use of representations in inquiry-based science. This data came from the first year of the project, which included an initial five days of summer PD where teachers were positioned as learners and as instructional designers. One hour of this initial PD focused on strategies for supporting English learners (EL). Participants then met quarterly during the school year for video clubs. At each club, teachers analyzed and reflected on student work and on video of their classroom science instruction (Sherin & Han, 2004). Reflecting on multilingual students and their science learning was a discussion prompt at each video club but was not always discussed. The last club of the year focused explicitly on ELs.

Data sources for this study included the four video club sessions from Year 1 of the project. All video recordings of the sessions were transcribed and reviewed for teachers' turns of talk focused explicitly on ELs, which became the units of analysis. These units were then studied using a qualitative content analysis of video data (Powell et al., 2003) to identify language ideologies as manifest through teachers' discourse. A representative five-minute clip is highlighted in this paper. The clip came from the final video club of the year, in which three of the nine participating teachers were discussing a science lesson taught by Soren, a kindergarten teacher. The three teachers included Soren; Kourtney, a third-grade teacher; and Toni, a fourth-grade teacher. In Soren's lesson, students were using a representation to identify objects in the schoolyard as living or non-living. The facilitator, also a research team member, asked Soren if she felt that the words or the pictures on the representation were more helpful to the students. Over the course of the next five minutes, all three teachers shared narratives about their ELs. These individual narratives are presented below, as well as an analysis of some of the ideologies that emerged from this discussion about the language learning process in the context of science learning.

Findings

The teachers' discourse about their ELs sometimes reified and sometimes challenged monolingual ideologies about language, but their discourse was consistently more asset-based when discussing science. These coexisting ideologies were reflected in the contrast between participants' narratives and sensemaking around their ELs and the language learning process and their analysis of their science practice. Soren's narrative began in response to the facilitator's question about words or pictures being more helpful to her kindergarten students. Soren noted that one of her ELs began the school year easily able to understand "pictorial representations," and because both of her ELs are "very bright", they quickly learned vocabulary and caught up to participate along with the class. Toni responded to Soren's narrative by highlighting the importance of students having content knowledge about science in their home language before learning science in English. Soren agreed and attributed her students' success to the fact that most of the ELs at her school have parents who are involved with research at universities in the area, so the students come in with background content knowledge. Kourtney provided an additional example as she shared a narrative of two students in her class, one of whom was not literate in Spanish and struggled learning English, while the other student was literate in Spanish and quickly achieved some English proficiency. Toni built on this example with her narrative of a student from last year who started the year and "knew absolutely no English, yet he exited out of EL at the end of the year." Toni attributed this success to several factors, including intelligence, language skills in his home language, prior academic success in his home country, parental support, and parental knowledge of English. Figure 1 highlights the different ideologies that the teachers used as tools to make sense of the narratives and of the language learning process.

Language Ideology 1: There is an important relationship between students' prior knowledge & their emerging English abilities.	
Soren	"He **came in understanding pictorial representations** nicely but **adding the vocabulary** to it was a lot of what we did at the beginning of school for him especially…[he's] coming from a background where **[he has] all of that [background knowledge]**."
Kourtney	"I have one [student] who can [read and write in Spanish]…And **she is speaking in English**. She came in the first day of school and **she wrote me three paragraphs about herself in Spanish. She is writing paragraphs in English now**"
Toni	"When they have **the content knowledge in their own language first** it makes a big difference. … So like, that's huge, I mean to be able to go from no English to exiting EL in one year. It's crazy, but it's because **he was just making a connection to what he already knew**."
Language Ideology 2: Successful language learning is a result of students' innate abilities & attributes.	
Soren	"He caught on pretty fast, **and he's a very, very intelligent child**. …Somehow I'm blessed with these two babies who came in not speaking much English or understanding much English **but they're so bright** that they have not made me work very hard."
Kourtney	"And so the one who was literate…is writing paragraphs in English now…in less than a school year, because she had those skills…but it does illustrate, I mean **part of it is motivation**."
Toni	"I had a kid last year who came in first day of school knew absolutely no English, yet he exited out of EL at the end of the year, but **he was really bright in Spanish**."
Science Ideology: Students bring a wide range of resources with them that can be drawn on to engage in rigorous scientific sensemaking.	
Soren	"I was trying to ask them questions **based on themselves**, often, **or other living things that they understood**."
Kourtney	"So they might **make a connection** between one of the representations…Oh, now that I see this other one, **I can relate it to something else that I already know**."
Toni	[Questions to help students make connections] "What does that **mean**? Where is this **happening**? How could **you describe that to someone that wouldn't know** what the Ring of Fire is?"

Figure 1. Representative ideologies about language learning and science

Figure 1 highlights three representative examples of the teachers' ideologies. The first demonstrates a language ideology with elements that contest systemic framings of monolingualism as normative, while the second appears to reify traditional monolingual ideologies. The third presents a contrasting asset-based science ideology. The first ideology teachers articulated was that there is an important relationship between students' abilities in their first language and their emerging English abilities. Teachers' talk showed a fairly sophisticated understanding of the support that first language literacies can provide when learning an additional language. They recognized that existing skills in other languages serve as vital resources for students as they learn English (Menken & Sánchez, 2019). This framing begins to contest monolingual discourses that position students with emerging English proficiency as not having the language resources necessary to engage in scientific sensemaking (Lee et al., 2007). At the same time, teachers' articulation of this ideology was limited to identifying how multilingualism supports language learning; the articulation did not extend to consider how first language resources might be leveraged in science learning.

The second ideology, that students who successfully learn English do so as a result of innate abilities, revealed ways that participants viewed language learning as something exceptional that they as teachers played little role in supporting. The participants' discourse connected their multilingual learners' English abilities to personal attributes such as being "bright" or "intelligent" or "motivated." Such perceptions echo the ways that monolingualism is positioned systemically as normative. In the U.S., access to studying languages in other than English in school is limited most often to academically successful, primarily white monolingual English speakers (Reagan & Osborn, 2002). On the other hand, minoritized learners' skills in languages other than English are seen as deficit (Flores & Rosa, 2015). Thus, participants' discourse implied that "successful" English language learning was positioned as an exceptionality attributed to intelligence or other external factors.

The teachers' discourse surrounding language learning both reinforced larger, societal ideologies and began to challenge some of these ideologies. In contrast, the teachers' discourse about their science practices throughout the video club conversation highlighted ideologies that primarily challenged traditional conceptualizations of science. Rather than viewing science as an abstract set of facts to be learned with students entering as blank slates, all of the teachers recognized that students brought a wide range of experiences with them that could become important resources for engaging in rigorous scientific sensemaking. For example, Soren drew on students' lived experiences and prior knowledge as valuable resources in understanding scientific concepts (Lee et al., 2007). Similarly, Kourtney described using multiple representations to support students in making connections across contexts, allowing them to build their understanding of scientific concepts over the course of instruction instead of expecting them to memorize decontextualized facts (Lee et al., 2019). Finally, in reflecting on a lesson about volcanoes, Toni identified an opportunity where she could have pressed on one student's background knowledge about the Ring of Fire to push her student's thinking further. Toni saw using questions as a discourse strategy that engaged students in scientific sensemaking while attending to audience and register (Lee et al., 2019). All three of the participants' discourse about science practices pushed back on dominant ideologies of science to describe science through inquiry-based, student-centered ways.

Discussion

The teachers' discussion about their English learners and science practice reflected multiple aspects of Philip's (2011) ideology in pieces framework. Rather than drawing on their own personal experiences as learners, they used their *commonsense* lived experiences as teachers to "make sense of, define, figure out and render intelligible the way [language learning] works" (Hall, 1996, as cited in Philip, 2011, p. 300). The narratives of students served as a *sensemaking* tool as the teachers articulated their understanding of the language learning process to and with each other. It is noteworthy that the teachers did not challenge each other's narratives in any way, nor did the facilitator challenge the teachers' narratives. In other words, the ideologies expressed about language learning did not undergo any *rearticulation of meaning* in this community at this time. Instead, participants built on one another's ideas to co-construct the ideologies presented in Figure 1, suggesting that for this group of teachers, the ideologies represented "socially communicated assumptions or experiences of others taken for granted" (Philip, 2011, p. 302). The participants made sense of language learning for ELs in ways that often reified but occasionally challenged dominant ideologies. By contrast, their sensemaking about science was primarily asset-based, likely a result of shared understanding about science learning developed through PD participation. Because language ideologies often go unexamined (Lemmi et al., 2019), as was the case in our PD design, we wonder how teachers might shift toward asset-based framings when invited to examine these assumptions.

Philip (2011) also notes that "people are not compelled to reconcile their sensemaking across contexts, and they may make sense in seemingly contradictory ways without being troubled by it" (p. 300). Evidence of the fact that these teachers' ideologies were in pieces could be seen in the contrast between the teachers' discourse about language learning and their discussion of science learning. The discourse surrounding language learning drew heavily on others' experiences, discussing students and "their" work connecting, thinking, and learning in a somewhat detached way. Although teachers started to contest some monolingual norms in their ideologies, their discourse fell short of discussing how they as teachers could leverage all students' language resources for scientific sensemaking (Pacheco et al., 2019). By contrast, participants' discourse surrounding science learning was grounded in their own experience in the classroom. Teachers discussed things "I" could do, providing examples of their own instructional decision making to center and honor the knowledge students brought with them into science lessons. The co-existence of somewhat deficit-based language discourse alongside more asset-based science discourse highlighted the contradictory ideologies Philip identifies. Because ideologies are context-specific (Philip, 2011), this group of teachers may be ready to engage in *rearticulation of meanings* if facilitators on the research team made salient the dominant monolingual ideologies and invited them to challenge some of the commonsensical meanings of their language learning narratives to create new meanings that pull teachers' asset-based views of science learning across the two contexts.

Implications and potential impact

An immediate implication of this analysis is in the design of future iterations of this PD project. In reviewing findings from the first year, the research team recognized a greater need to attend to the relationship between science and language. Key goals moving forward include (1) drawing attention to deficit discourse surrounding multilingual learners that is embedded in educational systems and taken up by participants and facilitators, and (2) providing perspectives and asset-based language that contest monolingual norms. It is our hope that the asset-based ideologies teachers express with regard to science learning can be extended to other learning contexts. Furthermore, this work may contribute to a deeper understanding of how ideologies about language learning are taken up, expressed, and contested, leading to more equitable learning opportunities for all multilingual learners.

CS1 Student Assessments of Themselves Relative to Others: The Role of Self-Critical Bias and Gender

Jamie Gorson, Northwestern University, jgorson@u.northwestern.edu
Eleanor O'Rourke, Northwestern University, eorourke@northwestern.edu

Abstract: University introductory computer science courses (CS1) present many challenges. Students enter CS1 with varying backgrounds and many are evaluating their potential for success in the major. Students often negatively self-assess in response to natural programming moments, such as getting a syntax error, but we have a limited understanding of the mechanisms that drive these self-assessments. In this paper, we study the differences in student assessments of themselves and their assessments of others in response to particular programming moments. We analyze survey data from 214 CS1 students, finding that many have a *self-critical bias*, evaluating themselves more harshly than others. We also found that women have a stronger self-critical bias, and that students tend to be more self-critical when the other is female. These insights can help us reduce the impact of negative self-assessments on student experiences.

Introduction

The rapid growth of computing has prompted learning scientists to study approaches for broadening participation and improving learning experiences in computer science (CS). In this paper, we study student experiences in introductory CS courses at the university level, often referred to as CS1. CS1 courses are the entry point to the CS major, but often suffer from learning challenges as they serve students with a wide range of prior experience in computing. Specifically, students who are new to programming often struggle when grouped in classes with more experienced peers (Ott et al., 2018), and feel pressure to quickly evaluate their ability to succeed in CS due to the need to choose a major (Lewis et al., 2011). These challenges are often amplified for women and students of color, who are underrepresented in CS and drop out of the major at higher rates (Cohoon, 2006).

Recent research has shown that CS1 students frequently assess their own ability (Kinnunen & Simon, 2012). While evaluating progress is important for self-regulation (Butler & Winne, 1995), these studies show that students negatively assess themselves in response to programming moments that are natural parts of professional practice (LaToza et al., 2006), which are therefore not helpful indicators of ability. For example, many students believe that they are performing poorly when they stop to think or plan, get a compiler error, or forget syntax (Gorson & O'Rourke, 2019). Students who negatively self-assess more strongly in response to these moments have lower self-efficacy on average, an important factor that predicts persistence in CS (Lewis et al., 2011).

To address these issues in student experience and persistence, we need a better understanding of the mechanisms that drive student self-assessments in CS1. While there are likely many factors that contribute to these self-assessments, in this paper we specifically explore how students assess themselves in comparison to how they assess others. Studies show that people tend to have a self-enhancement bias when evaluating themselves compared to others, rating themselves more favorably (Alicke, 1986; Kwan et al., 2004). At the same time, women tend to under-evaluate their performance in science (Ehrlinger & Dunning, 2003), and have a weaker self-enhancement bias (Kurman, 2004). Given the challenging learning context that CS1 presents for many students, we were interested in understanding how factors such as gender might shape negative self-assessments.

Student self-assessments in CS1

Studies show that CS1 students frequently assess their own ability (Lewis et al., 2011; Kinnunen & Simon, 2012). Through an interview study, Lewis et al. (2011) discovered that self-assessments play an important role in CS1 students' decisions to major in CS. Kinnunen & Simon (2012) found that students often evaluate programming experiences negatively even when they are successful, especially when the experience does not match their expectations. More recently, we built on this research to identify criteria that students use to assess programming ability, such as writing code that runs on the first try (Gorson & O'Rourke, 2019). Through a survey study with 214 students, we found that many negatively self-assess in response to these natural programming moments, and that those who report stronger negative self-assessments have lower self-efficacy (Gorson & O'Rourke, 2020).

This body of research highlights the prevalence of negative self-assessments in CS1. However, we still have a limited understanding of the factors that drive these assessments. Our previous study revealed correlations between students' beliefs about professional practice and self-assessments for a few of the moments (Gorson & O'Rourke, 2020), however these effects do not fully explain students' negative views of their own ability. In this paper, we explore another factor that could explain negative self-assessments, namely differences in how students assess themselves in comparison to others and the role of gender in these self-assessments.

Differences in assessments of the self and assessments of others

Social psychologists have studied differences in the ways individuals assess themselves and others extensively (Kwan et al., 2004). In many domains, people tend to hold overly positive views of their own abilities, an effect that is referred to as *self-enhancement bias* (Alicke, 1986; Kwan et al., 2004). For example, Alicke (1985) asked college students to rate the degree to which a set of trait adjectives characterize themselves and the average college student, finding that students rated themselves significantly higher than others for desirable traits.

Self-enhancement bias does not necessarily arise as strongly for students who experience stereotype threat. Ehrlinger and Dunning (2003) gave college students a pop quiz on scientific reasoning and found that female students rated themselves more negatively on scientific skills and estimated performance on the quiz than male students, even though there were no gender differences in actual performance. While we are not aware of any studies of self-enhancement in the CS domain, we might expect to see similar effects as in other STEM domains. Women are notably underrepresented in CS (Cohoon, 2006) and prevalent stereotypes depict computer scientists as male, technologically oriented, and socially awkward (Master et al., 2016). Given this context and the frequent negative self-assessments of CS1 students, we wondered whether there are any differences in student assessments of themselves and others, and how gender might shape these assessments.

Research questions

The goal of this paper is to study differences in how students assess themselves and others in response to particular moments that arise during the programming process. Towards this end, we conducted a secondary analysis of the data from our previous survey (Gorson & O'Rourke, 2020) to answer two research questions: (1) are there differences in students' assessments of themselves and their assessments of others? (2) Are the differences in these assessments impacted by the gender of the student or the other? We aim to understand whether any self-assessment biases might help explain the prevalence of the negative self-assessments while programming in CS1.

Methods

This paper reports on a secondary analysis of data we collected in February 2019 (Gorson & O'Rourke, 2020). We recruited participants from three universities of different types and with different levels of selectivity in the midwestern United States. All participants were enrolled in an introductory course at their university and 36% of participants identified as female. See our previous paper for a complete description of the data collection methods. In this section, we review the subset of the survey that is most relevant for understanding the present analysis.

The survey was designed to uncover student self-assessments in response to specific moments that might arise during the programming process. We designed a set of thirteen vignettes that each describe a fictional character encountering one of the programming moments that may prompt negative self-assessments. An example vignette is: "*Diego starts working on a programming problem. He writes a few lines of code. He realizes that he is confused about what to do next. He pauses and plans his next steps. Diego wishes that he did not have to stop writing code to plan*." After each vignette, students were asked how much they agree that the character or themselves are performing poorly when they encounter that moment, on a six-point forced-choice Likert scale. For this vignette, the statements were: "*Since Diego had to stop and think, he didn't do well on the problem*" and "*When I have to stop programming to plan, I feel like it means that I'm not doing well on the problem*." The gender of the vignette character was communicated through the name and the pronouns used in the vignette. To control for any biases in participant responses, we randomized the names of the characters across vignettes.

Findings

Students evaluate themselves more critically than they evaluate others

To answer our first research question, we measured whether there were differences in students' assessments of themselves and their assessments of the vignette characters. We first converted the responses to the two forced-choice Likert-scale questions following each vignette to a numerical scale ranging from -3 (strongly disagree) to 3 (strongly agree). By agreeing to a statement that follows a vignette, participants demonstrate a belief that they (or the characters) are performing poorly during that moment. Therefore, to calculate self-critical bias we subtracted their response to the question about themselves from their response to the question about the character for each vignette question. For example, a participant may *slightly agree* (1) that the character is performing poorly in a particular moment, and *slightly disagree* (-1) that they are preforming poorly. We would calculate 1 minus -1 resulting in a self-enhancement bias of 2 for that vignette. A positive value indicates a self-enhancement bias in participants' responses. We grouped participants into three categories for each vignette based on the bias they exhibited: a positive self-enhancement bias, no bias, and a negative self-enhancement bias.

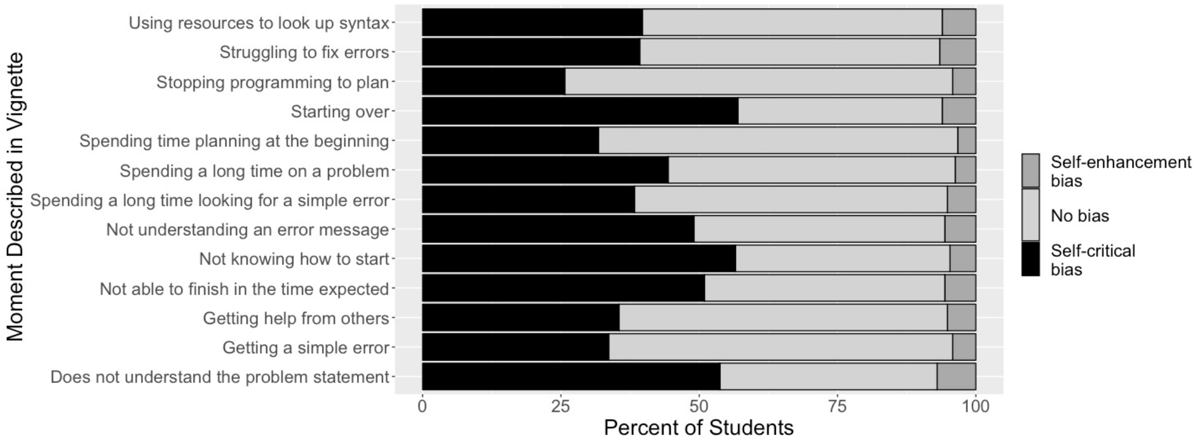

Figure 1. Graph showing the percentage of participants who exhibited a self-enhancement bias, a self-critical bias, and no bias, when comparing their responses to the questions following each of the thirteen vignettes.

Surprisingly, we found that very few students exhibited a self-enhancement bias. As shown in Figure 1, only 3-5% of participants had a positive self-enhancement bias for each question, while 25-60% of students had a negative self-enhancement bias. For the rest of this paper, we refer to a negative self-enhancement bias as a *self-critical bias*. Overall, these findings suggest that CS1 students tend to be more critical of themselves than of others, which is surprising given previous findings on the prevalence of self-enhancement biases.

This self-critical bias could manifest in two ways. Students could believe that both they and the character were performing poorly or well, but to different degrees (e.g. *slightly agree* for the character, *agree* for themselves). Or they could believe that they are performing poorly (e.g. *slightly agree*) but make no negative assessment of the character (e.g. *disagree*), or vice versa. To capture this second type of bias, we counted how often participants' responses to the two vignette questions fell on different sides of the Likert scale for each vignette. We found that 85% of students negatively assessed themselves but not the character for at least one vignette, while only 18% of students assessed the character but not themselves for at least one vignette. This effect was most common for the moments *starting over* and *does not understand the problem statement*, in which 35% and 33% of students respectively assessed themselves but not the character negatively. These findings show that a significant number of students negatively assess themselves at moments that they think are acceptable for others.

Self-critical bias is stronger when the student or the vignette character is female

Next, we analyzed whether self-critical bias was influenced by gender. We used non-parametric methods because the Shapiro-Wilk test showed that our data has a non-normal distribution. For the remaining analyses, we did not include the five students who reported non-binary gender identities because we feared the size of the group would result in an inaccurate representation of their experience. For the binary students, we conducted a Mann-Whitney U test, and found that female students were significantly more likely to have a self-critical bias than male students ($Z = 3484.5$, $p < 0.001$), with a median bias of 0.46 for male students and 0.92 for female students.

Given the prevalent stereotypes that depict computer scientists as male (Master et al., 2016), we wondered if students would assess themselves differently in relation to female and male vignette characters. We averaged the self-critical bias that each participant reported for the vignettes with female characters and with male characters. Then, we compared these values using a Wilcoxon signed-rank test (nonparametric t-test) and found that participants were significantly more self-critical when the vignette character was female ($Z = 8688$, $p < 0.05$). The median self-critical bias was 0.57 when the vignette character was male, and 0.71 when they were female.

After finding that students are generally more self-critical in comparison to female vignette characters, we wondered if this effect is impacted by the gender of the participant. To answer this question, we conducted an Aligned Rank Transform (non-parametric ANOVA) finding that individually both the gender of the character ($F(1, 206) = 4.39$, $p < 0.05$) and the gender of the participant ($F(1,206) = 14.90$, $p < 0.001$) had significant effects on self-critical bias. However, we did not find a significant interaction between these factors ($F(1, 206) = 0.36$, n.s.). We often think of female students as being most affected by stereotypes about who belongs in CS, however these findings show that male students are also influenced by these narratives.

Discussion and design implications

This research aimed to study the differences in how students assess themselves and others in response to moments that arise during the programming process. Through a secondary analysis of our survey data (Gorson & O'Rourke, 2020), we found that very few students exhibit a self-enhancement bias in this domain. Instead, many students exhibit a *self-critical bias*, with 96% of participants rating themselves more harshly than the vignette character in response to at least one vignette. We also found that female students are significantly more likely to have a self-critical bias than male students, and that both male and female students are more critical when the vignette character is female. This research has a few limitations. Since our data is quantitative, we cannot explain why some students evaluate themselves more critically than the vignette characters. Furthermore, many factors beyond gender may influence self-assessments, including race, sense-of-belonging, and perceptions of professionals.

Given the established phenomena of self-enhancement bias in other domains, we were surprised to see the prevalence of self-critical bias for both male and female students in this context. We believe these findings have important implications for the design of CS1 curricula and interventions. For example, we previously argued that CS1 courses should explicitly teach about professional programing practices to help students develop accurate expectations (Gorson & O'Rourke, 2020). While this could help some students, our new findings suggest that some students do not view these programming moments as universal signs of poor performance. Instead, they view these moments as more problematic for themselves than for others. To better support this group of students, CS1 teaching staff could call attention to moments when students may be assessing themselves particularly harshly, and help students reframe their perceptions of these moments. Additionally, our findings reveal that students have a stronger self-critical bias when the vignette character is female, suggesting that the stereotypes about who belongs in computer science may lead students to have lower expectations of women. We believe this provides compelling evidence for designing diversity events and initiatives that help both male and female students shift their expectations to see women as belonging and excelling in computer science.

Understanding Students' Representations of Mechanism through Modeling Complex Aquatic Ecosystems

Zachary Ryan, Joshua Danish, Cindy E. Hmelo-Silver
zryan@iu.edu, jdanish@indiana.edu, chmelosi@indiana.edu
Indiana University, Bloomington

Abstract: This study examines how 5th grade students represent the mechanisms of a complex aquatic ecosystem in the Modeling and Evidence Mapping Environment (MEME), a software tool designed to support students in iteratively modeling the elements within a complex system, and their relationships to each other. We explore the various ways students represented mechanisms of an aquatic ecosystem through their models and present our findings on the patterns that emerged and the unexpected ways that mechanisms were utilized within student models.

Keywords: modeling, mechanistic reasoning, science education, complex systems, CSCL

Introduction

Modeling is a difficult practice for young students (Pierson et al., 2017), but is also important in contexts where relationships between elements of a phenomena are unclear, such as in complex systems. An increasing amount of research demonstrates that elementary students can learn and engage with complex systems concepts (Hmelo-Silver & Azevedo, 2006; Danish, 2014; Yoon, Goh, & Park, 2015). When modeling a complex system, it is particularly important for learners to explore and represent the underlying mechanisms rather than just the superficial or surface-level details (Russ et al., 2008).

This study is part of a larger project Scaffolding Explanations and Epistemic Development for Systems (SEEDS), which aims to understand how fifth grade students engage with disparate forms of evidence as they explore complex aquatic ecosystems through modeling. To support these modeling practices, we developed the *Model and Evidence Mapping Environment* (MEME): a software tool that helps students create a simple model of a complex system (Figure 1).

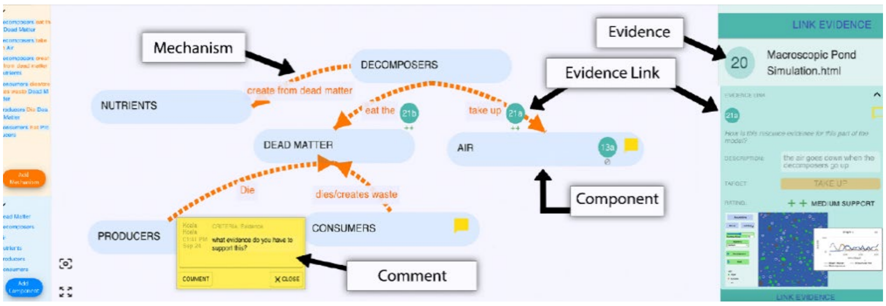

Figure 1: Screenshot of the MEME Software

The aim of this study is to examine how students represent mechanism when modeling complex aquatic ecosystems in MEME. In doing so, we seek to answer the research question: how are students representing mechanisms in different ways within MEME? Are these ways of representing mechanism being recognized and validated by peers?

It has been shown that young students can engage with and develop nuanced understandings of complex systems, such as the water cycle and honeybees working together to obtain nectar (Danish, 2014; Hmelo-Silver et al., 2015). Prior research has shown that the *Phenomenon-Mechanism-Components* (PMC) conceptual framework can aid students in attending to key dimensions of systems as they attempt to model it (Hmelo-Silver et al., 2017). Models that align with the PMC framework explicitly represent complex systems through the combinations of various **components** within a system, and represent the relationships between them through descriptive **mechanisms**, resulting in the **phenomena** being investigated.

Methods

This study was conducted as a five-week long unit with a grade five classroom of 20 students (15 boys and 4 girls consented) at a public elementary school in the U.S.Midwest in the spring of 2020. Students worked in dyads together in the MEME software to iteratively build models and look at evidence. Students also participated in an activity where they reviewed two other groups' models, and left critiques through MEME's commenting feature. While we intended the project to continue past this activity, we were cut short due to the Covid-19 pandemic.

Data for this analysis consists of the final models students completed. We coded students' models in two passes and looked closely at video data capturing the creation of mechanisms in models, and the interactions between peers that produced them. The first pass at coding involved looking at the isolated mechanisms (arrows) of each of the nine final models created in MEME. On this first pass we developed four codes based on Pierson et al.'s (2017) conception of learning progressions of scientific modeling. Our codes were adapted to fit 5th grade students and ranged from 0-3 for the intricacy of mechanism (see Table 1).

Table 1: Table of codes adapted from Pierson et al. (2017) used in analysis.

Code Level	Description
(0)	Mismatch between the mechanisms and components of the model, where the mechanistic explanation could not be interpreted in the context of the model.
(1)	Just an arrow being made to connect to components, with no mechanistic reasoning provided to why they might be connected in the system.
(2)	Some explanation provided for the mechanism but illustrated a vague sense of explaining the relationships beyond the source and target component.
(3)	Representation of a mechanism to explain the underlying relationships of the complex system, often supported by forms of evidence.

In examining the models, we noticed that students often captured robust mechanisms but did so using multiple unlabeled arrows. In looking at the level (1) codes across the models, a pattern emerged wherein students expanded their mechanistic reasoning by combining multiple components connected with unlabeled mechanisms. Therefore, we created two additional codes for a second pass, which we called expanded level (2) mechanisms, and expanded level (3) mechanisms. We unpack how this emerged in the findings below.

We utilized interaction analysis (IA; Jordan & Henderson, 1995) to carefully examine the interactions between peers surrounding the critique of coded level (3) mechanisms, including the expanded level (3) mechanisms. We looked closely at whether students appeared to understand their peers' mechanistic reasoning represented in their models. In these instances, we examined what occurred when the mechanism was understood by critiquing students, as well as what was happening where students failed to recognize their peers' mechanism when coded as level (3). Our results below outline the patterns that emerged in both the creation of mechanisms in modeling, and students' interpretation, or lack thereof, of peers' representations of mechanism across models.

Findings

The results of our coding (Table 2) showed that students ranged in their complexity in representing mechanism across their final models, and that while it appeared that the intricate level (3) codes were sparse on the first pass, they ended up emerging nearly as often in the second pass. Our second round of coding revealed multiple causal mechanisms represented through chains of level (1) codes and components where students conflated mechanisms as components of their models. The most common of these were three interconnected components with two unlabeled mechanisms, where the middle component represented either a level (2) or level (3) mechanism explaining the relationship between the other two components. Our results from the second round of coding found 10 expanded level (2) codes, and 18 expanded level (3) codes across the nine models.

Table 2: Results of the two rounds of coding

Coding Pass	Level 0	Level 1	Level 2	Level 3
1 (Simple Mechanisms)	5	28	29	16
2 (Expanded Mechanisms)	0	0	10	18
Total	5	28	39	34

Across models, level (2) mechanisms tended to be the first connections created by students in their simplified models containing just a few components at the start of the modeling activities (Figure 2). As time went on, level (3) mechanisms began to emerge, but so did many of the level (1) mechanisms of blank arrows. Many of these level (1) components connected chains of components formed the expanded level (3) mechanisms.

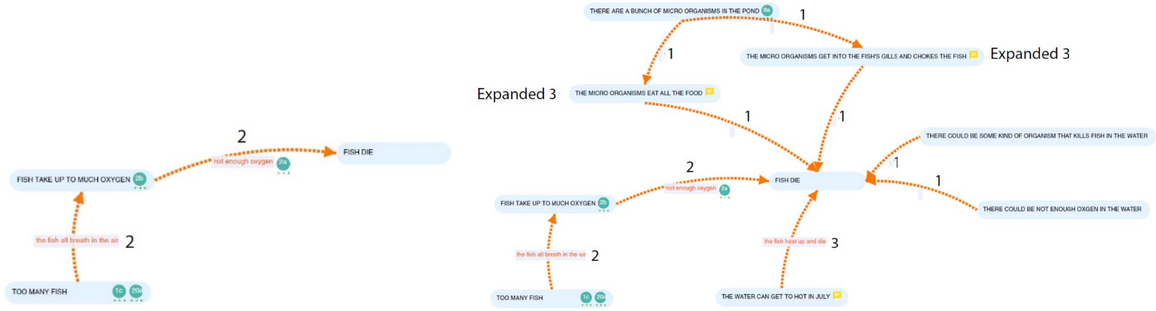

Figure 2. One group's initial (left) and final (right) model pulled from MEME with their mechanisms labeled.

Within interaction students tended to reference their resource library for a specific piece of evidence to support their reasoning before creating a component or mechanism that would end up being coded as a level (3). For example, in the model above (Figure 2), the students looked at one piece of evidence that cited the existence of microorganisms within ponds. They created the component "There are a bunch of microorganisms in the pond" and cited their evidence. The group then created two competing ideas to why the "fish die" because of this. Two additional components were created, "The microorganisms get into the fishs gills and choke the fish" and "The microorganisms eat all the food" and connected to "fish die" through unlabeled mechanisms. These two were coded on the second round as expanded level (3) mechanisms to explain the relationship between the "microorganisms" component and fish dying in the pond. A similar pattern emerges across students' models.

Despite the overall prevalence of level (3) mechanisms within models, they ultimately went unnoticed by peers in their feedback. In the example above, students never commented on any of the level (3) mechanisms, and only ever critiqued expanded level (3) mechanisms as not being labeled. This suggests that student peers may not recognize the representations of high-level mechanisms in scientific models. These instances within and across models reveal that while young students are fully capable of engaging with these complex phenomena, they further scaffolding to productively participate in these expert practices and to help distilling their complex thoughts about systems in precise ways to represent system mechanisms.

Discussion

Our findings revealed that students' models produced unexpected ways in which complex mechanistic reasoning was represented in their models, but ultimately went unnoticed by student peers. These patterns of model construction show that while students' mechanistic reasoning develops along a learning trajectory as they engage with iterating on models of complex systems, they still tend to conflate the concepts of **component** and **mechanism** when engaging in modeling. This may be an indication that students' representations may degrade in clarity as their model and the evidence they work with becomes increasingly complex as they iterate but didn't take the time to refine. Continuing to attend to the ways in which young students represent mechanism in models in ways that their peers can explicitly interpret them, we can further develop scaffolds to promote deep engagement with complex systems concepts for elementary students.

University of Haifa

Abstract: Multiple document comprehension is a challenging task that involves evaluating, selecting, organizing, and connecting sources and their claims. In this paper, we examine how 9th grade students utilized a digital document mapping scaffold to visually represent multiple scientific documents. Analysis of students' document maps revealed that most students were able to use the scaffold to appropriately evaluate documents' sources, represent the main claims that emerged from the documents, connect these claims to their respective sources, and identify agreements and disagreements between sources. However, some students focused more on constructing a highly elaborate representation of document claims, whereas other students focused more on integration of the documents through representation of the network of connections among sources and claims. These findings suggest a potential trade-off between elaboration and integration processes in multiple document comprehension that may require instructional attention and support.

Introduction

We live in an era which information is highly accessible and increasingly diverse. Consequently, students need to be able to construct knowledge and make informed decisions using multiple information sources or documents. Central challenges in comprehension of multiple documents are understanding the relations between the documents, making sense of their overall meaning, and reasonably weighing claims using reasons and evidence from the documents and in light of the trustworthiness of their sources (Barzilai & Ka'adan, 2017).

According to the Documents Model Framework (Britt & Rouet, 2012), in order to form an integrated understanding of multiple documents, competent readers create a *documents model.* This model includes two interconnected components: an *integrated mental model* and an *intertext model*. The integrated mental model is an internal representation of the situations or phenomena described in the texts, including their overlaps and inconsistencies. The intertext model involves a representation of the sources of the documents (including their positions, trustworthiness, etc.), the connections between sources and their contents (source-content links, who said what), and the connections between the sources (source-source links such as addition, support, or opposition). Connecting the contents of the documents to their respective sources enables readers to make sense of the differences between the documents and to weigh their claims in light of source characteristics.

Multiple document comprehension poses many challenges to students. Because information is spread over separate documents, students can find it difficult to recall information from previous documents and form cross-textual connections (Britt & Rouet, 2012; Goldman et al., 2012). When selecting documents and information, students may tend to choose according to fit with their prior knowledge, rather than according to source trustworthiness (Bråten et al., 2018). Students may also have insufficient meta-epistemic understanding of evaluation and integration strategies and criteria (Barzilai & Ka'adan, 2017).

Visual organizers and maps could potentially help students integrate multiple documents. Mapping may support comprehension of multiple documents by reducing the lower-order cognitive demands that characterize integration tasks and enabling high-order processing (List, 2019). Mapping can also cue construction of links among documents and increase students' understanding of how different ideas relate to each (Barzilai et al., 2020).

Nonetheless, relatively few prior studies have examined how students map multiple documents. Kiili (2013) found that construction of an argument map led high-school students to spend more time on integration and increased their awareness of the relations between arguments. Barzilai and Ka'adan (2017) found that using a paper-and-pencil integration map had a positive effect on middle-school students' integrative essays. List (2019) found that undergraduates were more successful in representing multiple texts through diagrams then through written essays. Specifically, the visual diagrams reflected more intertextual connections and citations.

A limitation of generic mapping tools is that they do not support construction of documents model elements such as source evaluations, source-content links, and source-source links. This led Barzilai et al. (2020) to develop an online learning environment called the Knowledge Society Sandbox which includes a document mapping scaffold that was designed to support construction and representation of documents models. Barzilai et al. (2020) qualitatively described how students used the document mapping scaffold as they engaged in inquiry with multiple historical documents. The aims of the current study were to conduct a close analysis of students' document maps in order to examine how they utilize the document mapping scaffold to represent multiple scientific documents. Our research question was: How do students use the document mapping scaffold to visually represent multiple documents and what do their maps reveal about their multiple document comprehension?

Method

The sample included 40 9^{th} grade students, 21 girls and 19 boys, who studied in an urban junior high-school in the North of Israel. Participants individually performed two multiple document tasks using the document mapping scaffold. The scaffold enables students to evaluate source relevance and trustworthiness (on a scale of one to four), to identify the main claims that emerge from the documents, and to map the connections among claims and sources. Each source is represented using a round source node. The size of the source node represents the relevance level, and the color of the source node represents the trustworthiness level. Each claim is represented as a blue rectangular node ('claim box'). There are three types of connections available: source-source links, source-claim links, and claim-claim links. Each link can be marked as a reference (black), support (green), or opposition (red) link. Examples of document maps are available in the findings section.

Before the first task, students watched a ten-minute video tutorial which demonstrated how to use the document mapping scaffold. In the first task, students examined if chocolate is healthy using five documents. In the second task, which took place about a week after the first task, students were asked to answer the question: "Is drinking bottled mineral water healthier than drinking tap water?" using seven documents. In this paper, we focus on analysis of the document maps created in the second task because this was a more complex task that was performed after the students were well familiar with the mapping tool.

The water bottles task included seven adapted online documents. Two documents presented arguments for drinking bottled mineral water, four presented arguments against this, and one document discussed the environmental impact of plastic bottles and had low task relevance. Three documents were published by trustworthy expert science or government sources, three documents had low trustworthiness (two were published by sources with explicit commercial interests and one was a personal blog with questionable credentials), and one source had a medium level of trustworthiness (popular science magazine). Students were asked to evaluate source trustworthiness and relevance, to map the documents, and to write essays that addressed the inquiry question.

Analysis of the maps that students created was informed by the Documents Model Framework (Britt & Rouet, 2012). We counted all claim boxes, source nodes, and links that appeared in students' maps. Claims were coded as *intratextual* if they were connected to only one source, and as *intertextual* if they were connected directly or indirectly to more than one source. We also coded whether the claim boxes included macro-claims or reasons for each of the positions presented in the documents (for or against bottled mineral water). Links were coded as *intratextual* if they connected a single claim to its source, and as *intertextual* if they connected two sources, if they connected a source to an intertextual claim, and if they connected claims from different sources or intertextual claims. We also coded agreements and disagreements between sources as follows: Sources were coded as *agreeing* with each other if they were directly linked using a support link or if they both supported or both opposed the same claim. Sources were coded as *disagreeing* if they were directly linked using an opposition link or if they had different relations to the same claim (support vs. opposition).

Findings

Representation of sources and claims

The maps included 5.33 (SD =1.79) source nodes on average out of 7 available sources. The mean trustworthiness rating of the three sources that had low trustworthiness was lower than the mean trustworthiness rating of the three trustworthy sources, $M = 2.28$, $SD = 0.53$ vs. $M = 3.53$, $SD = 0.42$, $t(39) = 11.88$, $p < .001$, $d = 1.88$. The relevance rating of the irrelevant source was lower than the mean relevance rating of the relevant sources, $M = 1.65$, $SD = 0.92$ vs. $M = 3.05$, $SD = 0.45$, $t(39) = 8.77$, $p < .001$, $d = 1.39$. This indicates that students were generally able to discern and appropriately represent source trustworthiness and relevance in their maps.

The maps included 5.73 ($SD = 3.88$) claim boxes on average. Most claims were intratextual claims ($M = 3.98$, $SD = 4.26$). Less common were intertextual claims ($M = 1.75$, $SD = 1.35$), $t(39) = 2.82$, $p = .007$, $d = 0.45$. Nevertheless, 75% of the maps included at least one intertextual claim. Furthermore, 77.5% of the maps included a representation of macro-claims and/or reasons both for and against water bottles. Although only few of the maps represented a full two-sided argument including macro-claims and reasons for both positions (17.5%).

Representation of connections between sources and claims

The maps included 9.53 (SD = 4.71) links on average. Students created more source-content links than source-source links, M = 7.43 SD = 4.44 vs. M = 0.68 SD = 1.31, $t(39) = 8.99$, $p < .001$, d = 1.42. They also created significantly more intertextual than intratextual links, M = 6.38, SD = 4.12 vs. M = 3.15, SD = 3.54, $t(39) = 3.36$, p = .002, d = 0.53. Additionally, the maps represented 2.93 agreements (SD = 3.11) and 1.33 disagreements (SD = 2.29) between sources on average, indicating that students were able to represent relations between sources. Interestingly, agreements were represented more often than disagreements, $t(39) = 3.50$, p = .001, d = 0.55.

Integration vs. elaboration in students' multiple document representations

Students' maps were diverse. Some included only a few intertextual claims that were connected to multiple sources, and some had many intratextual claims and relatively few intertextual connections. Figure 1 charts the maps according to their level of elaboration and integration. The X-axis represents the degree of elaboration based on the amount of claims in the map. The Y-axis represents degree of integration based on the amount of intertextual links in the map. As can be seen in Figure 1, some maps had low or zero integration, although a few of these maps were highly elaborated (e.g., map a). Some maps had high integration and relatively low elaboration (e.g., map b). Few maps were both highly elaborated and integrated (e.g., map c). We next take a closer look at these three maps.

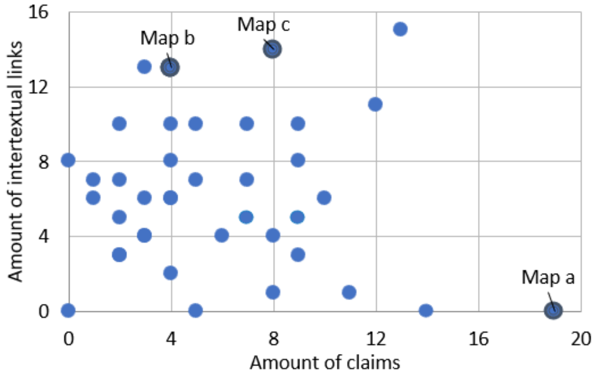

Figure 1. Integration vs. elaboration in students' documents maps

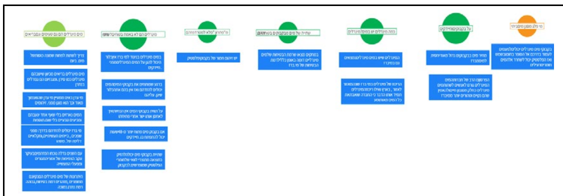

Figure 2a. Map 1: High elaboration and no integration

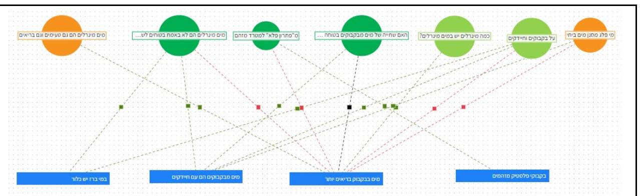

Figure 2b. Map 2: High integration and low elaboration

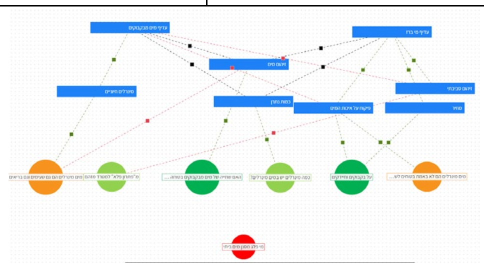

Figure 2c. Map 3: High elaboration and high integration

Figure 2. Examples of students' documents maps.

Map a (Figure 2a): High elaboration and no integration. This student extracted multiple claims from the documents and placed them under their respective source nodes in a table-like format. The map did not include any intertextual claims or links, suggesting that the student did not engage in integration. In terms of the documents model framework, this map represented connections between sources and contents, but did not represent source-source connections or an integrated model of the contents. Such a representation precludes weighing claims in light of breadth and strength of support.

Map b (Figure 2b): High integration and low elaboration. This student created one macro intertextual claim ("bottled water is healthier") which was linked to all seven sources. Four sources were linked using opposition links, two were liked using support links, and one using a reference link, clarifying that the claim that bottled water is healthier than tap water was disputed more than it was supported. However, this map had only three additional claims, two of them intertextual and one intratextual. Thus, although the map was highly integrated, it represented a relatively low number of ideas from the documents.

Map c (Figure 2c): High integration and high elaboration. This map had many direct and indirect links between sources and claims as well as fair amount of content representation. This student placed two macro intertextual claims on the top of the map ("bottled water is better" and "tap water is better"). In the middle layer of the map, the two macro claims were connected to six intertextual and intratextual claims. These claims were in turn connected to a row of sources on the bottom of the map. This student judged one source as highly untrustworthy (red source node) and placed it beneath all other sources. This source (a Facebook post by a commercial company) was not linked to any claims, indicating that the student decided not to integrate it.

Discussion

We found that students were able to construct rich documents models using the online document mapping scaffold. The maps revealed that most students were able to discern source trustworthiness and relevance, to identify claims from the texts, and to construct intertextual claims. Most students were also able to connect claims to their sources and to identify relations of agreement and disagreement between the sources. Students were not provided any direct instruction other than a brief tutorial on how to use the scaffold. This suggests that the representational affordances of the scaffold supported construction of documents models.

Students represented more source-claim links than source-source links. Source-claims links may be easier to grasp because the proximity of content and source information in the documents. Source-source links require forming inferences across documents and may also be more abstract. When students represented relations between sources this was mostly done by connecting sources to the same claim. Students represented more agreement relations than disagreement relations between sources, suggesting that they focused more on identifying similarities than differences.

Students had diverse approaches to mapping. Some focused more on elaborating the content of the documents, while others focused more on integrating the documents. Relatively few students constructed maps that were both highly elaborated and highly integrated. These findings suggest a potential trade-off between elaboration and integration processes in multiple document comprehension. This trade-off might be due to the high complexity of constructing coherent documents models. Different mapping approaches might also be due to students' perceptions of the aims of the map: Some students may view the map as a tool for gathering content from the documents, whereas others might view it as a tool for understanding how multiple sources relate to competing claims.

To conclude, the results indicate that a visual document mapping scaffold can support construction of documents models. However, students may need additional soft scaffolds that will adaptively draw their attention to various dimensions of representation, so that they can create well-integrated and elaborated documents models.

Computational Thinking as a Context for Ambitious Math Instruction

Margaret Walton, Janet Walkoe
mwalton@umd.edu, jwalkoe@umd.edu
University of Maryland College Park

Abstract: Current efforts to improve math education often call for *ambitious math instruction*, which promotes student thinking and conceptual understanding. Such instruction can be difficult for many teachers because it differs from how they learned math. Incorporating computational thinking (CT) into math teacher education might support teacher learning of ambitious math because it moves teachers out of their familiar math context. We use data from a middle grades math and science methods course to show how some pre-service teachers tend to focus on ambitious math goals to make sense of CT and its connections to math.

Introduction

In math education, many have sought to improve K-12 mathematics through *ambitious math instruction*. Ambitious math instruction promotes student inquiry, communication of mathematical ideas and connecting different math content (NCTM, 1989). Yet, many teachers struggle to teach according to ambitious math practices because it asks them to think about math differently than how they were taught (Ball, 1988; Borko et al., 1992).

One way to help teachers shift toward ambitious teaching might be to change their familiar math context. Computational thinking (CT), which is currently expanding in schools, might be that context change. CT includes the skills and ways of thinking in computer science and uses practices like pattern recognition and abstraction (Grover & Pea, 2013). Engaging students in such practices are also goals of ambitious math. By incorporating CT into an undergraduate math and science methods course, we noticed that pre-service teachers (PSTs) often focused on these practices as they learned about CT. Based on our observations of PSTs, we posit that including CT in math teacher education might be a helpful context for learning about ambitious math instruction.

The purpose of this paper is to discuss the possible affordances of CT to teach teachers about ambitious math. We first review the literature on ambitious math and CT and how they overlap. We then use data from a middle grades math and science methods class to show that PSTs seem to center ambitious math practices and goals in a CT context, making CT a plausible path for developing teachers' ambitious math instruction.

Background

Ambitious math instruction calls for teachers to engage students in solving open-ended problems, to facilitate math discussions, and to guide students as they construct math ideas (Fennema et al., 1993). The goals include helping students to reason mathematically, make content connections, and communicate their thinking. Standards like the Common Core State Standards for Mathematical Practice (SfMPs) reinforce these goals (CCSS, 2010).

However, it can be difficult for teachers to learn and use ambitious teaching. Many teachers learned math through traditional instruction that involves procedure memorization and routine problem solving. Shifting to ambitious teaching often asks teachers to rethink how math is learned and taught (Ball, 1998; Borko et al., 1992).

While most research promotes ambitious instruction in the current school math context, another path might be through CT. There are differing definitions of CT, but it is generally thought of as the practices and strategies used in computing (Grover & Pea, 2013). Many have worked to define CT in the context of education (Barr & Stephenson, 2011; Dong, et al. 2019; Weintrop et al., 2016). For example, in their teacher-friendly CT framework known as PRADA, Dong et al. (2019) defined the key components of CT as (1) pattern recognition, which is using patterns in meaningful ways; (2) abstraction, which is determining the general properties of a problem that are useful; (3) problem decomposition, which is breaking a problem into tractable component parts; and (4) algorithmic thinking, which involves solving a problem through a series of steps. CT can give students technological skills and can help to develop dispositions like persistence in problem solving and the ability to collaborate (CSTA & ISTE, 2011; NRC, 2010).

Recently, there has been a push to expand CT in K-12 classes (White House, 2016). In addition, researchers have highlighted the role that math plays in science fields, like computer science, and have argued that math education should reflect this connection (NRC, 2013). In response to these calls, efforts have often examined possible areas of CT-math overlap (Fofang et al., 2020; Pérez 2018). For example, Pérez (2018) developed a framework to show how CT dispositions can support mathematical thinking. He also noted the potential for a CT context to help teachers maintain the cognitive demand of math tasks, which is important to ambitious math teaching (Stein et al., 1996).

Others have reported important differences between CT and math (Rich, et al., 2020; Tatar et al., 2017). In one study, Rich, et al. (2020) looked for intersections between CT ideas and mathematical thinking seen in the Common Core State Standards (CCSS). They found that CT and math thinking can intersect in ways that are productive for student learning, but that not all mathematical thinking skills correspond to similar ideas in CT.

The ways that teachers connect CT and math has also been a research focus. (Duncan et al., 2017; Rich, et al., 2019; Walton et al., 2020). For example, Rich et al., (2019) examined elementary school teachers' thinking on the connections between CT and the math they teach. They found that some teachers could relate CT practices and the SfMPs, which could be leveraged during CT professional development.

Efforts by Rich and others are a great start in understanding how math and CT connect. However, their work is primarily from a computing perspective; they aim to develop teachers' CT understanding to expand computing in classrooms. Bringing computing to more students is certainly a worthwhile goal, but we argue that CT can also be valuable from a math perspective, like for teachers' ambitious math learning. Pérez (2018) showed what a math perspective could look like in his discussion of CT as a context for task implementation. We build on this work as we describe how CT seemed to provide a context for PSTs to highlight ambitious math goals.

PSTs' identification of ambitious math goals in a CT context

The following examples were taken from data collected over two years in a middle grades (grades 4-9) math and science methods course at a large mid-Atlantic university. There was a total of 32 PSTs in the two years. The course included a three-class CT module aimed at introducing PSTs to key CT components and at helping them integrate CT into their instruction. Activities included reading practitioner-focused articles that introduced key CT ideas (Years 1 and 2), discussions about how CT connects to the SfMPs (Year 1), and discussions about how CT fits into math and science classrooms in general (Years 1 and 2).

In both course years, we recorded class discussions about CT and how it relates to math and science instruction. We also conducted semi-structured interviews with four PSTs (two in each year) at the conclusion of the module. The four PSTs were chosen because they made strong connections between CT and classroom instruction during discussions, and we wanted to explore their thinking further. The questions we aimed to answer were (1) How do PSTs begin to conceptualize computational thinking? and (2) How do PSTs begin to learn about CT practices in relation to teaching math? While reviewing the data, we noticed that PSTs often centered ambitious math goals when making sense of CT and connecting CT to their instruction.

The first example is from an interview with a PST named Amy that took place at the conclusion of the CT module in Year 1. Throughout the interview, Amy seemed to ground her understanding of CT in *pattern recognition*. Pattern recognition is an important ambitious math idea for connecting different math topics and for problem solving. Early in the interview, when asked if she had seen CT in any previous experiences, Amy referred to activities from her teaching methods classes. She said, "Well whenever I think of computational thinking, I think about patterns...kind of like what we did in class earlier today [with a math task]." She continued by discussing another math methods class and said, "I had seen those concepts of, like, building and constructing a pattern from something you observe."

Amy also made connections between CT dispositions and ambitious math goals related to student discourse. When asked how she thought CT related to the SfMPs, Amy connected the CT ideas of *negotiation* and *consensus building* to SfMP3, *construct viable arguments and critique the reasoning of others*. Amy said,

> Collaboration and consensus building...ties into this other practice of constructing arguments and critiquing… Students should engage with their peers and if they're given a task where it's not so straight forward, then they should be having discussions where they say, "Hey this doesn't look right," or, "I agree with you because," or, "I disagree with you because…" And it ties into [SfMP3] because there's a collaboration of students working together and negotiation of what's actually correct, and from that cooperation and negotiation they build a consensus.

Here, the terms *negotiation* and *consensus building*, important to the CT disposition of collaboration, came from one of the articles PSTs read during the CT module (Barr & Stephenson, 2011). Amy connected collaboration with students critiquing each other's ideas, an important ambitious math practice and part of communication in mathematics.

Similarly, Cara, another student in year one of the course, related the CT idea of *abstraction* to SfMP6, *attend to precision,* when asked to make connections between CT and the SfMPs. In her interview, she said,

> The goal of abstraction in CT is to take something that's very complex and muddled and make sense of it, which relates to Standard Six because attending to precision… it's very difficult to communicate your thoughts clearly and precisely to others when in your head you're like, "Oh, this does that with this number…" In your head it's different from what you actually verbalize to your classmates...so I think that's how they're related because abstraction is trying to understand and make clarity of a situation.

Like Amy, Cara focused on the importance of being able to communicate mathematical ideas and saw the generalization involved in abstraction as helpful for that goal.

We also saw instances of PSTs identifying ambitious math practices in the context of CT with different PSTs in Year 2 of the CT module. It is important to note that in Year 2 PSTs were never prompted to make connections between CT and the SfMPs. One example again related to abstraction. After reading the practitioner articles, PSTs engaged in group discussions about what CT means and how what it could look like in K-12 classrooms. One PST, Jackie, said,

> I feel like [the articles] also talked a lot about… this is part of that abstraction, but generalizing a situation for problem solving. Because when you think through it you try to create this general situation where if you change factors about your problem you could still use that method.

Later in the class, she related this idea to deriving a general formula in math. She said, "If you show students the derivation, that's more of the process of how you get this generalized formula, but then they know the reasoning behind why they use a generalized formula and why their inputs will get the correct outputs." She later continued, "So students know why they can use that formula as a general rule for a specific type of problem." Here, Jackie showed abstraction could give students a better conceptual understanding of the math, while also giving them an appreciation of the power of using one formula for multiple situations, which are both aspects of ambitious math.

Discussion and conclusion

The examples above show some of the ways we saw teachers highlight ambitious math as they tried to make sense of CT. PSTs connected CT ideas, like pattern recognition, collaboration, and abstraction, to ambitious math goals like communicating thinking, critiquing others' reasoning, and building conceptual understanding. These observations are similar to Rich et al.'s (2019) findings that show that teachers can connect CT, the SfMPs, and other areas of their math instruction. Our work is notable because PSTs made these connections with and without prompting. This not only shows the potential for CT to reinforce ambitious math standards in math instruction, but also that teachers may tend to naturally incorporate ambitious math practices into their CT lessons.

Rich et al. (2019) see CT-math connections as an entry point for teaching teachers more about CT. We see an additional benefit of supporting teachers' ambitious math instruction. Our examples of PSTs show that CT could also provide a context for teachers to focus on ambitious math goals. Current ambitious math efforts often try to support teachers' learning of these ideas solely in a math context. As seen in our examples, a more indirect approach that uses CT might be helpful because it takes teachers out of their math context, where their apprenticeship of observation (Lortie, 1975) could direct them toward traditional math instruction. Instead, CT might place teachers in a context where they can more readily focus on ideas related to ambitious math.

More work is needed to determine whether such an approach could be successful. Given that others have found that CT and mathematical thinking overlap in some ways but not others (Rich et al., 2020), future studies could examine whether there are more or less productive ways that CT can support ambitious math. In addition, while the PSTs here highlighted ambitious math in the context of CT, our work does not address how teachers would develop instructional moves that would achieve such goals. Future work could look at how teachers' focus on ambitious math goals in a CT context might be leveraged to also support instructional practices.

Finally, the increasing push to include computing in school disciplines, like math, adds to teachers' constantly growing list of responsibilities. It is important to consider how these additions benefit teachers and grow their current practice. In the case of CT, we think it could provide a valuable context for teachers to focus on ambitious math goals and develop their ambitious math instruction.

Learning with and through Evaluation as Social Practice

Joanna Weidler-Lewis, Colby College, jweidlerl@colby.edu
Jimmy Frickey, Trent University, jimmyfrickey@trent.ca

Abstract: Learning as social practice attends to the situatedness of learning and the co-emergence of persons and practices. We argue evaluation should be viewed from this same lens. We present findings from an evaluation project at a high school. Using the project as a case study, we show that evaluators make consequential boundary judgments that either restrict or expand what counts as legitimate knowledge in a given situation as well as whose stakeholder's interests are validated.

Introduction

A salient feature of the Learning Sciences has been—and will continue to be—how we design and organize for learning. Our interventionist approaches to research, such as design-based research (Barab, 2006) and formative interventions (Penuel, 2014), require us to embrace a vision of how we think the world *ought* to be. Our challenge is to make our normative decisions explicit by defining not only *how* we design for learning but more importantly *for whom, with whom* and *for what* of our endeavors (Philip, Bang & Jackson, 2018). In this paper, we analyze how the practice of evaluation and the role of the evaluator contribute to the design and organization of learning. More specifically, we argue that evaluation is itself a social practice enacting boundary judgments that shape practices and it ought to be leveraged to support expansive learning as well as the changes in learning for which we design.

Recognizing evaluation as a social practice is an extension of our view of learning as social practice (Holland & Lave, 2009). We take learning to be situated in activity, mediated by cultural tools, and inherently contextual (Lave & Wenger, 1991; Wertsch, 1998). Learning is an ontological process: a coming to be of valued persons, activities, and objects (Packer & Goicoechea 2000; Weidler-Lewis, Wooten, McDonald, 2020). This process is ongoing and never fully determined; we can analyze how practices and learning outcomes came to be, but we cannot know *a priori* what organizational features will prevail in the future (Latour, 2005). However, as participants in social practices our agency and decision making have the potential to shape and inform practices despite not determining them (Pickering, 2005). We intend to make explicit how theory driven evaluation as a social practice (Schwandt, 2018) plays a role in promoting certain valued practices over others and the consequential decisions an evaluator can make enhancing or denigrating learning related to a research project or a research practice partnership.

Researching evaluation as a particular form of participation in the design of learning contributes to our understanding of how valued and normative practices come to be. Evaluators are often bracketed off from research projects in order to provide an external assessment of the project. Such removal from the ongoing coordination of practice has the potential to contribute to the reproduction of dominant evaluative logics that serve the powerful at the expense of the powerless under the guise of neutrality (e.g., Boyce, 2019). Alternatively, embracing evaluation as being pivotal and consequential in the practices of designing for learning has the potential to create new opportunities for designing towards socially valued futures. In the subsequent sections, we further articulate our view of evaluation as social practice and the importance of judgments that provide the shape and boundaries to our designs. Drawing on data collected from administering and debriefing an evaluation survey in a newly formed and emergent research practice partnership (RPP) between the authors and an experiential learning high school, we highlight key decisions made as evaluators that became consequential in shaping how and what was taken up for future action and inquiry to guide the school's practice, and thereby influencing possibilities for learning and becoming. We conclude by suggesting further lines of inquiry into the social practice of evaluation.

Theory driven evaluation as social practice and boundary judgments

We draw on the scholarship of Thomas Schwandt (2018) to claim that evaluation is a social practice that affords our ability to make evaluative judgments (i.e., claims about merit, worth and/or significance). Theory driven evaluation (TDE) provides information about the performance of a program or practice while also reporting on how and why the program achieved these results in order to guide practitioner actions (Coryn, Noakes, Westine & Schröter, 2011). TDE holds that evaluative evidence should have both scientific credibility (i.e., trustworthiness, validity, and reliability) as well as "practical worth" for stakeholders to improve their practices (Chen, 2013). The inclusion of practical worth for stakeholders in TDE is seemingly aligned with learning practice theorists who recognize relevance to practice as an important criterion for rigor (e.g., Gutiérrez & Penuel, 2014). However, TDE is routinely conceptualized from cognitive perspectives that promote evaluative thinking, reasoning, and sensemaking as primarily individual accomplishments and ignore the myriad ways that evaluative decisions are made collectively and situated within particular contexts (Schwandt, 2018).

Schwandt (2018) identifies three reasons for understanding evaluation as social practice facilitated by an evaluator. First, the identification of facts to measure, and their associated value or worth in a program, generally unfold in an interactive process among the multiple stakeholders who come to agreement or point of view on which to evaluate an intervention, also known as "stakeholder-making." Second, extensive literature on sensemaking demonstrates that individuals are not lone actors but are rather situated in contexts that impact their choices and action. For example, in education, teachers' sense-making of policy standards and their subsequent classroom activities are shaped by their organization context (e.g., Allen & Penuel, 2014). Lastly, evaluation should have as its aim practical action such that the evaluator supports "we-judgments" spanning matters of facts and values to answer "what should we do?" Or in the case of learning: *how ought we design for learning?* When evaluation is seen as a social practice and a joint accomplishment of participation by the evaluator and stakeholder community, the decisions made by the evaluator must be analyzed not according to only abstract theory (be it statistical or otherwise), but rather, evaluator decisions should be analyzed within their embedded context and in relation to the practice seeking improvement.

In order to make evaluative decisions for practical action, we must engage in "boundary judgment making." Any given situation or context cannot be studied in its totality; a boundary judgment is a decision regarding what should be included in the given situation and what should be left out (Schwandt, 2018). Given that evaluation is a social practice including multiple stakeholders, boundaries are not set or given; they are negotiated through collective sensemaking and require normative reasoning. By critiquing multiple boundary judgments, we determine how to proceed. First, judgments are critiqued by invoking morality and asking if a given phenomenon (i.e., policy, program, strategy) is *good* or the *right* thing to be doing. Second, critiques consider alternative arrangements and what *should be* done rather than what is currently happening. Lastly, there is no single or correct answer to what boundaries in an investigation ought to be. Therefore, critique in boundary judgment making is important to: (a) "make sense of a situation," including its values, motivations, power structures, relevant knowledge, and moral bases as well as "to bear the consequences of what will be done, as well as what we may fail to do;" (b) "unfold multiple perspectives and promote mutual understanding," by recognizing how different individuals and groups frame situations differently; and (c) "promote reflective practice" through both analysis and change (Schwandt, 2018, p.132). Because as evaluators we embrace TDE as social practice and recognize the need for reflection in our practice, this research seeks to understand both "what are the consequential boundary judgments for learning we made during our evaluation?" and "who and what practices were served by these boundary judgments?

Background and methods

As mentioned in the introduction, this work stems from a fledgling RPP involving the authors and an experiential learning high school (ELS). Frickey, the internal coordinator of evaluation & monitoring enlisted the help of Weidler-Lewis to begin research endeavors into both school improvement measures at the local level and more robust inquiry into experiential learning writ large. The timing of our partnership coincided with the 25th anniversary of ELS and was an ideal time to collect data on former students regarding their high school experience. Prior to our work, no systematic follow-up of former students was conducted. Given our mutual goals of serving both ELS and the broader experiential learning community, we decided to survey former students using a combination of psychometric scales used in other educational contexts, items measuring attitudes towards ELS values, practices and other key school indicators, and a single, open-ended prompt for former students to share any information they felt pertinent to our endeavor. In developing the survey, we considered the possibility of creating a single measure of "experiential learning success" to be iterated on by the already validated psychometric scales we employed that could be used in varied experiential learning contexts. We considered our survey to be a pilot of such measure knowing that given limitations, the survey would primarily be used for ELS evaluation. Our purpose in this paper is not to provide an empirical analysis of the survey design, implementation, and/or results. Rather, we endeavor to use the practice of surveying former students and the process of stakeholder-making to underscore how we engaged in TDE social practice and the boundary judgments we made alone and in collaboration with ELS stakeholders.

The data for our analysis comes from email correspondence about the survey between the authors, design documents and notes regarding the survey, the survey itself and its findings, the evaluation report presented to ELS, and the notes and records of the presentation of survey findings to ELS stakeholders. These stakeholders included the head of school, the director of curriculum, the director of student services, the associate head of student services, the director of professional development, and the former director of professional development who had been an original founder of the school. For purposes of anonymity we do not attribute views to stakeholder role. We first coded our data deductively by analyzing them for boundary judgments according to 1) moral claims (i.e., that which is *right* or *good*), 2) claims about what *should* be occurring at ELS, and 3) claims that interpreted the situation in one of many possible ways that could have been interpreted differently. After coding, we, looked for emergent themes and explicit connections between our codes, the stakeholders, and the different positions the stakeholders held (Saldana, 2009).

We present our initial findings detailing consequential boundary judgments in our evaluation practice. We demonstrate that even though key stakeholders were identified at the outset, whose interests were taken-up—and therefore pursued—emerged in interaction. We show how deference to scientific credibility in TDE can easily usurp its practical worth. This work is still ongoing, as such, we consider it to be exploratory in nature in that we are trying to surface the important tensions in TDE as social practice that will foster further study in this area (Stebbins, 2001).

Findings

From the outset, proponents of social practice theory might be confused as to why we would employ a survey of psychometric measures to evaluate student "success" when such measures assume psychological and cognitive orientations to the world. Indeed, this was one of the first boundary judgments made collectively among the stakeholders insofar as we all agreed that a succinct survey with limited questions would be an ideal starting point to begin an evaluative relationship. Reasons for this decision included time and financial constraints related to gathering data prior to ELS's anniversary celebration. It is important to note, historically, ELS had a culture of eschewing most forms of quantitative data on students including not assigning students grades and instead favoring students' lived, experiential data. While such evidence demonstrating student success at ELS was documented in several book publications, little sustained inquiry existed for why some ELS students succeeded when others did not. All parties agreed a survey had the potential to reveal previously undocumented categorical differences (i.e., race, gender, cohort, etc.) with explanatory power for "success" in the ways we defined. The ELS stakeholders saw the potential for quantitative evidence to support their intuitions regarding categorical differences in students' experience. For example, such a survey might help explain why female students were more likely to graduate despite being more difficult to recruit. The survey might also provide insight into racial difference, which had been a concern of many but not all at the school. As evaluators, we saw the potential for creating a survey measure applicable in other contexts. However, our survey results did not yield any statistically significant difference in any demographic category on any of our items or constructs. As evaluators, we could attribute this lack of evidence to the small student population of the school (266 graduates over its 25 years), the overwhelmingly positive skew of the respondents, and other survey limitations.

While the survey yielded a plethora of descriptive statistics, its lack of any evidence for causal inference was taken up differently by the different stakeholders. For example, the lack of causal evidence seemed to support the historic view that experiential data should be favored over quantitative data, a view contested by current stakeholders. Others remained agnostic of the survey's usefulness, withholding judgment regarding its potential to compare results over time in relation to program initiatives, so it served its purpose as starting point for future comparisons. Another stakeholder thought the survey data was detecting or could with revision detect differences in student experience. This stakeholder examined the descriptive statistics for evidence to support what they (and many other students and staff) knew to be true and had other forms of evidence regarding the experiences of students of color. These differences no matter how small could and should contribute to the ongoing discussion at the school regarding both how to approach broader, national narratives of race as well as any direct incidents of racism. This stakeholder believed direct anti-racist programming was needed, a position not shared by all, and thus, quantitative data could provide further justification for this targeted programming. As the evaluators, we had the opportunity to contribute to the collective boundary judgment making regarding the survey's usefulness in supporting conversations on racism in education. However, because no causal inferences (e.g., $p<0.10$) could be detected from the survey, and because the survey skewed positive, we defaulted to "scientific credibility" as a reason to exclude discussions of students' racialized experience in ways productive for both this stakeholder and the community. Our unilateral judgment shifted the ways in which we constructed this stakeholder: we focused on the lack of causal inference (one aspect of knowledge present in the situation) rather than what other forms of evidence could or should be brought into our discussion that ultimately shape students' experience at the school. In answer to the question who was served by this boundary judgment, we conclude that this stakeholder was not, and likely neither were the students for whom they were advocating.

Discussion and conclusion

While our findings may be brief, we believe they offer the powerful conclusion that just as social practice views of learning guide learning designers to create expansive, rather than reductive, opportunities for learning, so too can evaluators and their evaluations support this cause. In order to do so, evaluators must recognize the ways in which their decisions and judgments hamper or enable reflective inquiry into the very practices they are purporting to serve. The stakeholders came together to support inquiry into understanding varied student experience and implicit in this coming together was a hope to have further answers to and further evidence for, "what should we do?" One stakeholder had evidence, including individual experience as a student, that they were bringing to the process of evaluation; we failed to legitimize it by limiting the discussion of 'evidence' only to the causal claims missing from the survey. We bounded the survey discussion to only include causal inference reliably shown in the survey data despite knowing the school legitimized many other forms of data and the survey could have been used to further those alternative conversations. Moving forward, our role in facilitating stakeholder-making is to continually ensure that we are accurately representing the mutual agreement among stakeholders and to whatever extent possible include multiple forms of evidence in addition to multiple stakeholder perspectives. Part of our evaluation practice, then, must include processes to reengage and reassess if and how our shared agreement has been sustained as well as what dominant logics persist at whose expense. Because stakeholder-making is an on-going practice, a productive line of future inquiry is to trace this process over time and continue to iterate on how best ensure a relationship of reciprocity that values and builds on each other's expertise.

Abstract: In this paper, we present a co-design study with teachers to contribute towards development of a technology-enhanced Artificial Intelligence (AI) curriculum, focusing on modeling unstructured data. We created an initial design of a learning activity prototype and explored ways to incorporate the design into high school classes. Specifically, teachers explored text classification models with the prototype and reflected on the exploration as a user, learner, and teacher. They provided insights about learning opportunities in the activity and feedback for integrating it into their teaching. Findings from qualitative analysis demonstrate that exploring text classification models provided an accessible and comprehensive approach for integrated learning of mathematics, language arts, and computing with the potential of supporting the understanding of core AI concepts including identifying structure within unstructured data and reasoning about the roles of human insight in developing AI technologies.

Introduction

Artificial Intelligence (AI) has become a ubiquitous facet of our daily lives. Our young generation should be given high-quality academic training and environments in which they are empowered to participate in the public discourse about AI (AI4K12, 2019; Zimmermann-Niefield et al., 2019). It is a challenge to position youth to be thought leaders in this public discourse without fostering an in-depth understanding of what exactly AI is, how AI works, and why and where AI is used.

Data is the raw material from which artificial intelligence is imbued in artifacts through design. Learning from data is the process through which an AI program gains its "intelligence", and one that we argue is critical for students to devote more focus to. The growing attention to data literacy in pre-college education (e.g., Haldar, Chopra, Wong, Heller, & Konold, 2018) has partially responded to this learning goal. However, the data literacy community has primarily focused on structured data, which has already been quantified and distilled into variables arranged in tables, ready for modelers to manipulate and analyze (Haldar et al., 2018; Lee & Wilkerson, 2018). What has been neglected is the highly consequential and highly subjective process of operationalizing those variables from unstructured and semi-structured types of data such as text, image, audio, and video. The ISLS research community has acknowledged the great deal of creativity, insight, and variation that can be brought to bear in this process of operationalization in its investigation into Multivocality (Suthers et al., 2013). The message of the active and iterative role that data analysts must play when applying modeling technologies is one that we as researchers must also remind ourselves about (Rosé, 2018). Modelers need to extract features that define a representational space in which meaningful distinctions can be made between subsects of instances that take on different significance within an application or a conceptual model. This is what it means for AI developers to do the work of making a prediction problem learnable (Witten et al., 2016). Identifying the iterative process of structuring data, building models, and troubleshooting them in order to understand what their weaknesses tell us about how the structuring needs to be adjusted are the core activities that developers of AI need to be educated in, and which we attempt to make accessible to students. These foundational data practices are critical for students to understand the role of human insight in developing AI technology, but currently are missing in k-12 education.

Much is unknown about ways to advance students' understanding of the above-mentioned core AI concepts. Built on earlier work on student engagement in data wrangling practices (Jiang & Kahn, 2020), this study aimed to evaluate an initial design of a text classification learning activity and explore possible ways to incorporate the design into high school classes, especially non-computing classes. We report a co-design study of a three-year design-based research program (Brown, 1992) that aims to create a high school curriculum powered by StoryQ to engage students in practices of modeling unstructured data. In particular, we guided teachers to test-drive (Penuel et al., 2007) a text classification learning activity using StoryQ prototype and conducted a semi-structured interview to elicit teachers' thoughts on the activity. Specifically, we examined:

1. How do teachers come to understand modeling unstructured data?
2. In what ways do teachers think modeling unstructured data can be integrated into their classes, especially non-computing classes?

Methods

Participants and context

Two teachers, Martin and Hector (pseudonyms), participated in co-designing the unit and technology. The research team met with them prior to the co-design session to discuss the project. Martin has taught ELA (i.e., English Language Arts) for 20 years and Hector had 21-year teaching experience in mathematics and computer science (CS). He was actively learning about teaching AI. We intentionally selected two teachers from different backgrounds as the curriculum will integrate the learning of mathematics, ELA, and computing. In addition, we envision that the curriculum will be co-taught by ELA and mathematics/CS teachers in future iterations.

The co-design session was conducted remotely via Zoom, a video conferencing tool, and included three sections: a five-minute introduction, one-hour clickbait activity, and one-hour semi-structured interview. We first described the goal of the co-design session and emphasized that teachers were expected to experience the learning activity as a user, learner, and teacher. Afterward, we walked teachers through our prototype and associated learning activities to understand how human and computer models determine whether a headline was a) clickbait for encouraging visitors to click on a link or b) news from professional news agencies. The clickbait activity was an exemplar topic for introducing text classification models. The prototype uses logistic regression over unigram features (i.e., single words) as the classification model, which allows predicting headlines into discrete labels by learning the relationship from a given set of headlines with actual labels. We chose it for our prototype as it is easy to interpret for novices and efficient to train (Witten et al., 2016). To solicit feedback, we conducted a semi-structured interview after the clickbait activity. In addition to the co-design session, teachers wrote reflections and contributed ideas about designing the curriculum and platform.

Data collection and analysis

We collected video recordings of the co-design session, including 1) teachers' interactions with the prototype when exploring text classification models to address RQs 1 and 2 and 2) their responses to interview questions to answer RQs 2 and 3. For analysis, we used interaction analysis (Jordan & Henderson, 1995), thematic coding (Braun & Clarke, 2006), and peer debrief. Three researchers developed analytics memos of video recordings, followed by peer-debriefing with four other researchers to ensure validity. Furthermore, we collected and coded teachers' written reflections and ideas throughout the project to gain more insights about their views of learning opportunities in modeling unstructured data and integrating the activity into high school classrooms.

Findings

RQ1: How do teachers come to understand modeling unstructured data?

We found that teachers' understanding of modeling unstructured data evolved after connecting human insight and computer decision making. First, Martin created a dot graph and then they discussed why a headline could be a clickbait or news based on their interpretation of the headline and prior knowledge. Since Martin had not interacted with the prototype and Hector used the prototype before, the research team asked Martin to share the screen. When reading and interpreting headlines, they wrote down rules (Martin typed based on discussions) for clickbait and news headlines and described the process of reading samples and generating rules as inductive reasoning.

Teachers then created a confusion matrix (Witten et al., 2016) to compare actual and predicted labels. Confusion matrix is a performance measurement for machine learning classification that compares predicted and actual labels in a two-dimensional array. As Martin described, "I'm immediately interested in all the ones that where the computer predicted incorrectly." In addition, he not only noticed errors from the computer model but also proposed how we could use the error as guidance to revise the model. Furthermore, Martin and Hector constantly drew on prior knowledge, such as equating the process of computer decision making as advanced search (e.g., headlines with superlative language were more likely to be clickbait).

After investigating the confusion matrix, Martin and Hector probed into computer decision making by creating a frequency and feature weight graph from the features table (Figure 1). They were prompted to investigate the graphs of a) distribution and b) frequency and feature weight together to understand where the weights came from. Martin clicked feature “you” (the highest positive weight, representing that a headline containing “you” would more likely be predicted as clickbait) in the frequency and feature weight graph. Immediately, they noticed that only one headline containing “you” was not clickbait in the distribution graph. While they wondered why it had the highest positive weight, the research team explained that the high proportion of clickbait headlines to news headlines containing “you” contributed to the high positive weight. They came to understand that the feature weight was related to the proportion of clickbait headlines to news headlines containing the feature in the training data, which is the dataset that we used to train a machine learning model. The clickbait activity ended with teachers discussing sources of error from features and possible ways to improve the model.

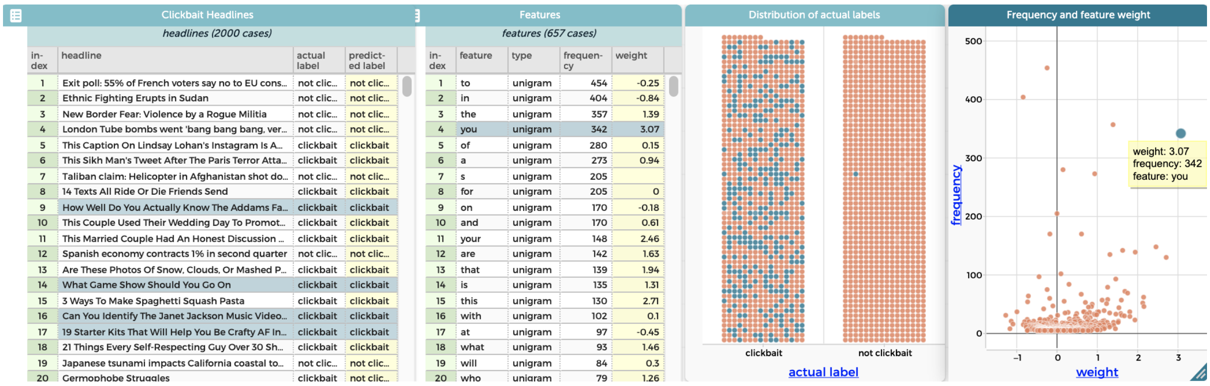

Figure 1. Features table (second) and graph (fourth). Unstructured texts needed to be converted to structured features for machine learning algorithms to exploit. One type of feature is unigram, or single word.

We can clearly see that teachers (in particular Martin, the ELA teacher) became highly engaged in reasoning about rules that computers could learn well, or not, such as the content. They developed an informal understanding of “feature” as “representation that the model can use.” In general, while they were comfortable with connecting human insight and AI models, proposing ideas for programming rules into AI models for text classification, they (especially Martin) needed further guidance to interpret graphs with mathematical reasoning and understand how learning weights on features works from a machine learning perspective.

RQ 2: In what ways do teachers think modeling unstructured data can be integrated into their classes, especially non-computing classes?

Martin and Hector identified learning opportunities from different perspectives. Martin emphasized different layers of learning in ELA, from word choice and sentence structure to interpreting broader contexts, such as historical contexts surrounding text producers. He mentioned that models with basic features (e.g., unigram) might not be able to predict themes of stories without adding advanced features related to information about writers of stories. In addition, he suggested engaging students in analyzing misclassifications (i.e., predicted labels are different from actual labels) within and beyond texts, such as history surrounding the text. In terms of Math and CS learning, Hector discussed that the activity could introduce students to graph literacy, mathematical reasoning, error analysis in rich contexts, and the importance of human insight in developing AI technologies.

Both Martin and Hector suggested leveraging the exploration of text classification models as an interdisciplinary learning approach. They described the learning activity as a focused data analysis of language and a comprehensive approach to and unique context for integrating STEM and the humanities. Also, as described earlier, they stressed the need of helping students to interpret text by drawing on knowledge beyond text. Martin further framed the exploration of models as an innovative way of addressing the criticism in ELA, “most of the language arts for the last 20 years or so have been a form of new criticism, they call it new criticism, where you analyze a text using only the data within the text.” From his perspective, when conducting error analysis, students could be guided to draw personal experience and knowledge about broader contexts to identify sources of error in computer models. In addition, he suggested integrating the activity into traditional writing lessons, such as having students write texts and using their writing as test data to measure model performance.

Discussion and implications

In this study, we examined how teachers began to understand models that were built from unstructured data and ways of integrating modeling unstructured data into their classes, especially non-computing classes. Specifically, the activity sequence of HCC (Human decision making, Confusion matrix, Computer decision making) created an exciting opportunity for participants to understand the role of human insight in developing AI technology as well as reasoning about computer decision making in rich contexts. The confusion matrix, in particular, triggered in-depth error analysis such as analyzing the severity, number, and types of errors that models might produce and how models could be modified by applying human intelligence. While teachers had rich discussions about computer decision making by referring to rules that they identified, they were confused about the feature table, including how models learned feature weights. In the next round of co-design, we will extend the HCC into HC**P**C sequence. **P** stands for adjusting **perspectives** on models and modeling (i.e., practicing the iterative process of updating rules based on insights gained through probing into the behavior of models). We expect that this modified activity sequence might help participants to reason about model performance from a machine learning perspective.

Notably, teachers drew on prior knowledge and personal experience in the discussions about texts and contexts surrounding texts. Future studies could examine other text classification tasks and strategies to create broadly inclusive learning experiences that engage participants from diverse backgrounds in expressing their cultures and personalities. Also, teachers rarely questioned where the dataset came from and who created the actual label. Having participants manually label a small data set and create labels for classification might support them in questioning modeling processes instead of assuming the objectivity of data science and that labels come from nowhere (D'Ignazio & Klein, 2020). In summary, this work contributes to the research on creating a scalable learning environment for high school students to participate in text mining practices in an accessible, relatable, and empowering way, develop understandings of core concepts including machine learning and unstructured data, and envision their own future lives that are centered on or powered by artificial intelligence.

Zooming In: Exploring the Construction of Professional Vision in Teachers' Reflection with Visualizations of Classroom Discourse

Andrea Gomoll, Sherice Clarke, Katherine Dennis
agomoll@ucsd.edu, snclarke@ucsd.edu, kadennis@ucsd.edu
University of California San Diego

Abstract: This paper explores one slice of a design-based research project (*ClassInSight)* that aims to support teachers' facilitation of dialogic discussions in secondary school science classrooms. Reviewing representations of discourse in their own classrooms via a desktop app, teachers reflect on the *when, how, and why* of facilitation moves and student contributions. This paper delves into one cycle of reflection and teacher learning. Teachers reflected on representations (at three grain sizes) of their own practice. We unpack teachers' reflection with visualizations that moved from percentages of student and teacher talk (coarse grain) to student and teacher turn taking (medium grain) to line-by-line transcript level detail (fine grain)—unpacking affordances and constraints of each representation of practice and using teacher voices to inform the design of personalized professional development.

Introduction

Teachers are constantly engaged in the work of constructing and enacting professional vision (PV) as they highlight specific features of their surrounding environment, interpret these features, and take action in real time (van Es & Sherin, 2007). An important mechanism of this PV is pedagogical reasoning (PR)—the sensemaking that occurs in planning, facilitation, and assessing student learning (Shulman, 1987). As teachers engage in PR and construct PV, they grapple with the *when, how, and why* of their actions. As they hone their craft, teachers have limited access to individualized representations of their own teaching and modes for reflecting on these representations (McNeill & Knight, 2013). This study examines the facilitation of science discussion and explores how reflection with a variety of visual representations of classroom discourse can support teachers' learning.

When teachers facilitate structured classroom discussions that foster shared reasoning, students benefit with steep increases in learning (Clarke et al., 2015). However, such discussion is rare, particularly in science classrooms that serve students from historically underserved backgrounds (Resnick et al., 2015). Prior research on teacher professional development has focused on equipping teachers with pedagogical content knowledge and discussion facilitation strategies, which is often abstracted from teachers' own contexts (McNeill & Knight, 2013). Few studies have generated robust evidence of how PD supports substantive changes in teachers' *discussion* facilitation (McNeill & Knight, 2013). We work to address this gap as we explore secondary science teachers' reflections with visualizations of their own classroom discussion. Further, we respond to recent calls for microgenetic studies of teacher learning (Walkoe & Luna, 2020)—attending to the interactional construction of PV (an indicator of teacher learning) as teachers engage with representations of their own practice.

Conceptual framework: Teacher learning

Our conceptual framework of teacher learning includes four iterative stages navigated by teachers: 1) pedagogical actions which are used to generate representations of practice, 2) noticing features of teaching, leading to 3) scaffolded reflection, which then grounds 4) data-driven planning for the next actions for discussion lessons. As teachers reflect, they may experience productive dissonance (c.f. Boekaerts & Corno, 2005) when expectations do not align with representations of practice. We conceptualize productive dissonance as critical for teachers' motivation to engage with their classroom discourse data and to make sense of it.

ClassInSight is a digital tool that can be used by teachers to reflect on facilitation of classroom science discussion and act on productive dissonance. The *ClassInSight* visualizations are designed to scaffold teachers' noticing, make visible dialogic aspects of classroom dialogue, and create space for goal setting. In this paper, we examine 12 secondary science teachers' reflections with three *ClassInSight* representations of practice (visualizations). We consider the affordances of these designs for supporting the development of robust science discussion and argumentation. We ask*: How is PV constructed in teachers' reflection with visualizations of their own classroom science discussions?*

Methods

As a design-based research (DBR) effort (Barab & Squire, 2004), our research team works alongside practitioners to develop solutions that work in specific contexts. We privilege teacher voices and work to co-design a model of teacher learning that is shaped by teachers themselves. To trace patterns in noticing, interpretation and response moves (key elements of PV), we use discourse analysis methodologies (Potter, 2012).

Participant demographics and data collection

Participants included 12 middle and high school science instructors in a school district in the Western U.S. These instructors teach within a district that serves a student population that is 60% Latinx, 28% White, 3% Asian, 4% African- American, and 5% of mixed ethnicity. The district reports 58% of students qualified for free or reduced-price lunch. Participating instructors include 5 high school instructors and 6 middle school instructors teaching a variety of science disciplines (e.g., general science, chemistry, engineering). Teachers range in teaching experience from 5 - 30 years.

We observed 12 class sessions flagged by instructors as experiences where they planned to have extended discussion. We recorded classroom audio and took detailed field notes. De-identified transcripts of audio data were coded by three researchers at the sentence level. Raters independently coded five lessons for features of classroom discussion (question and response moves) and achieved 91.3% agreement. Coded files were transformed into visualizations (accessible in the *ClassInSight* app) for teachers to reflect with, and researchers created individualized reflection session protocols for each teacher. 60-minute reflection session protocols included the teacher's visualizations, a set of open-ended questions about teacher noticings and interpretations, and a layer of researcher-selected noticings and interpretations. Reflection sessions were conducted with each teacher 2-4 weeks after the classroom observation. Data collected during reflection sessions included audio data, screencast data of teacher engagement with visualizations, and all artifacts referenced or created during the session.

Visualization design: Coarse, medium, and fine grain design principles

Our PD and visualization design builds on prior work that leverages representations of teachers' own practice and provides opportunities to break these representations down (e.g., Sherin, 2007). Our first iteration of visualizations focused on teacher and student question and response codes. Recognizing the important role of questioning, collaborative reasoning, and equitable participation in dialogic discussion (Michaels et al., 2010), we worked to capture open and close-ended questions and responses, student talk that connected explanation to evidence, and *who* was speaking *when*.

Visualizations occurred across three grain sizes—coarse, medium, and fine (Figure 1). We conjectured that these grain sizes could work together to scaffold noticing—providing moments of productive dissonance that could be reasoned about as instructors "zoomed in" from coarse to fine grain.

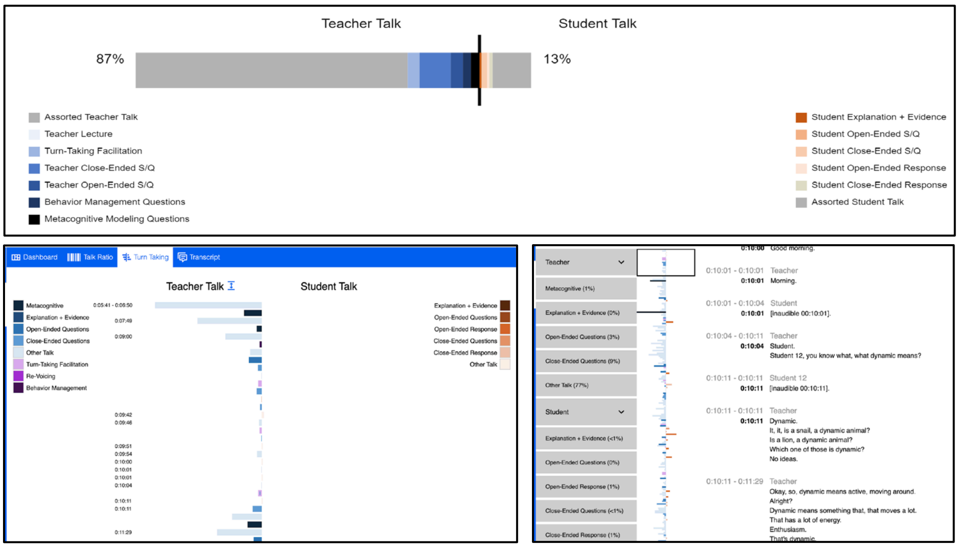

Figure 1. Representations of coarse (*top)*, medium *(left)*, and fine grain (*right) ClassInSight* visualizations.

At the *coarse grain level*, we designed for attention to *how much* teachers were speaking in relation to *how much* students were speaking as well as what kinds of talk moves occurred. Here, a bird's eye view of talk across a class period shows percentages of student and teacher talk—including a breakdown of question and response categories. Productive dissonance at this grain size might look like a recognition that there is more teacher talk than expected. At the *medium grain*, teachers are able to see classroom dialogue represented in turns (sequence and length)—supporting noticing around how talk time is exchanged throughout the class session and where extended exchanges between students might be occurring. Here, cause/effect relationships were also made visible (i.e., "when I asked X, I got Y"). At the medium grain, productive dissonance might look like recognition that there are unexpected sequences of talk (e.g., several questions asked with no student responses received). At the *fine grain*, we designed to support attention to what specific questions were asked and responses achieved, as well as reasoning around "why?" and "what if?" At this grain size, teachers are able to review classroom dialogue at the transcript level. At the fine grain, productive dissonance might look like recognition that a specific prompt was not taken up by students as intended.

Data analysis

This study centers on data collected from reflection sessions with our 12 participating teachers. Engaging in discourse analysis (Potter 2012), we iteratively explored how PV was constructed in teachers' reflection sessions—unpacking indicators of PV line-by-line. Transcripts of reflection sessions were memoed with attention to noticing, interpretation, and response moves. Salient extracts were collaboratively analyzed in a series of data sessions with research team members. We held additional data sessions to validate and elaborate upon themes and select representative extracts related to teacher PV trajectories across visualizations.

Findings

As teachers engaged with each of the three visualization grain sizes, a pattern emerged that helped us to understand the ways in which teachers' noticing and reflection were mediated by these visualizations. In the following section, we illustrate how PV was constructed and refined *across* grain sizes.

The coarse grain: Perturbation and quantitative goal setting

Reflecting with coarse grain visualizations, teachers made high-level noticings and set high-level goals grounded in these noticings. An emergent theme at this grain size was that teachers (nine out of 12) were quick to highlight disproportionate student and teacher talk, and often set goals around "talking less" and creating more space for student voices. As one middle school teacher, Sara, put it, "My first reaction is the gray is me talking, which seems like a really high amount. Too high." Here, Sara notices that student and teacher talk are disproportionate, and interprets this imbalance—a point of dissonance.

Beyond highlighting the amount of teacher talk at the coarse grain, teachers (10 out of 12) noticed absences of codes/discourse indicators that they hoped to see (e.g., the absence of student explanation that included evidence). We interpret this attention to absence as an indicator of productive dissonance. At this grain size, teachers' noticing generated a need for more information about the discursive interactions represented. In sum, high level visualizations created opportunities for perturbation—a precursor to deeper reflection and PV construction as "zooming in" occurs at the medium and fine grain sizes.

The medium grain: Noticing and interpreting the cadence of the class

At the medium grain size, teacher PV centered on the sequence of talk and cause/effect relationships between teacher and student discourse. Here, teachers got a sense for the flow of the class period as they scrolled through a timeline of student and teacher turns. Teachers also flagged specific points of interest within the lesson. For example, eight teachers highlighted specific exchanges where they were interested in the number of responses and/or questions that occurred within an exchange. Many requested more information about these exchanges in order to fully interpret how and why these sequences unfolded. This need for more information was a point of productive dissonance. With this view of classroom discourse, "zooming in" from the coarse grain, teachers noticed patterns of interaction. To further illustrate the kinds of interpretations made at the medium grain size, we present another extract from middle school instructor Sara.

After highlighting the point in the lesson where a video played, Sara scrolled before and after the video segment to explore student engagement pre- and post-video viewing. As Sara explored, she shared: "It's good that after that [the video played] there's a lot more student engagement...that [video] was a phenomenon. The purpose…is to get students asking questions… I can look at this and be like, 'it worked'...Because there's definitely way more students talking [after the video]." Here, Sara connects her noticings about student responses before and after an event (video viewing) to a pedagogical move (the introduction of a phenomenon). She attends to this visualization as a way to interpret if pedagogical moves were successful—with success defined here by the number of students making contributions. Sara uses evidence from the visualization ("more students talking") to support her interpretation. In sum, the medium grain afforded noticing and pedagogical reasoning around specific segments of classroom dialogue—attending to the sequential nature of interaction in ways not possible at the coarse grain level.

The fine grain: Attending to language and imagining alternative possibilities

Reflecting at the fine grain, PV construction included connection making across the noticing and interpretation moves that occurred at the coarse and medium grain sizes. Here, teachers reimagined specific pedagogical actions. Teachers were able to even further "zoom in" on the points of interest flagged at coarse and medium grain sizes—unpacking what happened and constructing narratives about *why* the dialogue unfolded in a turn-by-turn analysis.

For example, middle school math and science teacher Bill engaged in a reenactment of his practice as he reflected at the fine grain—reading aloud a sequence of his open-ended prompts and the student responses he received. Bill attended to one student response he received after a line of questioning posed to the whole class and noted: "Sure would be nice to have more than one opinion…I need to say, 'Is there another opinion?'" As Bill read, he echoed his noticing at the coarse grain (i.e., "there is less student talk than teacher talk"). At the fine grain this noticing was grounded in line-by-line interpretation—an affordance of the fine-grained visualization. Bill went on to consider alternatives to what unfolded in the episode he chose to explore in detail as he stated "I need to say, 'Is there another opinion?'" Here, Bill proposed a specific line of dialogue that may have shifted student participation. There was a kind of rehearsal as he verbalized possible moves—suggesting that the fine-grained level visualization can support the formulation of very specific facilitation moves.

Conclusions

As teachers moved across a trajectory of coarse to fine grain visualizations, their PV construction became increasingly nuanced. The flow of the visualizations functioned to put together the pieces of PV (*noticing, interpretation, and response).* As seen in the examples presented throughout the Findings, at the coarse grain, teachers generally noticed points of high-level dissonance ("I had no idea I talked that much!"). At the medium grain, these points of dissonance were positioned within the context of the "cadence of the classroom." As turn taking and the length and categorization of turns were visualized, teachers noticed specific points of interest and began to reason about what might have been happening. At the fine grain, these reasonings were confirmed, extended, or challenged, as teachers reviewed points of interest at the transcript level. Here, teachers also made the most fine-grained plans for shifts in future practice.

This work contributes to our understanding of how teachers reason with representations of their own practice. Further, the three grain sizes of representations of practice explored here, and the ways that teachers reflected with them, show promise for our emergent understanding of how PV construction occurs and can be scaffolded in personalized mediums that extend beyond more commonly used representations of practice (e.g., video and transcript).

"It's Working - We're Bosses" – A Study of Contentious Moments of Learning, Identity and Power in the Context of a Coding Project

Jrène Rahm, Université de Montréal, Canada, jrene.rahm@umontreal.ca
Ferdous Touioui, Université de Montréal, Canada, ferdous.touioui@umontreal.ca

Abstract: This study addresses how power issues are worked out in situ as youth engage in joint-meaning making and identity work in the context of a coding project at the crossroads of formal and informal science education. Based on an ethnographic case study of one team's forms of engagement in the coding project over the school year, we document shifts in participation and emergent relations with others, materials, and tools, and the manner these shifts are ethnically and politically laden moments of contentious moments of meaning making and becoming in STEM. We make evident how learner experiences and identity work are entangled with subtle ethnic, class, gender and linguistic differences, and in doing so, attend to power through a multilayered analysis of the coding project.

Problem

This study addresses how power issues are worked out in situ as youth engage in joint-meaning making and identity work in the context of a coding project at the crossroads of formal and informal science education. Building on work by Vossoughi et al. (2020), we are interested in documenting shifts in participation and emergent relations with others, materials, and tools, and the manner these shifts are ethnically and politically laden moments of contentious meaning making and becoming in STEM. We assume that learner experiences and identity work are entangled with subtle ethnic, class, gender and linguistic inequalities. We also build on the argument advanced by Philip and Gupta (2020), who note that shifts in activity systems make evident that "power is never fully deterministic" (p. 206). That is, "the intersectional nature of power allows students to position themselves and get positioned by others along multiple axes" (p. 206), a process that still needs to be better understood and documented. Work by Takeuchi (2020) offers an example of a careful multi-level analysis of second language learners in the math classroom and the manner the students are othered in interactions. The study makes evident how "the dynamics between multi-layered identities and learner experiences" (p. 1) are worked out in situ. In contrast, Hand, Penuel and Gutiérrez (2012) applied the notion of framing to study the manner race and power work out in learning environments. Building on these studies, we explore the following research question: What do conscientious moments of interactions reveal about relationality among actors, their histories, positionalities, and potential future selves? In doing so, we attend to the manner implicit assumptions reproduce yet also support transformations of selves in the making, rendering visible the manner learning, identity and power constitute one another. We focus on contentious moments in a girls-only team, as they pursued the construction of a house in which coded electrical circuits ensured that lighting was ecologically sound.

Theoretical grounding

Building on practice theory, we understand learning and identity as a dynamic process, continuously in the making (Holland et al., 1989; Lave & Wenger, 1991). Learning and identity are both jointly accomplished in light of an activity, tools, relationships, but also marked in important ways by the institutional and cultural contexts (Hand & Gresalfi, 2015). While our focus rests on the individuals and the manner learning and identity take shape through interactions over time, we see the contentious moments as also entangled with power which we understand as "co-constructed at multiple scales – historically and structurally at the macrolevel" (partnership between school and CO; institutional politics about language & STEM education), next to interactions and "bodies of individuals" (Philip & Gupta, 2020, p. 197). Through the explorative case study, we aim to bring multiple lenses and layers together to offer deeper insights into the complex power dynamics at play in science education.

Methods

An ethnographic case study was conducted, implying the filming of all meetings in the classroom, supplemented by fieldnotes and a journal. At the end of the school year, we conducted interviews with the teacher and the lead instructor from the ONG, and two years later, with some of the youth who participated.

Activity and Setting. The case is an enrichment activity that was co-animated by a high school science teacher and two instructors from the partner community organization or CO, implying the construction of an ecological house out of cardboard that integrates lights and electrical circuits, created with tools such as an Arduino card and C-code. The project aimed to engage first year high school students with technology in creative and critical ways

(Kafai & Burke, 2014). The one-year project first introduced students to different notions of coding and electrical circuits, and then encouraged them to mobilize these ways of knowing in their own creations of ecological efficient houses. The activity was part of the science curriculum and aligned with the five-year high school science curriculum. That particular high school also follows the five-year Intermediate Program of Education (PEI) associated with the main goals of the International Baccalaureate Program, preparing youth for a future as critical and contributing citizens, concerned with the well-being of humanity and the world, and therefore as committed to lifelong learning, with a particular concern for intercultural relations, globalization, and communication. The International Program now offered in a number of public high schools as an enriched track typically implies entrance exams and ongoing high academic standing, with a fast paced and demanding curriculum and heavy homework load. The school serves an ethnically highly diverse group of students, with the majority of them speaking at least three languages (Native tongue, plus English and French). Given the language charter that resulted in French being the official majority language of Quebec in 1977, all children are schooled in French with the exception of those who are part of the English minority, and to whom the English school system is available.

Data Collection and Analysis. We pursued a video-ethnography of the project, collecting fieldnotes of 17 of the 20 meetings during one academic school year (fall 2017 to spring 2018) and video data of 16 meetings (44 hours total). We then analyzed the work of teams over time, creating video logs and engaging in interaction analysis among our research team (Jordan & Henderson, 1995). In this paper we report on a team of three girls, Maude and Rose (13 years old), who self-identify as French Canadian, and Alexi, who was born in Romania (12 years old), and self-identifies as English Canadian. We pursued timeline interviews of Rose and Alexi in the fall of 2019. Analysis implied the identification of contentious moments of meaning making in the team, over time. We defined those moments as interesting moments, marked by disagreements and contestations of competing interpretations and ways of doing things with the tools provided. From that microgenetic analyses, we turned to the interview data to engage in a multi-layered reading of learning and identity work at play, in the moment, but also as sedimented into enduring identities over time. We made sense of those moments through attention to the manner they seemed entangled with ideologies about girls in science, positionings of second language learners and immigrants, and local meanings that circulate about academic success in a public high school, and effects of SES on academic achievement (Philip & Gupta, 2020). In many ways, our analysis entailed a going forth-and back between the micro interactions among the team and the larger layers of the project and educational structure and reality around it in light of the school system, language requirements and politics associated with them. At the same time, we also carefully attended to the body in action and considered emotions tied to positionings of each other, that transpired in this manner. As noted by Kristensen (2018), analysis can be understood through the metaphor of "peeling an onion" and in the end also implies a bricolage of multiple data sources and analyzed data points. We share a beginning of that bricolage here (Kincheloe & Berry, 2004).

Results

Data Point 1. Alexi caught our attention during the fall, as she worked with Nancy, who like her, had immigrated from Romania. We were struck by how easily and often they engaged in translanguaging, moving among French, English, and Romanian, as they coded and in turn assessed their code as the Led did not light up. The instructor eventually checked everything and noted that it was a problem with the connection and not the code. Note the languages at play as they are trying to figure it out together:

	Talk	Explanation
Alexi :	C'est que confusing, yeah	French & English; (looking at breadboard)
Nancy :	Ça trouve rien	French (examining the code)
Alexi :	C'est blanc depuis tantôt. On voit rien!	French [it's white since a while, we see nothing]
Instructor :	Quais, elle était mal branchée!	French [yes, error was in the connection]
Alexi:	We just have to wait for it to get like below 500	English (they check to see if the range they had chosen in the code was the problem)
Nancy:	Yeah	English
Alexi:	On voit toujours rien!	French (still nothing)
Instructor:	Oui, elle était mal branchée!	French (yes, error was in the connection)

Alexi then called out, "Agh, look, now it's green!" Alexi looked at her code and clapped her hands, calling over to Nancy who fiddled with breadboard "Nancy, we're bosses" and they gave each other a high five. They engaged in an interesting play with languages which seemed to be entangled with felt emotions tied to the project and the people they interacted with. They always switched to French when talking with the instructor, and thereby adhered to the language they had to speak in class by law. At the same time, whenever they looked at the camera and felt its presence, they switched to Romanian, and at one point even commented on that, noting "I wonder what they will do, use google translator?", referring to us, researchers, trying to make sense of their interactions. In the above exchange, Alexi switched to English, aligned with her self-identification as Canadian, and not 'Quebecoise' as the other two girls. English also surfaced naturally, when she was problem-solving (changing the range), when noting it worked, and in reference to themselves as "bosses" and maybe girls who can get the work done. That fluidity among languages is typical of youth like Alexi and Nancy, who grow up as multilinguals in Montreal (Lamarre, 2013). The two girls used their language repertoires to make sense of their coding project, despite local politics that sanction such work and portray French as the language of power within that province. The case makes evident that traditional boundaries among languages and using language as an identity marker just simply no longer hold up (Lamarre, 2013). When local politics do not get in the way, and when youth feel safe to dive into their language repertoires, they do so in ways that further develops their affinity and pride as multilanguage speakers. That contentious moment resulted in the authoring of themselves as "bosses" and embodiment of pride. Yet, the idea of multi-layered identity work and questioning about who actors are and can become in relation to one another took another turn for Alexi later in the school year, as she continued the project as a member of another team.

Data Point 2. Alexi's positioning in that team was quite different and tied up with language politics in other ways. Alexi was 12 years old at the time of the study and had lived in Quebec for 11 years. Alexi talked about her initial integration into the school system during the interview as follows:

> When I came here, I was sent to a private English daycare but they taught us French there already too, as they knew that most of us would have to pursue our education in the French school system. When I started Kindergarten, I was totally bilingual, but I always talked Romanian with my parents, while I talked English with my sister who needed to get better at it and practice it, and then most around me was in English, TV, the news, films, and more. The majority here is English (maybe referring here to Canada), but then there is also the French in Quebec. So if we talk of it globally, it's really English that is the majority and now, I consider myself 100% English, I think in English, I count in English, when I just discuss with somebody, I have to translate my thoughts.

In her new team, we got the impression that Alexi's immigration history and language skills were held against her by her peers, both of whom identified as French Canadian. They positioned Alexi as academically less able and not the kind of person who could become somebody in science or technology, yet did so in subtle ways. That led to many contentious moments of meaning making and identity work, as Alexi was actually an extremely competent coder. There were multiple instances when the others called out for help from the instructor, yet while waiting, Alexi took up the space and rapidly fixed the code. Alexi also continued to switch among French and English, English clearly being the language of power to which she resorted when she asserted her position as somebody who is competent and interested in science and technology. That became evident in a dialogue among the team when they measured the cardboard for their ecological house. It led to an argument about whether they should measure in inches or centimeters. For Alexi it seemed clear from the beginning how the board should be cut, and she intervened multiple times in the conversation, yet her suggestions were brushed aside. She even added in English at one point, "trust me, I'm the math person" which was immediately challenged by Rose, her team mate who came up with a better idea and positioned herself as the "misunderstood Genius." Shocked by that remark, Alexi sat back and then mumbled, again in English, "If anyone of us here is gonna end up being an engineer I think I'm most likely to." Rose tried to tame the argument by adding "do not worry" (in French).

Figure 1. The team struggling with the door they wanted to add to their designed Science Lab

Interview data confirms Alexi's interest in engineering and computing, whereas Rose shared her strong dislike for a career in the sciences. Alexi was not new to robotics or computing as her father is a programmer and taught her much about Java Script. She had fond memories of the coding project, as she thought about it during our interview in 2019, noting "each time we met, we learned something new in programming." She also described her groups' work as ambitious (see Figure 1), "we wanted to create a house with a code to open the door, which in the end never worked as we had just too many wires, and the code, technically it was flawless but in practice, given the wires, it worked one out of five times. I think in the end we managed to make it work." She recalls how stressful the project was given the evaluations their teacher developed, in line with the international school competency requirements. When asked about her future career aspirations, Alexi projected herself as pursuing a career in Aerospace Engineering. She continued, "I want to make spaceships" (in English, before continuing in French), "anything about space always fascinated me." She then passionately talked about events in the history of science that stood out for her, like going to mars, inventing the internet, and now thinking of the future, she shared a sort of science fiction story with us where "we should just ditch the earth and go somewhere else." She was imagining that half of the population should leave the earth, as we have come to its limits. If we would split in half, however, she imagined that "we could keep on living good lives." She continued, "the other half would find a planet that is colonizable, or we could move to Mars and colonize it, I really think this would be one of the best solutions" in light of the current problems tied to climate change and overpopulation on the planet. She continued, "my dream was always to do something really amusing and awesome so that one day, my name would be in a book that students at the University would use and learn with." Alexi was clearly ambitious and invested in some kind of future in STEM with which she strongly identified, in part due to her father's coaching. At the same time, her peers continuously challenged her positioning as a science savvy person. Interestingly, even Alexi's teacher who likes technology, was convinced, after twelve years of experience, that her female students were never too crazy about it. At the same time, the teacher shied away from programming, which in the end may have led to a lack of appreciation on her part of Alexi's skills and ambitions, even though some of them can also be read as problematic.

Conclusion and implication

Alexi's trajectory makes evident how moments of contentious practices, next to stories of participants' learning lives gathered through interviews, can make evident the manner power is worked out and constitutes learning and becoming. It resulted in embodied pathways and ethical trails of engagement that we problematize here as we believe they are consequential for Alexi and at the root of relational histories that continue to undermine equity and social justice in STEM. The study has implications for teacher education and educational practices, both formal and informal, that are committed to educational dignity and justice (Espinoza & Vossoughi, 2014).

The Unexamined Influence: An Object's Perceived Gender on Spatial Reasoning Skills in Girls

Abstract: Explanations for gender differences in spatial visualization and mental rotation typically center on lack of experience or cognitive deficits of females. Our research offers an alternative explanation for these differences–one rooted in the materials used for mental rotation tasks, informed by sociocultural approaches and posthumanist perspectives. Combining a gender sorting task and a mental rotation assessment, this study shows that students–regardless of gender–perceive consistent gender differences of everyday objects. Their ability to mentally rotate each object is related to their gender and the objects' perceived gender. Females perform significantly higher on mental rotation tasks that involve objects that are perceived as feminine, matching scores of males. Yet, the stereotypical mental rotation differences between females and males are seen only on objects perceived as neither feminine nor masculine. The perceived gender of materials included in educational design may shape mental rotation ability.

Introduction

Spatial reasoning skills play an important role in STEM fields (e.g., Uttal et al., 2013). For example, scores on spatial assessments are significant predictors of future attainment of STEM degrees and entering STEM professions (Wai et al., 2009). Yet, these skills are subject to consistent gender disparities favoring males, especially in three-dimensional mental rotation (3DMR; Linn & Petersen, 1985; Voyer et at., 1995). Despite views and societal perceptions that facility with spatial information is an innate talent (e.g., Wai et al., 2009), spatial skills can be taught and improved (Uttal et al., 2013). Women and young girls especially are disproportionately impacted by a lack of opportunities to develop spatial skills due to the stereotype that men are naturally more talented in 3DMR (e.g., Muenks et al., 2020). Rather than considering innate abilities as a source of gender differences in spatial reasoning and, in particular, 3DMR, there seems to be something about who is being invited to engage that may shape students' opportunities to engage in 3DMR practice.

The current study considers the traditionally feminine as its starting point, rather than viewing an increase in girls' engagement with stereotypically masculine activities as the only solution to the 3DMR gender gap. To determine the relationship between gender, material, and mental rotation (MR) performance, we asked: *1) To what extent do students perceive gendered differences of everyday objects and does the gender identity of the respondent affect these outcomes? 2) To what extent does mental rotation of everyday objects vary in relation to students' gender identity and students' perceived gender of objects?* To answer these questions, we first introduced a gender sorting task and asked students (n=89) to sort everyday objects from very feminine to neither feminine nor masculine to very masculine. Then, to test whether students' ability to rotate objects varied by both the gender of the object and the gender of the students, we designed a MR assessment and administered it with another student group (n=51). Findings demonstrate that students perceive gender differences of everyday objects mostly consistently. Additionally, findings showed that MR ability is related to students' gender and objects' perceived gender: female students perform significantly higher on MR tasks that involve objects that are perceived as feminine, matching scores of their male peers. By contrast, stereotypical MR gender differences between females and males were seen in relation to objects that were perceived as neither feminine nor masculine. The results of the study offer an alternative explanation for gender differences and stereotyping in 3DMR tasks that is rooted in materials and not in the cognitive or psychological makeup of females. We argue that the perceived gender of objects included in educational design may shape MR ability.

Background: Mental rotation, gender, and materials

Mental rotation (MR) is an aspect of spatial visualization skills, which describes the ability to understand and imagine an object's spatial relationship to other objects (Linn & Petersen, 1985). These abilities involve the manipulation of visual information, which may include problems of navigation and calculation of shape, size, and fit (Gardner, 1993). MR, in particular, refers to imagining objects at different angles (Linn & Petersen, 1985). Typically considered a cognitive skill, MR is also regarded as a predictor for future career success and engagement with STEM fields (e.g., Humphreys et al., 1993; Wai et al., 2009). Assessments of MR are based on people perceiving two-dimensional images as abstractions of three-dimensional figures through a MR experiment (e.g., French et al., 1963). The Mental Rotation Test (MRT) was designed to measure an individual's MR ability with cube shaped items (Vandenberg & Kuse, 1978).

It was long considered that practice of spatial skills does not lead to long term improvement (e.g., Sims & Mayer, 2002). Thus, findings that boys outperform girls in MR assessments (e.g., Voyer et al., 1995, Linn & Petersen, 1985; Neuburger et al., 2011) can lead to highlight deficits over training effects and possible assessment bias. However, efforts to reduce inequities related to educational and career access have shown that repeatedly mentally rotating objects, including administration of assessments, can lead to improved performance (Uttal et al., 2013). The learnability of spatial visualization skills, especially MR, is hopeful in relation to gender differences and points to inquire to what extent aspects of instruction and gender play a part in MR assessment.

We take a perspective that understands gender as performance (Butler, 1990), we conceptualize gender as a construct that exists beyond humankind, but there are features of tools that send cues to individuals. The strong emphasis on contextual materiality resonates with recent studies that highlight the non-neutral role that a diversity of materials and representations play in producing what can be learned (e.g., Kuby et al., 2017; Peppler, Rowsell, & Keune, 2020). These lines of research suggest that materials and tools are non-neutral and play an active part in shaping domain knowledge (Keune, 2020). The gender associations of tools and material are increasingly important in terms of what people can learn and how people participate. With the present study, we aimed to understand how materials relate to MR ability for female and male students.

Methods

The research was conducted at a Midwestern charter school with two separate cohorts of students (ages 10-18). The gender sorting included 89 students (39 female, 48 male, and 2 gender non-binary) and the MRT assessment included 51 students (15 female, 33 male, and 3 gender non-binary).

The *gender sorting* prompted students to sort everyday objects (e.g., lemon, doll, hammer) based on a mutually exclusive spectrum of five gender categories (i.e., very feminine=5, somewhat feminine=4, neither feminine nor masculine=3, somewhat masculine=2, and very masculine=1). The scale enforced a gender binary also because the prevalent orientation within MR positions females at a deficit. The task had 32 objects, 30 everyday (e.g., dress, box, truck, etc.) and two building block objects from spatial visualization assessments (i.e., MRT and PSVT:R). To probe how students' perception of the objects' gender and students' gender identity related to students' MR scores, we administered a *modified MRT assessment* with the objects from gender sorting, 30 everyday objects and nine MRT items. Based on the original MRT assessment, items of our modified assessment showed the target object above four perspectives of the object, including two mirrored options and two correct rotations (Figure 1). To answer an item correctly, students had to select both correct rotations.

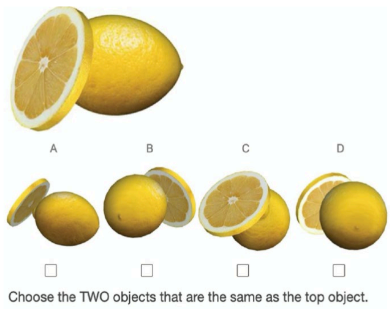

Figure 1. Modified MRT assessment item with everyday object.

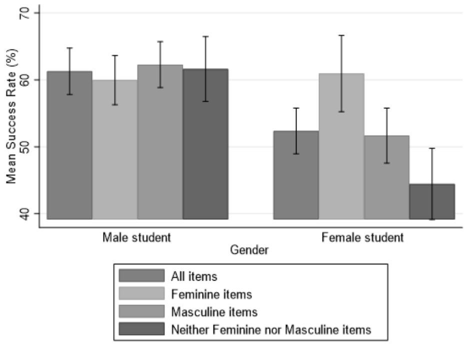
Data analysis

Using a two-sample t-test, we divided the participants in two groups based on their gender to test whether gender sorting was independent of students' gender for any of the 32 objects. For each object, if the mean sorting score by female students was different to that by male students, we rejected the null hypothesis of equal means between genders. A p-value of the two-sample t-test lower than 0.00156 (i.e., the Bonferroni-adjusted p-value of 0.05/32) meant that gender sorting varied based on student gender.

The success rate score for the MR assessments was represented with *four* variables (i.e., all, feminine, masculine, and neither feminine nor masculine items). We compared *different* success rates to test whether MR varied in relation to students' gender and students' perceived gender of objects. Specifically, we calculated Cohen's d and Hedges's g estimates to test the null hypothesis that the mean success rate score of male students was equal to the mean success rate score of female students. If we reject the null hypothesis, Cohen's d and Hedges's g estimates show the difference of means in terms of the pooled standard deviation of both gender groups. The expected effect size is between 0.40 and 0.75 (see Uttal et al., 2009 for a review).

Results

Taking all three conditions together, students performed a total of n=85-87 sortings per object on a scale from 1 (very masculine) to 5 (very feminine). Students sorted 16 objects as more feminine, 4 objects as neither feminine nor masculine, and 12 objects as more masculine. Overall, a two-sample t-test showed that none of the everyday objects was sorted differently in relation to the students' gender identity (i.e., p-value > 0.00156).



Note: the error bars represent the standard errors of each mean success rate score.
Figure 2. Mental rotation scores related to gender identity of respondents and perceived gender of assessment items.

Across all items, female students' MRT scores were lower than those of their male peers (see Figure 2). Where male students rotated on average 61.28% of items correctly, female students rotated 52.36% of items correctly. However, the difference between the average male and average female student scores was not statistically significant (p-value 0.12). Across all items, female students performed best on items with feminine objects. By contrast, male students performed best on items with masculine objects and worst on feminine objects. Nevertheless, the average score of female and male students for feminine objects was not statistically different (p-value 0.88). On feminine items, female students performed only slightly above their male peers on average. When objects are considered feminine, gender differences in MR scores disappear.

Most interestingly, female students' MR scores were significantly negatively affected when objects were neither feminine nor masculine (p-value 0.038). On average, on neither feminine nor masculine items, male students scored 61.62% correctly and female students only 44.44%. Male students outperformed female students between 65% and 67% of a pooled standard deviation for the mean success rate score of neither feminine nor masculine items (Table 1, column 4). While the absence of a control group may overestimate the effect size, this large effect is within the range that other studies with similar designs found (Uttal et al., 2013).

Overall, the effect size analysis presented that for objects that were sorted as neither feminine nor masculine, the overall gender difference in MR scores was consistent with the results typically found in MR assessments (Voyer et al., 2006). These results suggest that objects that seem gender neutral favor male students in MR assessment, reproducing gender differences.

Table 1: The effect size of MR scores comparing male and female students.

	All items	Feminine items	Masculine items	Neither feminine nor masculine items
Cohen's d	0.49	-0.05	0.57^{+}	0.67^{*}
Hedges's g	0.48	-0.05	0.56^{+}	0.65^{*}

Note: Bootstrap standard errors with 1000 repetitions: + p<0.10, * p<0.05, ** p<0.01, *** p<0.001

Discussion and implications

When asking students to sort everyday objects across students' perceived societal gender stereotypes, female and male students sorted the objects predominantly similarly across all object conditions. Regardless of gender identity, students categorized the gender of everyday objects consistently. The results suggest that students' gender identity did not largely affect students' perception of the genderedness of objects. These results further suggest that gender associations may be inherent to educational assessments and could risk introducing a bias.

The findings demonstrate that objects that students consider as neither masculine nor feminine can explain differences in MR scores related to student gender. Gender perception of objects seems to matter for how well a rotation task is performed. The results contribute to a possible explanation that gender differences are related to power and positionality of gendered objects rather than cognitive makeup. For example, where male students may consider masculine objects for them and, therefore, possible to rotate, female students may disassociate with these objects. The differences in students' scores are important because assessment designs may be based on false assumptions that gender neutral items eliminate gender-related assessment bias.

We see potential for considering everyday objects for the design of MR assessments. Especially feminine items seem promising for reducing possible gender differences in MR. This study considered gender on a binary scale, which reduces the wide spectrum of possible gender identities and gender perceptions. Thus, we consider it as important that future studies are conducted with a larger sample size of gender non-binary students and to consider ways to break out of gender binaries in the gender sorting and assessment results.

Concepts and Conceptual Practices in Teaching: Identifying Teachers' Functional Concerns in Inquiry-Based Mathematics Intervention Courses

Lara Jasien, CPM Educational Program, larajasien@cpm.org

Abstract: This paper contributes empirical evidence for an understudied, rudimentary question of what teaching is *for teachers* by identifying the *functional concerns* (FCs) that arise for teachers during instruction. Using grounded theory's constant comparative method, video records of six teachers' enactments of two lessons in an inquiry-based mathematics intervention course were content logged and analyzed with thematic, descriptive narrative memos. These were then coded to emergently identify teachers' *conceptual practices* (CPs). Analysis of relationships between CPs illuminated four overarching FCs. Tellingly, the CP of building on student thinking was the only CP teachers enacted towards all four FCs. Better understanding what it means and what is needed to teach for inquiry in intervention courses can challenge back-to-basics approaches that cut off students' opportunities for meaningful learning.

Teachers make decisions every day that are consequential for students' learning. These decisions are big and small, conscious and unconscious. To support teachers in making decisions, researchers have developed tools for professional development (PD) and teacher education. For example, the Teaching for Robust Understanding (TRU) framework helps teachers reflect about dimensions of classroom activities that might serve as levers for change, helping them develop intentionality in decision-making (Schoenfeld, 2019) as a way to foster equity. Other resources for teachers' decision-making are action-based, such as Smith and Stein's (2008) description of 5 Practices for orchestrating whole class mathematical discussions. Both tools are most helpful for instructional decisions made in the planning stages of instruction. In-the-moment decisions are more difficult to influence (Pfister et al., 2015). Likely because frameworks like TRU and the 5 Practices provide *aspirational* visions of mathematics instruction that focus on ideal models, their descriptions do not quite capture the complexity of decision-making in teaching mathematics.

Currently, our theories of and designs for teacher learning are based more on aspirational, ideal types than on nuanced, evidence-based understandings of what teachers do, what motivates them, and how they learn (Kennedy, 2016). Thus, it is no surprise that teachers struggle to shift their practices, especially in courses that target students who have not been adequately supported in prior mathematics classes who also may not easily fit in the templates that aspirational frameworks offer. Teachers in all courses, but especially intervention courses, may struggle with teaching that aligns with reform frameworks, since few resources account for teachers' lived instructional experiences. Resources commonly provided to intervention teachers include rote curricula and recommendations to forego reform practices. This is likely partially due to the paucity of mathematics education research on students in intervention courses (Lambert & Tan, 2020). In addition, teachers can fall back on deficit perspectives and rote methods when they feel like students are struggling or like there is a mismatch between the difficulty of the mathematics problem and their students' current ability (Jackson et al., 2017; Horn, 2007).

Here, I develop a grounded framework of inquiry-based teaching in mathematics intervention classrooms by beginning with primary evidence of instruction in understudied classrooms — intervention classrooms. My research question is, *What is the main work of teaching, from a teacher's perspective, in an inquiry-based classroom for students who have academically struggled?* I articulate an evidence-based account of teachers' functional concerns.

Conceptual framework

Recently, teachers' decision-making has been described through a tripartite model of pedagogical judgement (Horn, 2020), including dimensions of pedagogical action, pedagogical reasoning, and pedagogical responsibility. *Pedagogical action* describes the choices teachers make, whether intentional or not. *Pedagogical reasoning* is the logic behind these actions—the same action may be done for many different reasons. *Pedagogical responsibility* involves teachers' sense of obligations to ethical principles or to situational constraints such as mandates from administration. Together, these constitute the pedagogical judgement that informs teachers' decision-making.

Teachers' *functional concerns* involve a practical sense of pedagogical responsibility. Functional concerns are pragmatic in that they focus on elements of instruction that are within teachers' control. For example, teachers might feel an obligation to support learners' retention and transfer of content, but they focus their attention—their concern—*in-the-moment* of teaching on creating coherent and relevant mathematics experiences.

In this way, learners' retention and transfer may be *goals* that emerge from teachers' sense of pedagogical responsibility, as distinguished from the phenomenon of interest here: teachers' *concerns*.

Scholars seek to shape teachers' concerns in practical ways. For example, the TRU framework helps teachers reflect on five dimensions of classroom practice that Schoenfeld (2019) describes as "necessary and sufficient to characterize powerful learning environments" (p. 3): cognitive demand; equitable access to content; agency, ownership, and identity; and formative assessment. While these five dimensions seem to characterize powerful learning environments, they do not explicate a theory of teacher learning that is grounded in teachers' daily work.

Theoretical framework

Pedagogical judgement can be identified in pedagogical activities (i.e., actions and the *meaning* behind them). Pedagogical activities constitute *conceptual practices* — "recurring patterns of purposeful activity that are distributed over people and technologies" (Hall & Horn, 2012, p. 241) in particular practices. I examine teachers' *enactment* of curriculum, with the curriculum functioning as a formal representational infrastructure (i.e., the technologies, ways of talking, and materials that support how people engage; Hall & Horn, 2012), in order to learn what concerns anchor teachers' decision-making. Instead of highly structuring teachers' concerns and conceptual practices, the representational infrastructure of the curriculum is a setting with constraints and affordances that teachers move through to address their functional concerns. Constellations of conceptual practices make up functional concerns.

Research design

The representational infrastructure for these six teachers was an inquiry-based intervention curriculum that foregrounded student exploration and sensemaking. The course was ungraded and emphasized big ideas in algebra, leveraging tools such as Desmos to support student collaboration on complex mathematical ideas.

Data collection

Data collection aimed to capture teachers' talk, gestures, and movement through the classroom. Data include Swivl (i.e., teacher tracking) video-records of observations of six teachers from different locations across the United States teaching the same two lessons, which were part of a larger year-long curriculum. Each lesson was followed by a video-recorded debrief with a curriculum coach. These debriefs focused on teachers reflecting on how the lesson went, with coaches acting as thought-partners rather than advisors.

Data analysis

To understand the work of teaching from teachers' perspectives, I used grounded theory's constant-comparative methods (Corbin & Strauss, 2014) and made close-to-data inferences about teachers' functional concerns in inquiry-based mathematics intervention classrooms by looking at what was *stable* and *variant* across six teachers' enactments of and reflections on two of the same lessons.

Phase 1: In the first round of analysis, I created time-indexed content logs (Derry et al., 2010) for classroom videos and teacher debriefs with their coaches. Then, I looked for recurring teacher actions and the outcomes of these actions that seemed to satisfy teachers (allowing me to infer meaning behind the actions), noting for example, the ways in which teachers organized and set norms for participation structures, cared for relationships between themselves and students and between students, and held themselves and students accountable for pacing. Phase 2: From the content logs of both debriefs and classroom videos, I generated descriptive, narrative memos (e.g., Cobb & Whitenack,1996; Powell et al., 2003) organized by themes for each lesson for each teacher. These themes (such as *emphasis on individual students' math history* and *modeling curiosity*) were not determined a priori, but rather were emergent from and closely tied to what became salient as I parsed each teacher's lessons and debriefs. Sometimes this process required going back to the video record to clarify or gain more nuance on a teacher's instruction. Phase 3: After identifying themes in each lesson for each teacher, the themes were compared and collapsed across into broad descriptive categories (Corbin & Strauss, 1990). These are *the conceptual practices of teaching* in this data. Phase 4: To better understand their dimensions and the boundaries between them, I examined the narrative memo coded under each theme for each conceptual practice and selected examples illustrating more and less productive realizations of the conceptual practice. I operationalized *productiveness* by determining whether the realizations elicited student sensemaking in classroom videos as described in the narrative memo. This process of defining each conceptual practice and selecting a spectrum of examples of each one in action uncovered how conceptual practices were both unique and related. This examination of the distinctness of each conceptual practice resulted in four clusters of conceptual practices, with each cluster representing a functional concern in teaching inquiry-based mathematics to learners with a history of academic struggle.

Conceptual Practices: In my constant comparative analysis of six teachers teaching the same two lessons at different points in the year, I identified 15 pedagogical activities that I theorize as conceptual practices of teaching inquiry-based mathematics to students who have previously struggled. These 15 conceptual practices (codes) represent the daily work of teaching; they are inferred meanings of what teachers do and say (activities, not actions). These conceptual practices are distinct in that they serve different purposes for each teacher (see list A-D in the Findings). Due to space limitations, the definitions are not included in this manuscript; the names of each conceptual practice meaningfully describe what they represent. While distinct, these conceptual practices are also related to each other, clustering together to support four functional concerns in teaching inquiry-based mathematics to students who have struggled.

Findings

The main work of teaching from a teacher's perspective in an inquiry-based classroom for students who have struggled involves 15 conceptual practices that cluster together to constitute four functional concerns in-the-moments of teaching.

Concepts and Concerns: The conceptual practices, or pedagogical activities of teaching, are thematically related and constitute functional concerns in teaching (concepts A-D below). They represent the job of teachers—their concerns or responsibilities—from teachers' perspectives.

A. **Mathematical Correctness & Completeness** (concept): *How can I make sure that student work is accurate, thorough, and finished?* (concern). Conceptual Practices: (1) Seeking final answers on a task or sub-task, (2) Navigating student uncertainty, (3) Assessing student progress, (4) Redirecting students' mathematical thinking, (5) Building on students' mathematical thinking
B. **Mathematical Coherence & Relevance** (concept): *How can I make sure that mathematics is meaningfully connected to students' prior knowledge and lives?* (concern). Conceptual Practices: (6) Generalizing mathematical strategies, (7) Connecting mathematics, (8) Connecting mathematics to everyday life, (9) Offering mathematical choices
C. **Student Motivation** (concept): *How can I make sure that students are interested enough to get started and to persevere through uncertainty and confusion?* (concern). Conceptual Practices: (10) Offering non-mathematical choices, (11) Attending to student confidence (high inference), (12) Caring for relationships (high inference)
D. **Student Access** (concept): *How can I make sure that students can get started on the task and that struggle stays productive?* (concern). Conceptual Practices: (13) Unpacking the task, (14) Setting participation norms, (15) Organizing materials and student bodies

These functional concerns are all mathematics teaching specific, but also differently emphasize concerns about mathematics or students. Figure 1 illustrates how conceptual practices work towards constituting multiple concepts, including overlap between more strongly mathematics- or student-centered concepts. In the list above, the conceptual practices are located under the concept they most heavily constituted in the data.

Notably, *Building on student thinking* is the only conceptual practice that contributed to all four concepts. "Building on student thinking" happens when teachers elicit student ideas as a primary way to support student learning, particularly by eliciting some students' ideas publicly. Positive instances of building on student thinking include asking students to share their thinking with the teacher or with each other and then pressing for connections or *why* explanations. A less desirable instance of building on student thinking is, for example, referencing student ideas while explaining complex mathematical concepts before allowing exploration. Because *Building on student thinking* contributed to all four concepts, professional learning around this conceptual practice could be a powerful way to support shifts in instruction.

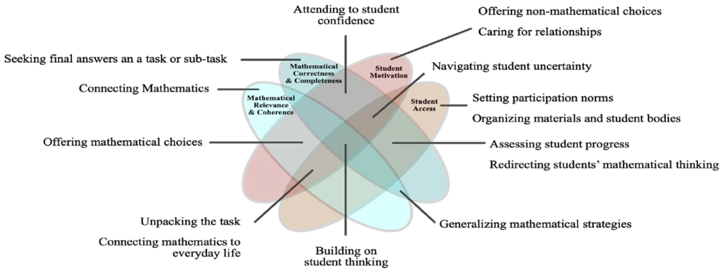

Figure 1. Relationship between concepts in terms of conceptual practices.

Implications

This paper contributes empirical evidence for an understudied, rudimentary question of what teaching is *for teachers* (Cohen, 2011) in reform-oriented intervention courses by identifying teachers enacted functional concerns. Too often, teachers experience PD as disconnected from teaching. PD around functional concerns may aid in supporting teachers to develop a practice of intentionality around instructional decisions that are often tacit, routine, and unconscious. For example, it may support teachers to develop a *professionalizing discourse* (Horn & Kane, 2019) in which they collectively work to develop shared meanings of concepts by pressing each other to explicitly connect, with detail, the particular contexts of their daily work with the functional concerns of teaching. This discourse centers teachers' meanings and concerns, making it more likely that PD fostering such discourse will make contact with what teachers actually do and care about, and, ultimately, influence classroom practice.

Chen, and Nadav Ehrenfeld from the Teacher Learning Lab at Vanderbilt for their support and guidance in refining this analysis' contribution, and to Mark Ray and Dr. Lisa Amick (CPM) for their support during all phases of the project, from research design to data collection and analysis to the drafting of this manuscript.

Supporting Third Graders' Use of Subroutines in Programming through Play Versus Worked Examples

Sezai Kocabas, Purdue University, SKocabas@purdue.edu
Laura Bofferding, Purdue University, LBofferd@purdue.edu

Abstract: We conducted an in-depth analysis to better understand the role of playing versus analyzing worked examples when learning programming commands. Our findings, focused on two pairs of third graders, demonstrated that students did not use complex programming commands when only playing; whereas, when supported through analysis of worked examples, they did use subroutines. Both pairs started to identify repeating patterns in their code once they had a worked example where a subroutine was used to repeat a set of commands. Yet, having time to play before analyzing worked examples in programming contexts may provide subtle benefits, especially for more abstract commands such as subroutines. Unlike prior studies, our findings suggest that looping concepts can be taught within the concept of subroutines, even with young students.

Tangible programming devices are popular for introducing younger students how to program because students can see the direct results of the commands they program (e.g., Horn & Jacob, 2007). Depending on the type of device, students might program a robot (or other object) to make noises, light up, turn, and move forward or backward (e.g., Sullivan & Bers, 2016); all of these actions are easy to hear or see. However, some elements of programming, such as conditionals, loops, and subroutines, are still abstract in tangible forms because some of the steps or logic are not heard or seen in the same way. For example, Sullivan and Bers (2016) explored pre-kindergarten through second grade students' learning of programming involving KIBO robotic kits combined with a CHERP tangible programming language. At the end of the eight-week robotics curriculum, students struggled more with loop and conditional tasks than sequencing tasks.

There are several ways to help young students make sense of programming commands. One option, based on a constructionist philosophy, is to let students play and explore with the device, providing them with the opportunity to question and discover on their own (Monga et al., 2018). In a study where first and third graders played versus explained their program and goals while playing a tangible programming game, just playing the game supported students' (particularly females') improvement the most (Bofferding et al., 2020). On the other end of the spectrum, students could receive explicit instruction on commands and how to use them and then have targeted practice using the concepts. However, Lee et al. (2013) explored kindergarten students' social interactions through unstructured and structured programming curricula and did not find an impact of instruction on robotic skills and programming concepts. In the middle of the spectrum, students could use worked examples to reason about how a particular command works. In one case, worked-examples supported nine- to ten- year-old students' learning to program. (Joentausta & Hellas, 2018). To better understand such practices, we used an in-depth analysis of two pairs of third graders, unpacking their understanding of subroutines and programs depending on whether they engaged in playing or analyzing worked examples.

Play versus worked examples

If students have sufficient domain knowledge, play might be at least as good or even better than using worked examples (Tuovinen & Sweller, 1999). Playing that involves no explicit instruction would be helpful to learn programming (McCoy-Parker et al., 2017; Mitamura et al., 2012; Monga et al., 2018) by reducing extraneous cognitive load (Hawlitschek & Joeckel, 2017). However the benefits of play might differ based on the context; playing was more effective on first and fifth graders' creative scores on robot programming but less effective on their technical scores than explicit instruction (McCoy-Parker et al., 2017).

On the other hand, worked examples are guided instruction techniques which provide students with step-by-step problem-solving instructions used to teach problem-solving processes (Atkinson et al., 2000) and can help students focus on understanding, reasoning, and encoding (Ward & Sweller, 1990); they are appropriate to guide students to solutions for difficult problems (Pirolli & Anderson 1985) so that students do not waste time on unhelpful strategies. However, the design of worked examples is important (Sweller et al., 1998). Examples with errors (i.e., incorrect worked examples) support students to use more self-explanations when interpreting the concept, identifying errors, and correcting bugs (Zhi et al., 2018). Zhi and colleagues (2018) found that analyzing incorrect examples can effectively support older students' learning about loops; however, analyzing a mixture of correct and incorrect worked examples can be helpful for students who have sufficient prior knowledge (Große & Renkl, 2007).

Current study

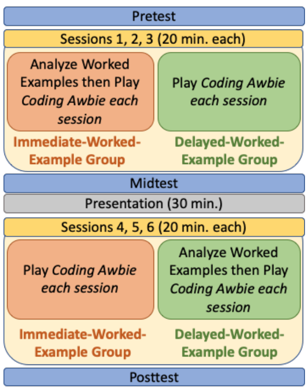
In this study, we used play and worked examples to help third graders understand and reason about programming commands, with an emphasis on abstract concepts related to subroutines and loops. Although worked examples can help middle school students learn more abstract programming commands (e.g., Zhi et al., 2018) and play can help younger students learn more concrete programming commands (e.g., Mitamura et al., 2012), our aim in this study was to identify the relative benefits of both methods for third grade students and determine when either method is most helpful. Therefore, a further aim was to gain clarity on whether analyzing worked examples was more beneficial during their initial exposure to programming or after given some time to play as we explored two research questions: How do students, depending on their prior experience playing the tangible programming game, interpret the worked examples and the meaning of the subroutine programming block? How do they use information from the worked examples in their pair and their own programming?

Methods

Setting, participants, study design, and materials

This study took place at a school in a midwestern district of the United States where approximately 45% of students qualified for free or reduced-price lunch. To elevate the voices of females in early programming, we selected two female pairs of third graders for this in-depth analysis (out of 26 students). We chose the two pairs from the same classroom and who both attempted to use the subroutine block the most in their sessions. Students Sheep7 and Sheep8 played during sessions 1-3 and analyzed worked examples in sessions 4-6. Students Sheep5 and Sheep6 analyzed worked examples in sessions 1-3 and played in sessions 4-6.

To examine the role of worked examples versus play, we employed a repeated-measures, between-groups design (see Figure 1). For this paper, we report on students' descriptions of the subroutine programming block as well as on their programs to move Awbie to a specific spot (on the posttest, they wrote a second version of their program using the subroutine block). Additionally, we report on an item where students explained a program involving grab and walk blocks repeated within a subroutine. Between the pretest and midtest, students worked in pairs to either play the programming game or analyze worked examples plus play, and students switched activity-foci between the midtest and posttest.



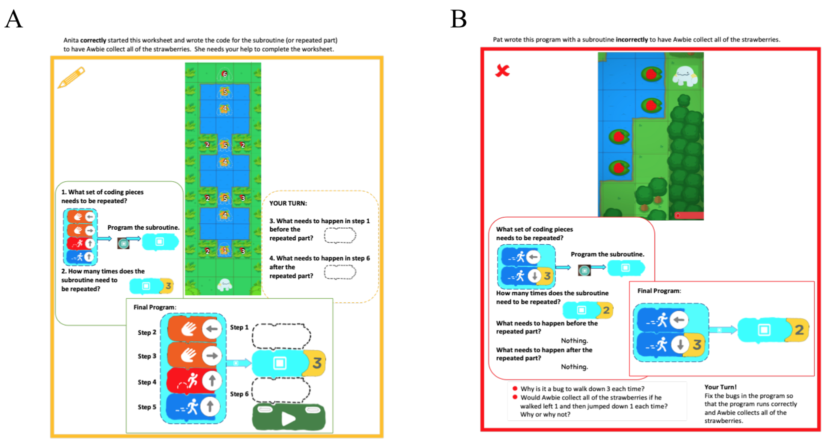


Figure 1. Study design.

Figure 2. Example (A) incomplete and (B) incorrect worked examples.

In the worked example sessions, students spent the first 5-8 minutes analyzing and answering questions about worked examples. In session 2 (or 5), students analyzed a correct, worked example to show how to use a subroutine block to repeat a set of grab and walk movements. Then they had to identify missing problem blocks in an incomplete worked example (see Figure 2A), and they found and fixed an error with a subroutine (see Figure 2B). In session 3 (or 6), students analyzed a correct worked example about using a warning block within a subroutine, and they fixed a worked example that incorrectly repeated a jump within a subroutine.

Analysis

Across subroutine items, we identified shifts in students' explanations (focusing on accuracy and conceptual understanding) and differences between the two pairs (i.e., the subroutine block can be programmed to do a set of commands or the subroutine can be repeated by adding numbers to the subroutine block or by making a subroutine of the subroutine). In order to characterize how pairs used the information from the worked examples, we identified the extent to which the pairs implemented subroutine ideas (and their effectiveness in doing so) within the sessions. Finally, at the individual level, we performed a similar analysis to the sessions using a programming item from the pretest, midtest, and posttest.

Findings

Overall, students showed a better understanding of subroutines after analyzing worked examples (see Table 1).

Table 1: Students interpretations and use of the subroutine on pretest, midtest, and posttest

Group:	**Pretest**	**Midtest**	**Posttest**
Intervention		**Explaining the Function of the Subroutine**	
-First	-------	Repeating (Sheep5, Sheep6)	Repeating (Sheep5, Sheep6)
-Second	Related to repeating (Sheep7)	-------	Can be programmed, involves repeating (Sheep7, Sheep8)
Intervention		**Programming the Character, Awbie**	
-First	-------	Correct (Sheep5, Sheep6)	Correct, recognized repeating pattern but did not program subroutine block (Sheep5, Sheep6)
-Second	Correct, not efficient (Sheep7); Debug (Sheep8)	Correct (Sheep7, Sheep8)	Correct, programmed subroutine with full program, did not have it repeat (Sheep7, Sheep8)

During sessions one to three, when analyzing the worked examples, Sheep5 and Sheep6 explained that the subroutine could repeat programmed commands by adding number blocks to the block; however, they did not explain that the subroutine block can be programmed to do a set of commands. They did not find the correct commands to complete the program in Figure 2A; but they were able to explain the problem with the program in Figure 2B. When they tried to fix an incorrect worked example that repeated a jump too many times within a subroutine. They explained the subroutine and fixed the bugs, although they created a new program that did not involve a subroutine. When playing, although the intervention-second group did not recognize repeating patterns, the intervention-first group started to recognize repeating patterns after analysis of the worked examples (which emphasized repeating patterns in the code). However, rather than programming the subroutine block with the part to repeat (*"walk right 1, walk down 1"*) and putting a number on the subroutine button, they placed the blocks to repeat after the subroutine button in the sequence of code. Sometimes they tried to use the subroutine button but forgot to program it first.

During sessions four to six, when analyzing the worked examples, Sheep7 and Sheep8 now explained that the subroutine could repeat programmed commands by adding number blocks to the block, and they mentioned they could repeat the programmed commands by using number blocks on the subroutine. Due to an implementation error, Sheep5 and Sheep6 reanalyzed one set of worked examples and, this time, identified the missing commands in Figure 2A, while Sheep7 and Sheep8 correctly identified the first missing command. They also fixed the subroutine with too many jumps by changing the code and not using the subroutine to do the new repeated part. When playing, both groups recognized repeating patterns and tried to use the subroutine block, but both groups forgot to program the subroutine block; instead, they put it at the end of the part they wanted to repeat. The intervention-second group eventually remembered to program the subroutine block and used it to *repeat jump right 1* three times, and they even put additional code after the block. By session six, they also used the subroutine to repeat by making a subroutine of the subroutine!

Discussion

Although this analysis focuses on two pairs of students, a limitation of this analysis, the results follow larger trends from our research for those students who used the subroutine in their programming. Using the worked examples was beneficial for helping students understand and use the subroutine block. Sheep5 and Sheep6 were better equipped to try using the subroutine block in their second and third sessions because they engaged with worked examples involving the subroutine block; whereas, Sheep7 and Sheep8 did not try using the subroutine block until they had their first worked example involving the subroutine block. This is particularly interesting because both pairs had been exposed to examples on the pretest and midtest that required them to interpret the action of the subroutine block; however, they only tried to use the block when they had a worked example with one. Although prior research suggested that students would have difficulty learning abstract programming concepts (Sullivan & Bers, 2016; Zhi et al., 2018), our results suggest that students might be less likely to learn these more complex programming commands through play only; they can learn more abstract programming concepts with the support of varied worked examples (Lee et al., 2013).

Based on this study, students who initially played made just as many gains as students who started with worked examples, and arguably, their use of the subroutine button was more complex than the students who started out with worked examples. Therefore, having some time to play before analyzing worked examples in programming contexts may serve some subtle benefits, especially for more abstract commands, an area that should be explored further. Lastly, unlike the previous studies that were teaching loops (Sullivan & Bers, 2016; Zhi et al., 2018), we taught the repeating idea within the concept of the subroutine. Our study showed that students developed an understanding about programming a set of commands and calling them back *while* developing reasoning about repeating a set of commands at the same time.

Multimodal Generalizing in a Mathematical Videogame

Caro Williams-Pierce, University of Maryland, carowp@umd.edu

Abstract: This study adapts and augments Ellis and colleagues' Relating, Forming, and Extending generalization framework by examining how multimodal generalizing emerges from a player's interaction with a mathematical videogame. We review the literature on generalizing, describe how embodied cognition (particularly physical gesture and digital actions) contribute to the field's understanding of generalizing, and describe the videogame. We then detail our multimodal evidence of generalizing during gameplay, and conclude that attending to physical gesture and digital action are a necessary component of examining multimodal generalizing.

Introduction

The bulk of research investigating students' mathematical generalizations has occurred in the domains of early algebra and algebra, and has relied heavily on patterning tasks (e.g., Rivera, 2010). Doerfler (2008) has noted, however, that the presentation of patterning tasks can have a strong regulating or even restrictive effect on students' generalizing. These tasks may provide figural cues and expected progressions that encourage a narrowly prescribed range of potential generalizations. In contrast, he argued for *'free'* generalization tasks that are not restricted by pre-given purposes and there is a need to better understand how students construct generalizations in more open-ended tasks or contexts, such as occurs during mathematical play (Williams-Pierce & Thevenow-Harrison, accepted). Simultaneously, we focus on investigating how generalizing itself may transform during novel and multimodal contexts. We do so by leveraging established research in embodied cognition, which recognizes evidence of mathematical learning contained in modalities other than speech (e.g., Williams-Pierce et al., 2017). In particular, we adapt and extend Ellis and colleagues' generalization taxonomy (Ellis, Tillema, Lockwood, & Moore, 2017; Ellis, Lockwood, Tillema, & Moore, under review) to the context of a mathematical video game designed to provoke mathematical play (Williams-Pierce, 2017a). Our research question was *How does generalizing emerge from playing a mathematical videogame?* Here, we share two different results: first, we contrast how *recursive embedding* (Lockwood & Reed, 2016; Ellis et al., 2017) appears in a different form in gameplay; and second, we examine how multimodal generalizing occurs by extending the data sources used to infer generalizing from primarily spoken language and written work to physical and digital gestures. We introduce generalizing and embodied cognition, our game and methods, give an illustrative example of how multimodal generalizing manifested in gameplay, then conclude with implications.

Theoretical frameworks: Generalizing and embodied cognition

We use the Relating, Forming, Extending (RFE) framework (Ellis et al., 2017; Ellis et al., under review), which draws on the multiple types of generalizing accounted for by Ellis' generalization taxonomy (2007a; 2007b). The RFE framework is built upon the results from 146 interviews with 93 participants in middle school through college in the domains of algebra, advanced algebra, trigonometry/pre-calculus, and combinatorics. These interviews incorporated a wide variety of problem types, including open-ended and complex problems that could afford a number of different viable generalizations, therefore responding to Doerfler's (2008) call to leverage more "free" generalization tasks unrestricted by pre-determined goals. Due to space restrictions, we describe solely the components of the RFE framework that appear in the Findings section, which is primarily Forming, with some Relating and Extending. Forming is the development of an initial, sometimes tentative generalization, and can encompass a number of different actions. *Isolating constancy* often occurs as a precursor to *identifying a regularity*, which can either be *extracted* (identifying a common feature across multiple observed cases) or *anticipated* (predicting that a feature will continue to future cases, even if this has not been observed). Students can also form generalizations through non-searching actions, such as *associating objects* (forming a relation of similarity between two or more mathematical objects), or by *establishing a way of operating* by forming novel mental operations that become the foundation for a generalization that can be applied to a broader domain. Once formed, extending is the use of a generalization, sometimes to a broader domain. When *continuing* a generalization, one does not alter it, but when *operating*, the student will alter the expression of the generalization in order to extend it to a new case. *Transforming* a generalization involves changing the generalization itself. The one part of relating that was particularly evident in our data was *recursive embedding*, which is the act of reflecting on prior activity and inserting that activity into one part of a new situation (see also Lockwood & Reed, 2016).

However, the RFE framework has relied primarily upon spoken and written language as evidence of generalizing, so we now introduce aspects of embodied cognition as a way to understand other types of evidence.

Gestures are a recently identified key component of mathematical communication and cognition (e.g., Alibali & Nathan, 2012; Williams-Pierce et al., 2017). The ways in which physical gesture accompanies spoken language in order to contribute unique information about mathematical reasoning is well-documented (e.g., Alibali & Nathan, 2012; Williams-Pierce et al., 2017). Alibali, Boncoddo, and Hostetter (2014) described gestures as "movements of the hands and body that are integrally connected with thinking, and often, with speaking" (p. 150). In particular, Hostetter & Alibali (2008) note that "The isomorphism between images and gestures is manifested in their frequent co-occurrence. Gestures often occur when speakers express information that evokes images" (p. 501). Consequently, embodied cognition – particularly gesture as simulated (digital) action – needs to be considered when examining multimodal generalizing, particularly with Doerfler's (2008) "free" generalization tasks that do not attempt to *a priori* constrain generalizing.

Context and methods

Rolly's Adventure (*RA*) represents multiplicative reasoning (Hackenberg, 2010) through quantities (e.g., Thompson, 1993), where players engage in cycles of mathematical hypotheses (Williams-Pierce & Thevenow-Harrison, accepted) about the underlying and implicit mathematical relationships within the game (Williams-Pierce, 2017a, 2017b). The artefacts and interactions are based solely upon the game and the participants' physical gestures - no other tools were provided or allowed. Participants directed their digital avatar to interact with the game, and regularly used physical gestures to supplement their spoken language. The goal of each puzzle in the game is to fill a digital hole with iterated and/or partitioned copies of a block, and the overall trajectory was designed to support generalizing across the puzzles as each puzzle becomes more difficult. In other words, players were introduced to new problematic situations that created new disequilibrium, causing the need to engage in continued generalizing to regain equilibrium. This approach, combined with the non-standard representations and interactions presented by *RA*, led to players perceiving and engaging the game as a "free" generalizing task, despite the designer's initial goal of evoking learning about multiplication of fractions. For more information about *RA*, see Williams-Pierce (2017a, 2017b) and Williams-Pierce & Thevenow-Harrison (accepted).

The data analyzed for this paper comes solely from the *RA* gameplay of one middle-school aged participant, Ike. Since *RA* is a console game, Ike sat about 10 feet from the television and held a controller. A video camera was positioned to capture their bodies and audio, and Roxio screen-capture software was used to capture their gameplay. During gameplay, the interviewer sought solely to understand Ike's thinking, and did not direct their learning through questions or evaluation, which allowed Ike to engage with the game as a "free" generalization task, rather than an activity with a single correct answer. After data collection, the video record of the participant's body and the screen capture of the gameplay were synced and transcribed to include spoken language, gestures, digital actions, and key gameplay points. We used MaxQDA, software for qualitative data analysis, to implement a mixture of emergent and *a priori* coding (Williams-Pierce, 2017b, Williams-Pierce, 2017a; Williams-Pierce & Thevenow-Harrison, accepted). Our holistic focus here is on multimodal generalizations, based upon the *a priori* RFE framework infused with embodied cognition.

Findings

Since *RA* has no explicit instructions, Ike begins play by activating various buttons and attending to the feedback and failure mechanisms. First, they activate the 1-button, and fail; then activate the 3-button, and fail; then they activate the only remaining button, the 2-button, and are successful. Although there is insufficient evidence of generalizing during this interaction, later patterns of engagement provide evidence that the establishment of a *regularity* occurs here. In other words, they learned in this puzzle that moving up the row of buttons causes a larger quantity of resulting blocks, whereas moving down the row of buttons results in a smaller quantity of blocks. Ike's uncovering of this (fairly trivial, but crucial) mathematical pattern in RA provides the foundation for their recursive embedding in future puzzles. As Ike continues playing RA, they quickly determine that filling the hole is the goal, and that there is some type of relationship - as yet unknown - between the buttons, the initial amount in the hole, and the resulting amount deposited. In other words, Ike engages in *continuing* and then *operating* on the *regularity* they noticed earlier: if they activate a button and the amount deposited in the hole is too little (or too much), then they need to move up (or down) a button. They then recursively embed this activity, as they have recognized that enacting the same digital actions in every new puzzle will lead to more information about the deeper, less trivial mathematical patterns within the game. Although this recursive embedding is fairly inefficient and mathematically trivial, it is fully reliable - it always works, even if it takes considerable time and failure.

As Ike continues recursively embedding their regularity, they begin to develop a powerful generalization, first in tandem with their recursive embedding then by itself. First, Ike begins searching for a more efficient gameplay strategy: Ike's frustration with slowness of *operating* on their *regularity*, combined with their developing awareness of the mathematical relationships within the game, has provoked them to seek a more efficient mathematical strategy. In particular, they are trying to identify another *regularity* in order to develop a *transformation* of their generalization that will work consistently across all the puzzles. After solving Puzzle 6 (shown in the right of Figure 1) with their recursive embedding, the researcher asks if they had expected that choice to be correct. Ike replies that they were not sure, because "the scale was a little different than earlier, because it was treating a larger amount of cubes [spreads their fingers vertically and gestures up into the air to indicate they mean the blocks initially present in the hole] as a smaller number." The interviewer asks them to clarify what they mean, and their explanation is illustrated as an enhanced transcript (Figure 1).

Line 1 verifies that Ike used recursive embedding to solve the puzzle when they state that they were not sure if their choice was correct, and that they considered the correct choice just as likely to be the button that was slightly less. When the interviewer prompts them to explain more about their thinking, Ike explains that there is probably a relationship between the buttons and the amount of gold blocks preset by the game (Lines 2-4). In a further explanation not included in Figure 1, Ike went on to say that when the game began, the numbers on the button were larger, because the resulting blocks that would come in were smaller. As the game progressed, however, the buttons began having smaller numbers, but the space that needed to be filled was about the same. Ike first used recursive embedding to solve the puzzle, and their musings afterwards indicated that they were seeking to further unpack and understand the game's underlying mathematical relationships. Later, although space constraints preclude us from including the data excerpts, Ike *searches for* and *identifies a regularity*, and uses that regularity to *establish a way of operating*, as they continue to use this regularity to guide their activity in following puzzles. As the game introduces other variations – such as an overfilled hole, modeling an improper fraction – Ike engages in *extending* in order to *continue* and then *operate* with this generalization.

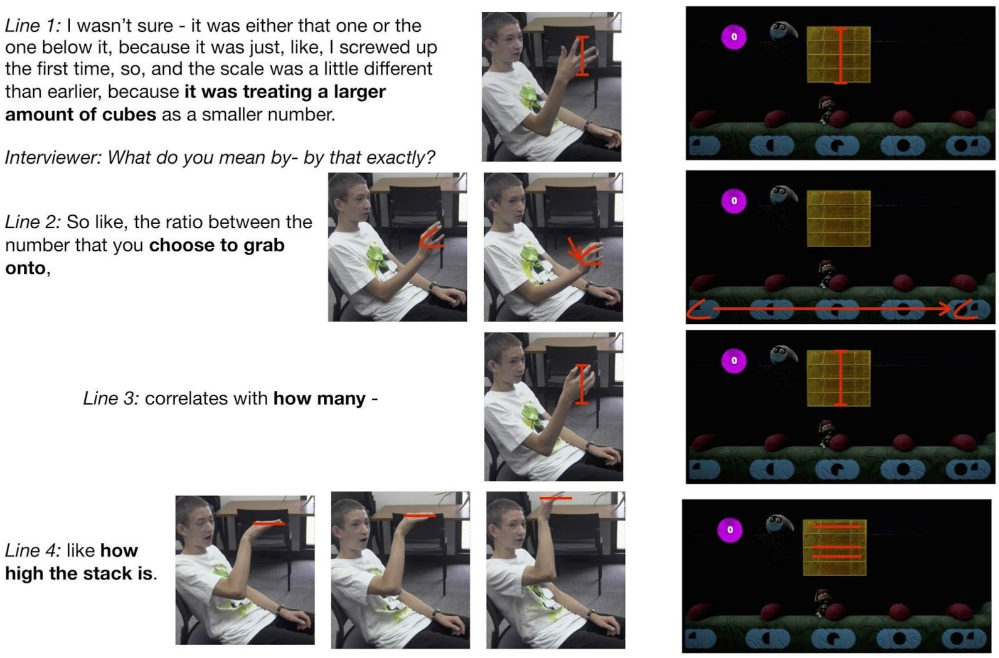

Figure 1: Ike's spoken language with gestures (left). Red maps gestures to the game structures.

Discussion and conclusion

Ellis and colleagues' generalizing framework is rich enough to navigate the distinct differences across context, participant interactions, and artefacts from their research to ours. We identified different ways in which generalizing was mediated in this digital context that directly influenced generalizations. In addition, we found that RA provoked recursive embedding of mathematical activity, as one puzzle provided the foundation for the next puzzle. In other words, we conducted the analysis with the understanding that there is some underlying experience that ties mathematical engagement together across the arc of gameplay and learning. We hypothesize in particular that such designed experiences are likely to increase recursive embedding and may provoke an intellectual need for structure (Harel, 2013) that leads to developing powerful generalizing opportunities. Such intellectual need plays a crucial role in motivating the development of sophisticated generalizations in non-linguistic learning contexts like *RA*, as recursive embedding becomes frustratingly inefficient.

We attended to two types of gestures: the simulated digital actions that result from the player's interaction with the game controller; and the player's physical representational gestures in order to identify which digital structures – and their mathematical counterparts – they are referring to in speech. There is an ebb and flow of different types of evidence during multimodal generalizing. For example, there is a shift in data types being used to support Ike's usage of recursive embedding, depending upon which context – digital or physical – they are primarily focused upon. During gameplay, evidence of recursive embedding can be seen through their spoken language paired with their avatar's digital action – e.g., activating a button, failing, then moving to activate another button. During pauses in gameplay, however, our analysis pairs the spoken language with Ike's physical and representational gestures – that is, how Ike is manifesting their simulated action in a moment when digital action is not occurring. We consider this to be an ebb and flow because although it is tempting to slice the data according to the different modalities – Ike playing the game vs. Ike not playing – each slice is in fact a new layer upon our understanding of Ike's generalizing, and looking at each modality separately disregards Ike's holistic experience. Consequently, we identify multimodal generalizing by threading through these different modalities, and consider physical and digital gestures necessary for investigating such generalizing.

Endnotes

(1) We use *they singular* pronouns to refer to Ike (a pseudonym), as we failed to identify appropriate pronouns for Ike in two important ways. First, we only asked the parent registering the youth participant rather than the youth themselves; and second, we conflated sex and gender by asking "What gender is your child?" We thank Damarin and Erchick (2010) for highlighting the need for *clarity* of such methodological issues in our field.

Centering Praxis in Design-Based Research: Insights from an Informal STEM Research Practice Partnership

Stephanie Hladik, Marie-Claire Shanahan, Pratim Sengupta
skhladik@ucalgary.ca, mcshanah@ucalgary.ca, pratim.sengupta@ucalgary.ca
University of Calgary

Abstract: Design-based research, when taking place within research practice partnership, leads to an essential tension between the interventionist nature of educational design and a commitment to praxis. We encountered this tension within a DBR project to design a computational science exhibit within a science museum, and in this paper, we highlight how paying attention to praxis shifted our epistemological enframings and methodologies of our work. Moving away from a device-centered approach focused solely on the design of the exhibit, we show how listening carefully to museum facilitators led to the recognition of their hidden labor, and helped us to explicitly position the museum facilitators as co-designers.

Introduction and background

Design Based Research (DBR) acknowledges the intertwined nature of educational designs and practice and is expected to lead to contributions in both practice and theory (McKenney & Reeves, 2012). This paper addresses an essential tension at the heart of DBR: rather than focusing exclusively on the interventionist nature of educational design, DBR taking place within Research Practice Partnerships (RPPs) also demands attention to supporting longer-term relationships and understanding the roles and experiences of the researchers and practitioners working together for mutual benefit (Penuel et al., 2015). Our work arises from our lived-in experiences of the tension between these two foci within a multi-year RPP in a science museum, illustrating how the work of the facilitators drew our attention away from the materiality of the designed environment to the complexity of praxis causing a shift in the theoretical and analytical foci of the researchers. Failing to attend to relationships, hierarchies and the meaningful actions of all involved *as part of the design or reform activity*, leaves the status quo intact and constrains the possibilities for real and meaningful change in educational settings (Carlone & Webb, 2006). This is especially important given that informal STEM education scholars rarely focus on the *work* of museum facilitators, and the literature largely views facilitators through a deficit lens and as needing more training (Ji et al., 2016; Tran et al. 2019). The spectre of technocentrism (Papert, 1980) – the fallacy of referring all questions about technology to the technology itself, rather than inquiring about the socially, historically and institutionally constructed meanings and experience of technology – looms large in the field of computing education (Sengupta et al., 2021). This emphasizes device-level engagements (Rosner, 2018; see also Ames, 2019), orienting our attention primarily toward the software/hardware involved, rather than the complexity of the participants' experiences. In informal STEM education research, the emphasis on device-level engagements is evident in the form of a focus on the effectiveness of the designed technologies and exhibits (see for example, Horn et al., 2009), which obscures the complexity of the work of facilitation (Ozacar et al., 2020).

Given this background, our work seeks to identify and understand the work of facilitators in the design process as *mediated praxis* (Gutiérrez & Vossoughi, 2010), where "changes in practice necessarily involve changes in the ways we think about practice [and] individual shifts in thinking and participation influence (and are influenced by) changes in the activity itself." (p. 105). We ask the following **research question**: How did paying attention to the complexity of praxis shift our methodological approach and the underlying epistemological metaphors in design-based research in our work? We argue that *listening* (Schön, 1983) to facilitators' voices plays an essential role in the context of design in informal science centers and museums, and present an investigation of the epistemological and methodological shifts that result from centering their work and their voices in the context of a multi-year RPP. Our work illustrates how, by listening to the facilitators rather than continuing our own, initial, device-centered approach to design, we were able to identify the hidden labor of facilitators. Our work builds on Star and Ruhleder (1996), who argued that support systems or infrastructures that are locally relevant and develop over time are essential to the long-term sustainability of innovations, and that it is often in moments of conflict between or breakdown of these support systems - a phenomenon that they termed "infrastructuring" - that infrastructures become visible. We conclude the paper with a discussion of the epistemological and axiological implications of our methodological shift.

Context, data, and method

This paper reports an ongoing, multi-year RPP with a science museum around the design, visitor experience and facilitation of a public computing exhibit called *Hack the Flock*. At Hack the Flock, visitors can interact with a simulation of flocking, in which boids (bird-droids) continuously shift and flock around the screen, moving in relation to other moving boids according to three forces (Reynolds, 1987): alignment (trying to steer in the same direction as neighbors), cohesion (trying to move towards the centroid of the flock), and separation (trying to keep some distance between itself and other flockmates). Visitors can use the computer terminal to directly change those forces through changing the underlying code and parameters for color, shape, speed, and size, and images.

We collected data in multiple forms: a) field notes of researchers who participated as both facilitators and observers of visitors' interactions, b) video recordings of visitors' and facilitators' interactions with the visualization, code, and other elements of the exhibit, c) interviews with museum facilitators about their experiences with the exhibit, and d) video recordings of museum facilitators taking part in design meetings. Visitor interactions with the exhibit ranged in length from a few minutes to over an hour. We adopted interpretive and phenomenographic approaches for the analysis. Phenomenography focuses on identifying participants' enframing of situations, and an object or an event, in this view, must be interpreted in light of the "complex of the different ways it might be experienced" (Marton & Booth, 1996, p. 538). Our interpretive analysis (Thorne et al., 1996) relied on analytic frameworks to accommodate both participants' enframings as well as disciplinary enframings. In our context, disciplinary enframings included theoretical constructs such as device-level engagements and infrastructuring, and interpretive analysis involved inductively refining the match between our data and the conceptualizations implied by these constructs, which also guided how we selected the cases. Our findings illustrate the chronological shift in our stances from device-centeredness to a more praxis-centered approach, and illustrate how this resulted in us learning to value what we later termed *improvisational infrastructuring* through acknowledging and centering the complexity of praxis in DBR.

Findings

Recognizing infrastructuring

Prior to the installation, our stance was design-based researchers was device-centered, as our focus during the pilot testing phase (Nov 2016 – Jan 2018) was entirely focused on designing and improving software and hardware components of the exhibit based on a series of six user testing sessions, with minimal involvement of the facilitators. After the exhibit was installed in March 2018, collecting initial facilitation and visitor interaction data required the research team and administrators from the science museum to work together, and it was during this phase that we began to notice institutional constraints and expectations that facilitators had to navigate. This was our first encounter with *infrastructuring* (Star & Ruhleder, 1996), i.e., breakdowns in support systems around the exhibit. Firstly, a job requirement for museum facilitators at this science centre was that they were expected to roam around the galleries to help guests and they were not supposed to spend longer periods of time (beyond a few minutes at the most) at any one exhibit. Therefore, collecting video observations of facilitators and visitors working together meant that a facilitator had to be specifically stationed at the exhibit (requiring another facilitator to work and cover their typical duties, atypical for this science museum) and availability of facilitators was adversely affected by shrinking budgets and high turnover – a commonly noted issue in museum education (Moore et al. 2020). Furthermore, inconsistent training sessions meant that some facilitators who were scheduled to spend time at Hack the Flock (and were therefore eligible to consent to be part of the research) had never worked at Hack the Flock previously or received training from researchers or museum staff on the exhibit.

The infrastructuring that resulted from issues was quickly visible as data collection began. Facilitators generally did not like the exhibit, as facilitation was difficult due to lack of experience, time, and training. Some discomfort with the topic of coding and technical difficulties with the first exhibit iteration, such as needing to reset it if a visitor "broke" the code, compounded the negative viewpoint of the exhibit. In fact, before they were scheduled to spend blocks of time at the exhibit, some facilitators actively *avoided* facilitating the exhibit (Interview, Ashley, Jul 2019). Facilitators felt that they had been "thrown into" the exhibit without any training (Interview, Kaitlynn, Aug 2019), the physical interface was difficult to use (multiple facilitator interviews, Jul-Aug 2019), and had only been able to have a few good, extended interactions with visitors (multiple facilitator interviews, Jul-Aug 2019). Thus, their institutional regulations, coupled with negative personal experiences, oriented them away from Hack the Flock. And yet, even in our observations, it became increasingly clear that the most important factor shaping the quality of visitor experiences at Hack the Flock was not the exhibit itself, but the work that facilitators do to support it. We began to notice hidden work that facilitators did while at the exhibit, even in cases where the facilitators themselves had little or no prior experience in working with the exhibit and/or code. It was at this point that our research interests pivoted from exhibit redesign to the hidden work that facilitators were doing to make the exhibit "work" - an ontological innovation (DiSessa & Cobb, 2004) we later termed *facilitator infrastructuring*. This work was largely invisible to the researchers until they spent extended time in the field and strengthened relationships with the facilitators, and we describe this next.

Improvisational infrastructuring as hidden design work, and centering facilitator voice

The complexity of facilitator infrastructuring emerged from their interviews and observations of their interactions with visitors, and a common form of infrastructuring involved improvising in the moment to deal with challenging situations with visitors. For example, Janelle used experimentation – a strategy that she would usually use with other exhibits - when she could not remember the results of a particular code change, noting: "So I'll be like, with a kid when I forget, I just kind of experiment. So I'm like, let's see what happens when we do this. I was like, oh, what if we do the opposite?" (Interview, Jan 2019). Other strategies included selectively emphasizing certain aspects of the code over others, based on the facilitators' own conceptual difficulties with the computational representations and abstractions (e.g., difficulties with "breaking" the code unintentionally) (Interview, Jan 2019). While not voiced as design ideas, these comments provide insight into which aspects of the exhibit were used to draw visitors in or were well-understood by facilitators, and which were confusing. These insights could lead to changes in code order, better explanations of existing lines of code, or new additions to the exhibit that were more "visible" and "fun" for visitors. With continuous prompting from the PhD students, facilitators also offered new design ideas for the exhibit and its surrounding infrastructure based on their experiences facilitating at Hack the Flock. For example, facilitators mentioned wanting more images and a facilitation guide that would be full of explanations and images to help both visitors and facilitators be able to more deeply explore the exhibit.

More important than the design ideas, however, was the creation of a community of practice (Lave & Wenger, 1991) around Hack the Flock that showed promise of persisting even after the researchers had left. Facilitators began to self-organize around the exhibit, creating a sense of community and increasing feelings of ownership, both over the exhibit and in the research project more generally. They were eager to help each other learn about the exhibit, often teaching each other in lieu of formal training or depending on researchers or exhibit designers who were not always available to them: "Even if I can't remember, I can ask my teammates to help me out and we can… all teach each other." (Interview, Ashley, Aug 2019). Facilitators shared new code changes with visitors, the researchers, and other facilitators, both in-person and via institutional and social media, such as when Hilda (July, 2019) created her new "favourite colour" using RGB colour representation and told the researcher to write it down before running off to find another facilitator in the gallery to show off her creation.

Making space for facilitators as co-designers

During Dec 2019, our goal was to run multiple 1-hour design meetings specifically for facilitators so that they could collaboratively reflect on their experiences at Hack the Flock and brainstorm potential solutions to the challenges they voiced throughout the project. Our design meeting had two components: firstly, at the request of facilitators throughout the project, the researchers gave a review of the data they had collected so far, what analyses were ongoing, and what future research directions might look like. For the rest of the time, facilitators worked in small groups to brainstorm exhibit improvements, in which drew upon their extensive experience to make a wide variety of design suggestions, encompassing everything from hardware components and props to new ways of inviting visitors to engage with Hack the Flock. Some suggestions included using a prop from a previous exhibit that explained RGB colour representation; a touchscreen interface, creating challenge cards, easter eggs, competition modes, and ways to save and display work; an easier way to reset broken code; and incorporating explanations of real-world applications of computing (video recordings and written documents, design meetings, Dec 2019). Their understandings of the exhibit extended beyond its hardware and software and were grounded in the need for interaction between visitors and facilitators. These design meetings also provided a space where multiple perspectives on the exhibit could exist simultaneously, such as those from the researchers as well as those of the facilitators who had to work with it on a daily basis. As Jasmine (Video recording, facilitator design meeting, Dec 2019) explained, having the researchers explain why they had designed Hack the Flock to use text-based code in this way and what they were hoping to learn from the exhibit was something she could understand and respect. At the same time, she and other facilitators were having difficulties "jumping right in" to the exhibit with visitors. Understanding and acknowledging these different viewpoints meant that facilitators and researchers could then engage in joint work together to design solutions to problems that could align with both of them - finding new ways for visitors and facilitators to interact with the exhibit that would not compromise the epistemology of computing that researchers wanted to promote.

Discussion: Intertwined shifts in epistemology and methodology

Our findings showcase the ways in which the move away from device-centeredness led to space in which mediated praxis (Gutiérrez & Vossoughi, 2010) could take place, promoting "expansive forms of learning in which individual and collective zones of proximal developments coalesce" (p. 111) and causing both facilitators and researchers to "act a head taller than themselves", moving the current project and the RPP towards a new, future form. The implications for centring praxis are both epistemological and methodological, extending far beyond reductionist accounts of accommodating or negotiating institutional challenges, and bringing into light the hidden labor of practitioners who enliven the designers' innovations. The epistemological shift involved moving away from centring materiality of the exhibit and intentionality of designers to more deeply considering *who* takes part in design, especially given that it is the labor of the facilitators that enlivens the exhibit. From an axiological perspective, one could then reframe the iterative core of DBR in RPPs as an ongoing quest to reflect upon our own roles as researchers and designers in contexts of praxis, by continually seeking to center the hidden complexities of the *labor* that constitutes praxis rather than solely foregrounding designers' intentionalities.

Proposing a Framework for Analyzing Metadiscourse in Dialogic Science Classrooms

Mon-Lin Monica Ko, University of Illinois at Chicago, mlko@uic.edu
Melissa J. Luna, West Virginia University, melissa.luna@mail.wvu.edu

Abstract: Classroom discussions have become a centerpiece of reform efforts in science classrooms, yet there are recurring challenges to understanding how teachers and students engage, and make sense of classroom discussion to support knowledge building. In this paper, we present a framework for analyzing the metadiscourse (MD) used during discussions, building on prior work on the use of MD in academic writing. We argue here that while other analytic systems for classroom dialogue rely primarily on a speaker's *propositional content*, the speaker's use of MD can also shed light on how teachers and students are positioning themselves and their ideas during discussion. We provide an overview of our framework, illustrate its application, and discuss implications for analyzing discussions in K-12 classrooms.

Challenges in the analysis of verbal discourse in science classrooms

In the United States and elsewhere, there has been an increasing focus on moving away from monologic, didactic science instruction and towards co-construction and knowledge building through classroom dialogue (e.g. Berland et al., 2016). In order to apprentice students into disciplinary practice, classroom talk must reflect the dialogic, interactive, and social work that scientific knowledge building requires. Researchers utilizing frame, conversation, and interaction analysis to analyze discussions point out that teachers and students interpret and engage in meaning-making talk differently, and that these differences directly influence students' participation in disciplinary practices (e.g. Russ, 2018). This body of work has revealed several challenges to understanding what it is that's going on when discussions take place during science instruction, especially in regarding students' agency and teacher's authority (e.g. Miller et al., 2018). This prior scholarship suggests that talking past one another, using different resources, epistemic commitments and goals is probably more prevalent than we think. Here, we argue that while metadiscourse (MD) plays a vital role in how teachers and students engage in sensemaking and knowledge building, it is often overlooked in analyses of such talk. We therefore propose an analytical framework for MD that can be applied to talk in highly dialogic science classrooms.

Metadiscourse (MD): Definition and function in written text

The framework we propose builds on existing scholarship in fields of Systemic Functional Linguistics on the use of MD in written text. MD is defined as "the interpersonal resources used to organize a discourse or writer's stance toward either its content or the reader" (Hyland, 2000, p.109). Given our focus on verbal text, our concern is with a *speaker* and their *audience*. In this context, MD is not the "substance" of the ideas that a speaker puts forward, but rather, the language that surrounds it that, intentionally or unintentionally, shapes the audience's sensemaking of the content proposed. Tang (2017) writes that MD "is always present in most conversations...its function is to assist the audience to connect, interpret, organize, and evaluate the content in the talk in a way preferred by the author or aligned with the social conventions and values of the discourse community" (p. 2). Hyland and Tse (2004) argue that MD 1) is distinct from propositional content; 2) refers to those aspects of the text that embody writer-reader interactions; and 3) distinguishes relations which are external to the text from those that are internal. In applying these frameworks to verbal text, we replace the emphasis on *writer* and *readers* with a *speaker* and *their audience*. These 3 principles suggest that in the context of verbal discourse, MD can signal a speaker's attitudes and commitments, and in turn, shape the way that knowledge building unfolds in a science classroom.

Significance: Analyzing the use of metadiscourse (MD) in verbal text

Although there is extant work on the use of MD in written text, research into MD in verbal talk is limited in science education. The exception to this is work by Tang (2017), who proposed an analytic framework based on an analysis of teacher talk in a classroom where content was delivered predominantly through direct instruction. Here, we build on this work and explore how MD is used in dialogic classrooms. Our framework advances methods for analyzing the role of non-propositional content in shaping sensemaking and knowledge building talk, thereby making visible the nuanced ways in which teachers and students co-construct scientific knowledge.

Methodological approach

Selection of classroom episodes for analysis
To develop our framework, we selected four episodes of classroom talk from a 3rd, 5th, and two 6th grade science lessons from reform-oriented curricula that focus on phenomenon-driven inquiry and co-constructing knowledge through discussions (Lawrence Hall of Science, 1993-2016; Kracjik et al, 2013). We selected these episodes because they had been previously identified as discourse that reflected shifts in how teachers and students positioned themselves, their ideas, and their goals (Ko & Elby, 2018; Richards et al., 2020). For each episode, we conducted a turn-by-turn analysis to characterize the MD in teacher and student talk. Four transcripts consisting of 35 minutes of classroom discussion were analyzed to develop this framework.

Development of the analytic scheme
The framework presented here has three levels of codes, *Type*, *Category*, and *Subcategory*. The definitions and examples of these codes were derived from two phases of analysis, described below.

<u>Phase 1: Developing consensus on the Types and Categories of MD (Level I and II)</u>
In the first phase, we used the MD markers identified in the field of Systemic Functional Linguistics (Hyland & Tse, 2004, and recently, Tang, 2017) as provisional codes (Saldaña, 2013). This scheme has 3 levels, moving from most general to most specific: 1) *Type*, 2) *Category*, and 3) *Subcategory* of MD. The authors examined an eight-minute episode from an elementary science classroom to identify potential MD markers, and then coded each marker as an Organizational or Interpretive MD, based on the function of the MD in the context of the whole group discussion. Due to the contingent nature of classroom talk, we referred to at least 5 turns of talk that preceded and followed each turn (Schaffer, 2017) to come to consensus. After exhausting the codes with this data set and reaching consensus on the preliminary definitions, we independently coded ~100 turns of talk and discussed our codes and resolved discrepancies to develop greater consensus around the *Types* of MD and their associated *Categories*. We then independently coded an additional 40 turns of talk; we made note of MD markers that were inconclusive, generated a set of issues that needed to be discussed, and refined the existing code definitions to be more reflective of how MD functions within verbal talk. We also compared our analysis with those MD markers that have been commonly identified in written text (e.g. https://textinspector.com/) in the same eight-minute episode. This comparison revealed that we uncovered a wide range of MD markers that were not identified in the existing literature. In other words, the general frameworks from existing literature could not adequately capture the range of MD used during dialogic whole group discussion. This first phase of analysis generated consensus around the two levels of codes (*Types* and *Categories*) and refined our codes and their definitions to more accurately reflect how MD is used in dialogic conversations in science classrooms.

<u>Phase 2: Developing consensus around Subcategories of MD (Levels III)</u>
In the second phase of analysis, we engaged in axial coding (Saldaña, 2013) to (1) reorganize and extend our existing *Type* and *Category* codes, and (2) reach code and meaning saturation for all *Subcategories* of MD. To do this, we located the turns of talk containing a high density of MD in 4 excerpts from the 4 selected lessons. From there, we sought to identify multiple examples of each *Subcategory* of MD. The axial coding was done independently, so that we could identify discrepancies, make note of questions, and develop a set of criteria for making coding decisions across classroom contexts and content areas. Two or more exemplars for each *Subcategory* in both teacher and student turns of talk were identified. We jointly and independently coded until we reached code saturation, and then coded independently to reach meaning saturation across the 4 excerpts. The axial coding resulted in an expansion of *Subcategories* of MD. Three of Tang's *Subcategories* were eliminated from our framework because we were not able to apply them to our classroom data. Of the 22 *Subcategories*, then, 15 were similar to the subcategories in Tang's framework while seven were new altogether. Finally, we pulled out a subset of *Category* and *Subcategory* codes and organized them as a third Type of MD—*Epistemic MD*, to more prominently feature the role of these types of MD in signaling both what counts as a resource and whose ideas are valued during knowledge-building. In summary, this two-phase process led to a refinement, consolidation and reorganization of pre-existing frameworks for analyzing MD to more closely approximate the use of MD by teachers and students in dialogic classrooms. These two phases of analysis resulted in 3 *Types*, 7 *Categories*, and 22 *Subcategories* of MD markers.

Findings: A framework for analyzing MD in science classroom talk
While the full analytical framework includes definitions of each *Type* and *Category*, describes the function of each *Subcategory*, and provides at least two examples from our data for all 22 possible code combinations, the

limitations of a proposal make presenting the full framework impractical. Therefore, in this section we first provide a summary of the analytical framework showing the 3 *Types*, 7 *Categories*, and 22 *Subcategories* of MD the framework captures (Table 1). We then show an application of the framework on two turns of classroom talk. The conference presentation will include the full analytical framework with definitions, functions, and examples of all the codes, as well as further applications of the framework across more extended excerpts of classroom talk.

Table 1: Summary of analytical framework for MD with 3 *Types*, 7 *Categories*, and 22 *Subcategories*

Types of Metadiscourse and Description	**Organizational MD:** Signals different parts of the talk to guide participants through the (verbal) text. Also signals ways of engaging in conversation.	**Epistemic MD:** Signals the resources recruited (who and what) in the knowledge building process.	**Interpretive MD:** Signals an expectation, attitude, or point of view toward the propositional content.
Categories (7) and Subcategories (22)	Text Connective: Topicalizer, Sequencer, Revoice/Restate Activity Connective: Actionizer, Stringer Frame Marker: Earlier Conversation, Future Conversation, Transition, Previous Activity, External Activity	Evidentials: Sensory Experience, Material Stuff, Scientists'/Canonical Knowledge, Personal Beliefs/ Ideas Agents: Collaborative/Collective, Individual	Engagement: Participation, Translation Stance: Qualifier, Importance, Challenge, Emoter

An illustration of our coding scheme in action

To illustrate our analytic flow, we use two turns of talk from our data to highlight instances of MD evident in the talk and reason through their functions. Henceforth, we use the following conventions to highlight the MD markers in each turn of talk: Organizational MD is **bolded** text, Epistemic MD is *italicized* text, and Interpretive MD is underlined text. We then elaborate on the rationale that warrants the codes we applied at each level.

Table 2: *Types*, *Categories*, and *Subcategories* of MD in two turns of talk from an EL science lesson

Turn of talk (Organizational, *Epistemic*, Interpretive)	**MD markers identified**	**Type**	**Category**	**Subcategory**
Teacher: Shhh, listen. Listen to **his ideas**, okay?	Shhh	Interpretive	Engagement	Participation
	his ideas	Organizational	Text Connective	Topicalizer
Student (Leo): Ricky, *he says*, "oh maybe they um, or maybe' *they put* like um batteries or energy *so it could* move up or down.	he says	Epistemic	Evidentials	Personal Beliefs/Ideas
	maybe; maybe	Interpretive	Stance	Qualifier (Hedge)
	they put	Epistemic	Evidentials	Sensory Experience
	so it could	Epistemic	Evidentials	Material Stuff

In these two turns of talk, we identified six instances of MD being used—two instances by the teacher and four others by a student (Leo). Prior to these turns, one student had put forth the idea that batteries or energy are what cause the red liquid to move inside a thermometer. As the conversation continued, the teacher uses MD to first signal how she wants the students to engage in the discussion—by being quiet (Shhh), and focused on Leo's proposal (**his ideas**). The first instance serves an interpretive purpose, because the MD marker indicates the forms of participation that are encouraged by the teacher at that moment, while the second instance serves an organizational one, because Leo's ideas now have become the focus of attention. In the next turn, Leo uses MD to make references to another student's (Ricky's) earlier idea (*he says*), indicating a sense of uncertainty about the idea (maybe; maybe). The MD *They put* indicates someone's tactile experience, and, *so it could* indicates how the source of energy (batteries or energy) functions (by moving the red liquid up or down). Three of these instances of MD signal the resources that Leo is building off of—Ricky's idea, the tactile experience of using a battery—to support a claim about why the liquid moves up and down in the thermometer.

Conclusion and implications: How this framework can be taken up to understand and support sense-making in science classrooms

In this study, we proposed a framework for analyzing MD markers in whole group discussions, with the goal of bolstering existing methods for detecting how teachers and students are participating in knowledge-building talk in science classrooms. While there are numerous frameworks that have been developed for analyzing science classroom talk, these existing systems rely heavily on the propositional content that is put forth by a speaker to make inferences about how teachers and students are framing the classroom activity. Yet we argue that MD also plays an important role in classroom talk and that we need to include it in the analyses of classroom discourse. MD markers can help participants determine, among other things, what propositional content to focus on, how to engage with each other and the propositional content, and what resources are at play in the knowledge-building talk. And although MD markers have been intensively studied and supported in written text, there have been few studies that have systematically identified MD in dialogic discussions, or considered the role of MD relative to existing discourse analysis frameworks. We see the analysis of MD markers as complementery to coding done at the level of consecutive turns or episodes, which together can lead to increasingly thick descriptions of classroom events. With additional applications and refinement, we see our framework as a rich contribution to analytic methods that can be used to elucidate how teachers and students take up the work of co-constructing knowledge.

Abstract: What is assessed drives what is valued, taught, and learned by teachers and students. This paper reviews the approaches proposed for assessing student design (processes and outcomes) in STEM courses to help inform the increasing focus on design in STEM curricula. We began with the goal of reviewing such approaches across 17 prominent journals that address STEM and design education. Database searches resulted in 2101 raw hits and an ultimate sample of 27 articles, predominantly in engineering education. We performed a content analysis to identify key assessment foci. The majority (20) included a focus on performance of the design, and a substantial number included a focus on communication (15) and scoping (11). While less prevalent, divergent thinking (9), creativity (9), convergent thinking (8), and collaboration (8) were also broadly represented. Ethical considerations were not strongly represented in the reviewed assessments, although there were important exceptions.

Introduction

In STEM education, there is increased attention to "design," both as a disciplinary practice and a pedagogical approach. Given the interdisciplinary nature of design, research on design learning and assessment has been conducted in an array of disciplinary journals. Our goal was to identify peer-reviewed articles about design assessment and to analyze how educators assess students' design artifacts and practices in STEM and design education. We explored the following questions: (a) what aspects of the design process and/or outcomes are assessed, (b) what approaches are used to assess design, (c) at what granularity are the assessments conducted, (d) who is involved in the assessment process, and (e) what age groups of students are the focus. To evaluate the status of assessment of design in STEM education, we performed a systematized literature review (Grant & Booth, 2009) and content analysis across seventeen leading journals that address STEM and design education based on Journal Citation Reports (JCR), Scientific Journal Rankings (SJR), and h-index statistics.

Theoretical framing

The structure, content, and scope of assessment drive what is valued, taught, and learned by teachers and students (e.g., Entwhistle & Peterson, 2004; Jürges, Schneider, Senkbeil, & Carstensen, 2012). Because of the increasing role of design in STEM curricula it is therefore of great importance to review the approaches proposed for assessing design given its multifaceted nature. Design educators, recognizing the importance of and the challenges in assessing informed design practices, have developed instruments for assessing students' knowledge of and practices in design (Atman, Chimka, Bursic, & Nachtmann, 1999; Bailey & Szabo, 2007). In design education, assessment of design outcomes (products, artifacts, or systems) is also important. Design outcomes need to achieve high quality while attending to competing criteria and constraints. Purzer et al. (2016) introduce the concept of trade-off value when evaluating student design artifacts. One of the challenges student designers face is balancing competing design criteria such as feasibility and novelty (Oman, Tumer, Wood, & Seepersad, 2012; Shah, Woodward, & Smith, 2013). Studies show that undergraduate engineering students skew toward novelty in their first year in college, while the balance switches toward technical feasibility in the final years (Genco, Hölttä-Otto, & Seepersad, 2012). The purpose of this review is to better understand how assessment practices attend to these multifaceted aspects of design processes and design outcomes.

Methods and search criteria

We bounded our review to articles published between 2002 through August 2018. Given the common use of the terms "design" and "assessment" in research beyond the scope of our study, we identified 17 specific journals as opposed to a broad search within selected databases. We searched across four databases (i.e., ASC, ERC, ERIC, and AA) indexed the 17 specific journals we targeted. We used the following search terms and Boolean operators at the abstract and title level: (Design* OR Ideation OR Creativity) AND (Assess* OR Rubric OR Framework OR (Coding Scheme) OR Measure OR Metric OR Instrument OR Method). This scan resulted in 2101 raw hits across the 17 journals. Our team identified several inclusion criteria in iterative discussions, including the proposition, presentation, or validation of an assessment framework, or sufficient theoretical warranting (a full list of criteria will be included in the journal publication). Articles that straddled the borders of the inclusion criteria were reviewed at the abstract level by the group for a final decision. We then reviewed the main-text of each article and evaluated whether the assessment instruments therein were described in sufficient detail to meet the criteria. The literature search resulted in a sample of 27 articles: 23 from engineering education journals and 4 from a design journal. We performed a content analysis of the final 27 articles to identify key components of assessment.

Results and interpretations

In our inductive coding, categories arose around multiple aspects of design, including: (i) problem scoping, (ii) divergent thinking, (iii) creativity, (iv) design performance and functionality, (v) convergent thinking, (vi) collaboration, and (vii) communication. While these seven categories were generally distinct, the clearest distinctions involved design performance, communication, and collaboration, while the distinction between divergent thinking and creativity was the least clear in many cases. This is complicated by terminology that is often used interchangeably in the literature (e.g., originality and novelty).

Most of the assessment approaches addressed multiple categories (2.96 out of 7 categories on average). Among the 27 articles, the majority (20) included a focus on assessing design performance, and a substantial number included a focus on assessing communication (15) followed by problem scoping (11). While less prevalent, divergent thinking (9), creativity (9), convergent thinking (8), and collaboration (8) were also broadly represented (Table 1). Notably, most articles assessed the performance or function of a final design outcome but the processes of design were not always assessed. We speculate the logistics of assessing a final design are often easier for instructors than assessing intangible or real-time aspects of the design process in the midst of running a class or perhaps the assessment of design processes is done in implicit ways with a formative intent. Undoubtedly, the processes of design are as important as final projects as argued in prior research (see Atman et al., 1999), but we recognize that the pragmatic realities of facilitating and teaching a class may challenge the bandwidth to conduct simultaneous real-time assessments of process. There is work underway to collect real-time process data digitally to automate assessment of process (e.g., Worsley & Blikstein, 2016; Xie et al., 2014), which may change the nature of assessment of design radically in the future, but these approaches are not yet scalable. These digital tools can help complement, extend, or add depth to what is currently feasible.

One major influence on assessment foci are professional engineering organizations, particularly the Accreditation Board for Engineering and Technology (ABET). Within the 2019-20 ABET definition of Engineering Design, we see a strong alignment with the aspects of design highlighted by our coding of the assessments in terms of problem scoping (e.g., identifying opportunities and developing requirements), creativity (e.g., creative decision-making processes), design performance and functionality (e.g., meeting needs and specifications), ideation (e.g., generating multiple solutions), convergent thinking (e.g., evaluating solutions against requirements). Collaboration (e.g., ability to function effectively on a team) and communication (e.g., ability to communicate ideas and technical information effectively with a range of audiences) are key ideas represented in the specified ABET criteria for student outcomes. Interestingly, creativity is not specified within the 2019-20 student outcome criteria, although it is included within the definition of engineering design. That said, historically creativity has been even less represented in the criteria and definitions.

Aspects of ABET that are less extensively represented in the reviewed assessments include conducting experiments, applying science and mathematics, and information literacy/life-long learning. Engineering ethics and ethical considerations seem to be the very least represented, although there are exceptions. Berry (2010), for example, focused heavily in their approach to Calibrated Peer Review on having the students write a social impact document using the IEEE Code of Ethics as the rubric. Other assessments may include some aspect of attending to ethical issues as part of the task but not as a major aspect of the assessment rubrics themselves. While beyond the scope of this review, we find such omissions troubling given the very real impacts design can have on people's lives. For example, designers can face heavy ideological and ethical dilemmas when engineering products that are used in warfare (Philip, Gupta, Elby, & Turpen, 2018) or to marginalize specific populations (Chellew, 2019). This seems to be an area for future growth in the assessments. While not an assessment of students' actual designs, the approach outlined by Christensen, Hjorth, Iversen, and Blikstein (2016) assesses students' stance toward inquiry in a way that attends to the complexity inherent in wicked problems in terms of social and ethical dimensions among others.

In terms of how assessment is conceptualized and operationalized, most articles described summative rather than formative assessment procedures. We surmise this stems from a combination of formative assessments often being less formal (e.g., undocumented verbal commentary from an instructor circulating among students), traditional preferences to summative assessments in STEM education, and an interest in supporting accreditation processes (e.g., ABET).

For demographics, we anticipated undergraduate education would be the predominant focus of the assessments but were surprised by the limited focus at the K-12 level given the increasing interest and emphasis in K-12 education on design, design thinking, and engineering. There are many excellent studies of K-12 student design that are not focused on "assessment" or where design-based learning uses design as a pedagogy and hence their assessment focuses on student learning of science concepts (e.g., Crismond, 2001; Hmelo, Holton, Kolodner, 2000; Kolodner et al., 2003.). In terms of evaluators, there was the integration of multiple types of assessor (2.04 on average). Instructors and TAs were involved in almost all of the assessments (25 of 27), but most (18) of the assessments also involved other people including peers (12), self-assessments (9), and external disciplinary experts (9).

In terms of approach, the assessments primarily depend on the application of rubrics. Some articles do not provide enough information about their rubrics to be reliably applied by others, but many of the articles engage in a high degree of granularity with highly descriptive rubrics. Some of the assessments leverage complex approaches and mathematics within the assessment to create a final numerical score with great precision, but this apparent precision is necessarily limited because the input numbers are based, at times, on highly subjective and underspecified criteria. Another group of the assessments are more subjective in their orientation from beginning to end. Sometimes this has the advantage of not artificially systematizing the process, but greater specification within the rubric criteria would likely most improve the rigor and reliability of the assessment processes we reviewed.

Educational importance of the study

The approaches used to assess design varied based on area of focus but mostly targeted undergraduate education. Among the 27 articles, the majority included a focus on performance assessment, and a substantial number included a focus on communication and problem scoping. While not as prevalent, divergent thinking, creativity, convergent thinking, and collaboration were also broadly represented. Engineering ethics and ethical considerations seem to be the very least represented, although there are exceptions. What is assessed greatly influences what is taught and learned, and careful attention to these less represented aspects of design will therefore be an important area for future development for assessment as design takes on an increasingly central role in STEM education.

Contributions of a Situative Perspective on Motivation in the Learning Sciences: Theorizing Motivation for Youth Voice and Equity

Karlyn R. Adams-Wiggins, Portland State University, karlyn@pdx.edu
Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu

Abstract: While productive disciplinary engagement has remained a key construct in the learning sciences, there has been limited exploration regarding what motivates learning activities. Accordingly, little is understood about purportedly "disengaged" youth who do not readily take up normative practices in learning environments designed with productive disciplinary engagement as a goal. In an attempt to bridge this gap and promote reflection of "disengaged" youth, we argue for embracing the more recent situative perspective on motivation. Further, we propose that tensions between authority and accountability in science education be examined in relation to power, arguing that connecting the situative perspective on motivation should be paired with a youth voice lens. Future directions for research are discussed.

Introduction

Recent research in the learning sciences has highlighted the importance of understanding learners' productive disciplinary engagement as intertwined with questions of identity, power, and positionality (e.g. Adams-Wiggins, 2020; Agarwal & Sengupta-Irvin, 2019; Carlone, 2017; Nasir, 2011). Similarly, some motivation researchers have begun to take up the call for attention to power and positionality. This has been referred to as a *situative perspective on motivation* and it has been outlined using arguments directly from the learning sciences (Nolen & Ward, 2008; Nolen et al., 2015; Nolen, 2020a, 2020b). In the current paper, we interrogate points of convergence and divergence in the situative perspective on motivation and perspectives in the learning sciences that aim to address similar sets of phenomena, namely the relationship between identity and productive disciplinary engagement. We do this specifically with the goal of understanding how motivation can be explored within the learning sciences and developing additional tools to understand youth experiences in learning environments. Motivation is understood as conceptually related to cognitive engagement, but is meaningfully separable: high-quality motivation is insufficient without opportunities for engagement and opportunities to engage may not be taken up by a learner who is not motivated to engage (Blumenfeld et al., 2005). Accordingly, we rely on science education as a context for this discussion and focus on the experiences of youth seen as "disengaged", "unmotivated", or "disidentified". The present paper is intended to promote reflection on the experiences of youth who experience disconnection from learning environments designed to promote learners' productive disciplinary engagement and the youth whose access to science identities is questioned by other people in the classroom itself (Adams-Wiggins et al., 2020; Tierney, 2020). The following sections of this paper offer an introductory situative motivational analysis of the role of youth voice, specifically in connection with a key feature of learning environments: disciplinary authority.

We propose that a situative perspective on motivation provides multiple benefits to those in the learning sciences who want to understand the role of learners' interests, values, identities, and self-perceptions. First, by applying a situative theory of motivation to understanding learning in reform-oriented learning environments, we gain insights into an under-addressed flipside of productive disciplinary engagement in reform-oriented learning environments. In reform-oriented science learning environments, engagement in scientific practices like engaging in argument from evidence and constructing explanations become an important priority (NRC, 2012). While the learning sciences as a field is indeed defined by a focus on "explaining learning" (Kolodner, 2004), we argue that to explain learning we also need to better understand what is happening for youth in reform-oriented contexts who do not necessarily "jump on board" with these curricula and reflect resistance or what researchers typically understand as "low-quality motivation" or "low levels of engagement". In a benefit related to our concern with explaining and improving the experiences of youth who do not readily embody expected forms of engagement in reform-oriented learning environments, the situative perspective on motivation explicitly focuses on questions of power and positionality. A key part of improving these youths' experiences is rejecting deficit perspectives: deficit perspectives propose cultural deficiencies as an explanation for youth of color's behavior in school and promote individualist solutions to promote academic achievement (Valencia, 1997). As an alternative to deficit perspectives, recent arguments from Agarwal and Sengupta-Irvin (2019), Bang (2012), and McKinney de Royston and Sengupta-Irvin (2019) highlight how engagement, motivation, and identification with science as a discipline cannot be separated from the broader context of power relations in a given society. Considering the matter of broader power relations, youths' own perspectives are often missing from discussions of how to best facilitate learning; this is in tension with the goal of ensuring critiques of claims and accountability to disciplinary norms are present in science classrooms, where youth are asked to think like scientists (Engle & Conant, 2002; Ford, 2008).

Redefining labels: "Unmotivated" and "disengaged"

Before moving forward, we want to name limits of language around youth who are not participating in the ways we wish to see them participate. Typically, students are assigned labels such as "unmotivated" and "disengaged". On a larger scale, youth can then be given labels such as "at-risk" (Tierney, 2018). However, scholars have shown the ways in which definitions of success are created and perpetuated in schools (Baines, 2014; McDermott et al., 2006; Willis, 1981). These studies show how the definitions of success are embedded in the contexts and structures of the schools in which they exist; definitions of success do not exist in a vacuum. When considering students who are labeled as "unmotivated", "disengaged," or alienated in school (Dean, 1961; Galbo, 1980), students who are academically unsuccessful, students defined as "at-risk" (be it due to failing grades, drug use, etc.) (Vadeboncoeur & Portes, 2002), and students who are marginalized and disenfranchised (te Riele, 2006), it is important to contextualize these students' motivation and engagement within the specific school and classroom contexts in which this occurs. We approach our work recognizing the pervasive challenge of negative or outsider labels such as "at-risk", "unmotivated", and "disengaged". What often becomes deemphasized with these labels is the valued practices from which youth are "disengaging". Youth are "disengaged" and "unmotivated" for the prioritized tasks teachers present and youth are "at-risk" of not reaching the predetermined goals and definitions of success that exist in schools. However, even in reform-oriented learning environments, which are often student-centered and focused on equitable learning, labels of "disengaged" or "unmotivated" do not automatically lead to an interrogation of the tasks and communities youth are "disengaging" from to understand why and how to improve them. Instead, these labels become linked to the youth themselves, where, at best, youth are provided different learning environments or additional resources and, at worst, are discarded or fully assigned the onus of change (Raywid, 1999; te Riele, 2007; Tierney, 2018; Vadeboncoeur & Portes, 2002).

The relevance of a situative view on motivation in the learning sciences: Extending perspectives on disciplinary authority

Situative perspectives on motivation reconceptualize context such that individuals and contexts are not split in a dualistic fashion; further, identity and forms of participation are key components in any situative account of motivation (Nolen et al., 2015). Sociocultural perspectives on learning and participation, prevalent within the learning sciences as a field, explore the ways that learning and development are created through interactions between individuals and the contexts in which individuals participate (Wenger, 1998). Similarly, identity is not just an internal construct, but something created as individuals participate in the world. Within the learning sciences, engagement has often been used as a placeholder for motivation, a way to understand why individuals participate the way they do (Nasir & Hand, 2008; Nolen, Ward, & Horn, 2011). One result of focusing on a sociocultural definition of engagement is that it examines the processes that occur between individuals and their environments and not just processes that exist within individuals' heads, as is historically the case for motivation literature. In that way, a learning sciences perspective is that to increase engagement, educators should redesign the learning environment to better support engagement. Engagement is not owned solely by the individuals who are seen as disengaged.

Encouraging youth to think like scientists often produces unbalanced uptake of normative scientific practices among youth within a classroom, with those who successfully take up normative scientific practices acquiring *authority* and *ownership of ideas* as their perspectives are validated by teachers and peers (Cornelius & Herrenkohl, 2004). Yet, the youth we prioritize in the present discussion may not experience a sense of ownership or authority, as authority is itself negotiated on the basis of more than just correctness of ideas (Engle et al., 2014). We propose that a situative motivation perspective explicitly incorporating a youth voice lens would enable deepened investigation into how "unmotivated"/"disengaged" students see authority and accountability operating in their learning environments. A situative motivation perspective applying the lens of youth voice would consider these youths own pre-existing interests, goals, values, and expectations as relevant to how these youth negotiate opportunities for participation and whether they see authority as possible and worthwhile given their understanding of who in the classroom actually is positioned as sufficiently accountable to disciplinary norms as authority is negotiated. Further, in order to understand the conditions under which youth will see developing their own disciplinary as both possible and worth their time, we propose that a situative motivation perspective prioritizing youth voice should ask questions about how relevant curricular content is to the lives of "unmotivated"/"disengaged" students. Recent research related to constructs like critical science agency has already begun to consider this matter, but research on motivation in the learning sciences should address this directly, as well.

Conclusions

In sum, a synthesis of recent equity-oriented perspectives on productive disciplinary engagement with existing situative perspectives on motivation suggests an importance of youth voice in conceptualizing motivation in the learning sciences. Addressing the question of situated motivation in learning environments from a youth voice lens can provide important insights that should be integrated into the design process, ensuring these youth are not relegated to invisibility in the learning sciences literature. We argue that both educational psychology and the learning sciences stand to benefit from further elaborating the situative perspective on motivation through a youth voice lens. Further engagement with educational psychology's situative perspective on motivation can offer insights into the learning of youth who do not readily take up designers and teachers' intended forms of participation in reform-oriented learning environments; this contribution will be enhanced by an emphasis on youth voice. The situative perspective on motivation could be a powerful tool for understanding how individual youths' understandings interface with prescribed forms of participation in the activity systems where learning is intended to happen. A situative perspective oriented toward youth voice would intentionally examine youths' resistance and frustrations in addition to productive disciplinary engagement, seeking to understand what provides a sense of ownership and authority for youth on the margins of a science community. Recent research in inquiry science classrooms has already highlighted the unexpected ways that small group collaboration common in inquiry-based science classrooms can involve questioning competence and involves some youth deferring to peers perceived as highly competent rather than cognitively engaging (Adams-Wiggins et al., 2020). These kinds of hurdles to productive disciplinary engagement and identity-in-practice may not be visible in observational research unless verbally recognized by the youth during group talk. More studies are needed to explain the relationship between individual-level meaning-making about group-level activity and forms of engagement youth pursue in the classroom.

In line with relational and practice-oriented perspectives on identity typical in the learning sciences, a situative perspective on motivation could serve as an analytical tool for examining relationships between individual and group level processes: while traditional theories of motivation generally retain a split between the social and the cognitive, a situative perspective leaves room for understanding not only youths' *actions* as forms of engagement, but also youths' contextualized intentions, goal directedness, values, and construals regarding activity in the learning environment as important contributors to youths' pursuit of further forms of participation. Doing so, we aim to foster a conversation regarding how to both deepen the situative perspective on motivation in light of advances from learning sciences theory and empirical research as well as maintain an equity-oriented lens on learning to better promote the interests of youth who are often understood as "disengaged", "unmotivated", or "disidentified" (te Riele, 2007). We hope that by exploring situated motivation within the context of theories from the Learning Sciences that we can better attune to youths' motivations, specifically youth who are not motivated to complete situated tasks or participate in situated communities. We believe this information will support the iterative design of reform-oriented learning environments, while contributing to conversations around motivation and engagement within the Learning Sciences.

Investigating the Nature of Learners' Feedback Seeking Actions and its Role in the Development of Representational Competence

Narasimha Swamy, Chandan Dasgupta

Indian Institute of Technology Bombay

Abstract: Feedback seeking actions are learner initiated dialogic actions aimed at attaining learning goals during an instructional activity. Nature of these actions are complex during representational problem solving as learners have to use or generate multiple representations for the purpose of seeking feedback. Our focus contrasts with the predominant approaches to develop learners' feedback and representational competences as they are unsustainable and undermine the need to develop learners' agency alongside those competences. Currently the question of under what conditions do individuals proactively seek feedback or when and how such actions contribute to specific learning is being investigated primarily in organizational studies. Therefore drawing from these studies, we adapt a well-established cost-value framework of feedback seeking by aligning it with the cultural historical activity theory. We then use this framework to examine how instructional conditions influence learners' feedback seeking actions and the role of such actions in developing their representational competence.

Rationale

Feedback in education is largely viewed as a teacher driven practice involving one-way transmission of performance related information to learners. However, an individual in an authentic context often faces multiple feedback sources, representations, tools and norms (Blunden, 2010; Nicol, 2013). Hence feedback occurs mostly as a result of dialogue with multiple community sources. And during complex tasks such feedback dialogue presents numerous opportunities for developing one's representational competence (Engeström, 2014; Rau, 2020). Here by representational competence, we refer to a range of abilities to work with multiple representations of real or imaginary phenomena for addressing one's thinking, communication and problem solving needs. The challenge of meeting one's diverse feedback needs or more specifically feedback seeking during complex tasks is manifold. It involves identifying potential feedback sources from the community, eliciting and judging feedback from them, using multiple representations or tools for fluently negotiating one's feedback needs; and responding to the different or sometimes conflicting feedback being received by considering each other's emotional, motivational and identity aspects and all the while being sensitive to both implicit and explicit community norms (Engeström, 2014; Nicol, 2013).

Understanding how employees navigate above challenges to accomplish various professional goals has been a major concern in organizational studies for decades. Meta-analytic review of these studies show that the employees' perceived cost-value estimates predominantly guide their actions such as timing, purpose, mode or amount of feedback seeking (Anseel et al., 2015). However, feedback seeking in these studies is currently conceptualized as preferences or choices for different feedback types and opportunities without examining the actual feedback seeking act. Hence reciprocal and iterative nature of feedback seeking dialogue is unaccounted for both in research and practice. Besides, the focus is also on how specific characteristics of a task, situation, feedback sources and self contribute to one's cost-value perceptions rather than on the complex interaction between them. This has left complexities arising due to cultural diversity in relation to feedback seeking poorly addressed. Our attempt at connecting and addressing these issues from both the domains led to the adaptation of the cost-value framework of feedback seeking using cultural historical activity theory as shown in figure 1.

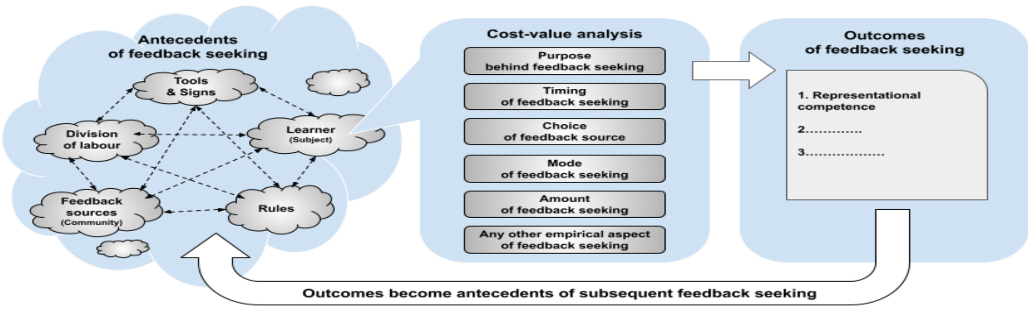

Figure 1. Conceptual framework for studying learners' feedback seeking actions.

As per our adaptation, the interaction between different factors tied to the instructional context referred under 'antecedents of feedback seeking' mediate the learner's (subject) perceptions of cost and value regarding their various feedback seeking actions listed under 'cost-value analysis'. The different factors tied to the instructional context include tools and signs or the representations made of them, both explicit and implicit norms or rules that learner and feedback sources (community) have to account for and the nature of cooperation or the division of labour between them (Engeström, 2014). Further, the interaction between these factors are both reciprocal and iterative at varying timescales and also depend on the outcomes of feedback seeking. However, in this paper we focus on the interactions occurring at a momentary timescale. Regarding outcomes of feedback seeking, while we acknowledge multiple other outcomes, our focus is specifically on learners' representational sensemaking and their use of representations for thinking, problem solving and communication. To clarify, here the terms 'cost' and 'value' are tied to human nature, where value refers to anything that satisfies a human want and cost is what an individual incurs to satisfy one's want. So cost-value perceptions can be of biological or cultural origins with cognitive, emotion, motivation and identity dimensions (Cropanzano & Mitchell, 2005; Engeström, 2014). Overall, our adaptation accounts for previously discussed issues and helps investigate how the interactions between learner and factors tied to instructional and cultural context impact the development of learner agency towards specific competences. Accordingly, our research questions are: How does the interaction between factors tied to the instructional and cultural context influence learners' cost-value perceptions regarding their different feedback seeking actions? and When and how do learners' feedback seeking actions contribute to the development of their representational competence?

Method

We gave students a representational problem pertaining to the synthesis of an important medicinal drug called 'Warfarin' used to treat blood clots and then examined their feedback seeking actions which emerged during the problem solving. The given problem requires students to employ major forms of representational reasoning like analogical reasoning with representations and thought experimentation or mental simulation with representations (Nersessian, 1999) . Participants have to interpret complex symbolic representations of chemical reaction steps, then determine the spatial arrangement of the intermediate structure formed based on their choice of catalyst and finally predict the expected drug's spatial arrangement by applying stereochemistry concepts. Here the expected medicinal drug's spatial arrangement is most crucial as its therapeutic effectiveness is tied to it. Nature and complexity of the given problem meant that participants would experience numerous challenges nudging them to build molecular models or sketch multi perspective diagrams for exchanging feedback.

We adopt a single case-study approach as it helps us answer the explanatory question of how the interactions between learners and the factors tied to the instructional context influence their feedback seeking actions by providing rich descriptions and insightful explanations. Our case consisted of two male undergraduate chemistry students identified through convenience sampling. They had completed an introductory stereochemistry course. The representational problem was an hour long activity designed such that the participants could either work individually or choose to collaborate as and when needed. This ensured that there was no external compulsion on them to collaborate. Data was collected through video recording of the participants' interaction with each other and the researcher. Data analysis was done using a microgenetic method in which high density observations are made spanning the event's timescale (Chinn & Sherin, 2014). To arrive at the key inferences, we employed competitive argumentation with two other colleagues where a sample data was independently analysed to answer specific questions followed by an open invitation to contest or justify each other's answers. The unit of analysis is an episode of proactive feedback seeking by any participant. By proactive we mean that the decisions such as the timing of feedback seeking and others referred to in the framework were all made by the learners themselves. One episode is distinguished from another by considering the change in the purpose for which the feedback is sought. For identifying instructional factors influencing feedback seeking actions, we examined by going back and forth a few seconds before and after the episode.

Findings

For demonstrating framework's analytical affordances, we present here two feedback seeking episodes. One is Episode-A tied to the analogical reasoning and another is Episode-B tied to the thought experimentation. Episode-A emerged when both participants S1 and S2 were mapping 2D representations of chemical reaction steps with 3D molecular models for arriving at the intermediate structure formed by the catalyst. It started with S1's feedback seeking which appeared as a question to S2. All subsequent conversations within this episode were tied to the S1's initial question. Here feedback occurred as a result of dialogue between S1 and S2 with 14 conversational turns lasting for about 3.33 minutes with an utterance count of 79 and 232 words respectively. On S1's choice of feedback source and timing of feedback seeking when Episode-A started, we observed that it was based on S1's estimate of cost and value associated with sourcing of feedback information from peer or researcher as opposed to generating it by drawing from one's own internal resources and/or working with the available tools and representations. Factors contributing to S1's perceived cost-value estimates were identified by accounting for cognitive, emotion, motivation and identity aspects of participants every moment. For instance, consider the following observations before S1 started seeking feedback.

Alternating one's gaze between the reaction mechanism and the molecular model being held in one hand, S1 utters "*correct, correct"* to oneself and continues with alternation of gaze. After a moment, S1 holds his forehead with the other hand and his facial expression changes from one being calm to one indicating discomfort and difficulty. Then while still looking at the reaction mechanism, S1 asks S2 with a fleeting but embarrassed smile "*DPEN* (catalyst) *what does it do bro?*" without looking up at S2. S2 had started humming a tune while examining the reaction mechanism just a few seconds before S1's question. The researcher was busy sorting worksheets. S2 was also seen picking up models and placing them closer to oneself while uttering "*correct".* Immediately after S1's question, S2 responds with a fleeting smile embodied with a sense of pride.

Above observations suggest that the choice of feedback source and timing of feedback seeking is dependent on both the internal state of S1 and when actually feedback availability cues emerge with the feedback sources in an instructional context. Actions of S2 such as self-directed utterances, humming tune and gestures embodied with emotions cued the feedback availability to S1. Also the likely emotions experienced by S1 due to difficulty in solving the task signalled the high cost in continuing to rely upon self as a source of feedback. S1's embarrassed fleeting smile and S2's fleeting smile embodied with pride shows the influence of prevailing cultural norms where ignorance or lack of competence is often treated with shame whereas showcasing one's competence is encouraged with explicit recognition. Hence for S1, to seek feedback from external sources involved the cost of threat to one's identity as it could reveal one's lack of competence to them. This further depends on the S1's perceived relational and identity aspects shared with the feedback sources. Thus seeking external feedback by incurring such costs, points to S1's motivation towards the learning activity.

Similar to Episode-A, the choice of feedback source and the timing of feedback seeking in Episode-B was preceded by the emergence of feedback availability and non-availability cues. But these cues were much more explicit in the form of their think-aloud. Before Episode-B started, S2 was observed uttering *"I don't know why I need to draw a Newman diagram?".* A few seconds later this was followed by S1's uttering "*Okay now I am understanding what it is*". Immediately S2 approaches S1 and the resulting dialogue lasts for around 16.56 minutes. Thus even when multiple peers are present these actions could occur as a result of cost-value analysis considering both feedback availability and non-availability cues emerging dynamically amongst them.

Further, for Episode-A we traced the emergence of feedback availability and non-availability cues in S2 and S1 respectively to the sequence of their interactions with artefacts such as different molecular models and sketches before and during feedback seeking. We observed that by the time S1 sought feedback, S2 had already referred to different individual molecular models which together constitute the intermediate structure. On the other hand, S1 was seen trying to make sense of the task by referring to just one model tied to intermediate structure. This shows us how subtle differences in interaction with artefacts contribute to the emergence of S1's perceived cost in continuing to rely upon self as a feedback source and S2's perceived value in providing feedback as it adds to both one's self image and problem solving goals. This discussion also holds for how S1's interactions with artefacts influenced the purpose for which he sought feedback. In addition, we observed that throughout feedback seeking, S1 incurs cost in terms of continuously monitoring and judging the feedback received against one's requirement for its relevance, specificity and accuracy. Based on such evaluation S1 seeks further elaboration, clarification while also contesting, verifying and confirming. Anticipation of such costs during the dialogue was observed to influence decisions like whether or not to continue seeking feedback with S2. Also varying time gaps between conversational turns were observed to be crucial for S1 to monitor, judge and construct a response to the feedback received. This was mutually negotiated through monitoring each other's verbal utterings, voice tone, facial expressions and gestures. All these are key features of 'feedback as dialogue' notion by which learners' unique and diverse feedback needs are met.

Regarding the amount of feedback seeking, although at surface it appears to be largely influenced by the complexity of subtasks, the characteristics of feedback source and feedback seeker are equally significant. For instance, the Episode-B which emerged during the subtask requiring mental simulation with representations lasted for about 16.56 minutes with 70 conversational turns in total. This is almost five times larger in terms of time spent and the number of conversational turns than Episode-A which emerged during subtask requiring just analogical reasoning. Here when we examined the nature of reciprocal exchanges between S1 and S2, it became evident that the amount of feedback seeking is equally shaped by the individual characteristics. If S1's perceived proficiency of S2 is low, then cost associated with feedback received like the need to monitor, judge and verify will be high. And actual proficiency of S2 will determine whether or not feedback provided will be justified or the mode of provision will be adapted to persuade the seeker. For instance, initially S2 starts providing feedback by mostly pointing at models or the reaction mechanism but later builds a complex intermediate structure with multiple models to convey one's feedback. It is during the feedback provision that the source comes to realize the cost associated with providing feedback and the value of using multiple representations in conveying one's feedback. An experienced or more proficient feedback source like an instructor might anticipate this much early thus reducing the cost associated with feedback seeking for learners and hence the amount of feedback seeking.

Another key aspect contributing to perceived cost-value estimates of learners and feedback sources regarding their feedback seeking and provision is how they cooperate or negotiate division of labour. For instance, in Episode-A while providing feedback, S2 encounters a situation where division of labour could be of help. Task involves identifying and distinguishing similar looking molecular models while trying to build an intermediate structure. S2 assigns this task to S1 and assignment of this task comes in the form of a question. But S1 redirects the task to S2 as he is holding the model and it is easier to apply chemical naming conventions by holding one. S2 instead goes on to check previous sketches of catalyst without expressing any emotion tied to disappointment or bitterness. Then S1 reassigns the task to himself and rules out that the model is not the one they were looking for. S2 does the same for another model and confirms that model as the required one. Both S1 and S2 based on momentary need, judge whether to allocate, distribute or redirect tasks to each other based on their cost-value estimates of what it requires to perform the task. In Episode-B, such instances were predictably high but they were also fraught with negative emotions such as irritation and frustration. So task complexity means that how participants mutually assign, redirect or reassign specific tasks while being sensitive to each other's emotions and motivation has potential to increase or decrease cost associated with feedback dialogue.

Our examination of factors contributing to the participants' perceived cost-value estimates regarding their modes of feedback seeking and feedback provision revealed the relationship between feedback seeking and the use of multiple representations. Consider the following observation from Episode B. Initially the mode of feedback seeking and the provision involved just the verbal exchange but then the participant seeking feedback did not get convinced with the feedback received. So he kept probing the feedback provider verbally. As a result, the peer providing feedback adapts one's mode of feedback provision. He first uses the model to convey one's feedback and later sketches the 2D diagram to convey the same recognising that the former did not serve the purpose. The participant seeking feedback still not satisfied with the feedback received, builds a model to convey one's reason for not being convinced and then goes on to elicit more feedback. And these transitions were fraught with emotions such as irritation and frustration. This suggests that affordances of specific feedback seeking strategies and representations can vary depending on the contextual factors such as characteristics of learner, feedback sources, available artefacts and specific task elements. Hence it is during the feedback dialogue that learners encounter opportunities to confirm or iteratively revise their cost-value estimates of different feedback seeking strategies and representations for thinking, communicating and problem solving.

Abstract: To support student learning of Computational Thinking (CT) in disciplinary contexts, it is important that teachers have agency and ownership in the design process of creating curricula. We conducted a 4-week-long summer institute for teachers to co-design CT-integrated high school science units. Our approach to CT integration into Science and Mathematics contexts is based on a *taxonomy-of-practices* of CT in Science and Mathematics professional contexts. The co-design teams in our summer institute used a version of this taxonomy to create CT-integrated lessons. In this paper, we analyze two co-designed biology units to characterize CT integration in these lessons using the new taxonomy. The results illustrate various types of activities and questions developed as a way to promote student engagement in CT practices in the disciplinary context. Findings yield implications for CT integration in disciplinary contexts as well as co-design of CT-integrated units based on a *taxonomy-of-practices*.

Keywords: computational thinking, practices, taxonomy, co-design, science education

Introduction

As computing becomes ubiquitous in science, technology, engineering, and mathematics (STEM) fields and society, researchers and educators have argued that it is crucial to build foundational Computational Thinking (CT) and literacy skills in K-12 settings (Wing, 2006; Grover & Pea, 2013; Wilensky et al., 2014). In our work, we integrate computational thinking (CT) into mathematics and core science courses because: (1) Unlike elective computer science courses offered in high school, the integration of CT into science courses ensures all students engage in CT and build computational literacy, addressing issues of underrepresentation and self-selection in computing fields (Wilensky et al., 2014); (2) The integration of CT into science and mathematics can support deeper learning of the science content (e.g., Levy & Wilensky, 2009); (3) With such integration, students can learn authentic disciplinary practices recommended by the Next Generation Science Standards (NGSS) (NGSS Lead States, 2013; Dabholkar et al., 2020).

Inviting teachers to be design partners of new units has increased teacher ownership of curricular changes and supported appropriate pedagogical shifts (Kyza & Georgiou, 2014). In order to design CT-integrated curricular units, we partnered with high school science and mathematics teachers. We conducted a 4-week-long summer institute to co-design units with newly designed computational tools and pedagogical activities to support learning. Our co-design approach foregrounded teachers' views on how the curriculum aligns with learning objectives, teaching strategies, and expectations for student learning (Severance et al., 2016). In this paper, we analyze two co-designed biology units to characterize CT integration in a disciplinary context.

Theoretical framework

Prior work defined a taxonomy of CT practices in the context of science and math that includes modeling and simulation, data, problem solving, and systems thinking practices (Weintrop et al., 2016). Our team has used this *taxonomy-of-practices* to design and co-design CT-integrated science and math units over the past several years, resulting in several important outcomes for student learning (e.g., Arastoopour Irgens et al., 2020) and teacher learning and attitudes (Peel et al., 2020; Wu et al., 2020). Based on our experiences, a new version of the *taxonomy-of-practices* (ToP 2.0) is currently in development that represents a wider set of CT practices that we feel the original taxonomy did not include or did not give enough attention to (Peel et al., 2021). An initial beta version of the new taxonomy was piloted in this project. There are six practice categories in the CT-ToP2.0-beta: *computational modeling and simulation, computational data, computational visualization, algorithms, computational problem-solving,* and *programming*. The CT-ToP2.0-beta was used as a framework to integrate in science and mathematics curricular units. This paper uses the CT-ToP2.0-beta to frame our analysis of two co-designed biology units. The following research question guided the analysis: *How were CT practices integrated into co-designed biology units?*

Research and co-design context

Our team worked with 11 teachers in summer 2020 during a 4-week summer institute. Due to COVID-19 regulations, the summer institute was held remotely. Teachers learned about CT integration and pedagogy by engaging as learners in the first week of the summer institute. The following three weeks were used to co-design new CT-integrated science and math units. Each teacher, or pair of teachers, partnered with a member of the research team to co-design CT-integrated units and computational tools to support student engagement in CT practices and learning of science/math content. Teachers read a Google Slides presentation that introduced them to the CT practices. They were then asked to read a document with descriptions and curricular examples of each practice category.

CT-STEM website and Biology units

The curricular units developed in the summer institute are hosted on a website that facilitates curricular design and use in classrooms (https://ct-stem.northwestern.edu). Each curricular unit consists of several lessons, and each lesson has multiple pages containing questions that prompt student engagement. Lesson pages can include embedded computational tools (Figure 1). For example, Figure 1A shows a computational model embedded in the lesson titled: *How do the instructions to make proteins work?* The students are asked to explore the model and note the observations they find interesting. The follow-up questions on the subsequent pages provide scaffolding to support student learning of specific biological aspects regarding the process of DNA replication and transcription.

A B

Figure 1. A screenshot of embedded computational models in lessons in CT-STEM website

The two co-designed biology units that we analyze in this paper were about the Central Dogma and Covid-19 transmission. The Central Dogma unit, of the lead-co-designer teacher Ms. Kate (pseudonym), has computational activities that engage students in learning about Central Dogma. The second biology unit about Covid-19 transmission, of the lead-co-designer teacher Ms. Sara (pseudonym), is designed for student to use computational models for learning about transmission of COVID-19, focusing on the infectiousness of the virus and behavior of people.

Methods

We created a codebook to code questions in the lessons for taxonomy 2.0-beta categories. It contains the explanations and examples of each code. We coded 272 questions from 16 lessons in the two biology units. If a question prompted students to engage in multiple categories of practices, it was coded positive for all the categories. Author 1, 2, and 3 were involved in coding. Cohen's *Kappa* was used to determine interrater reliability. *Kappa* > 0.75 was considered as a cut-off. To characterize the units in terms of CT practice integration, we calculated percentage integration for each of the practices. To further characterize the how the practices were integrated in the lessons, we calculated the extent of integration (density) and presence of different types of CT practices (variety) for each page. We calculated Density and Variety scores using the following formulas: Density = total number of practice codes / total number of questions; Variety = practice categories coded / total number of practice categories.

Analysis and findings

In this section, we first present analysis of the units in terms of integration of CT practices. Then we discuss a page that has high density and variety of CT practices as an illustrative example of CT integration.

CT practices integration

Computational modeling and simulation practices were most prominently integrated in the lessons (Figure 2). *Computational visualization practices* and *Computational data practices* have more than 10% integration. Though this claim needs to be substantiated on the basis of student responses to the questions, we expect that minimum of 10% integration is needed for each category to provide adequate exposure. We used density and variety scores to identify high CT integration pages, one of which is discussed below to illustrate integration of the CT practices.

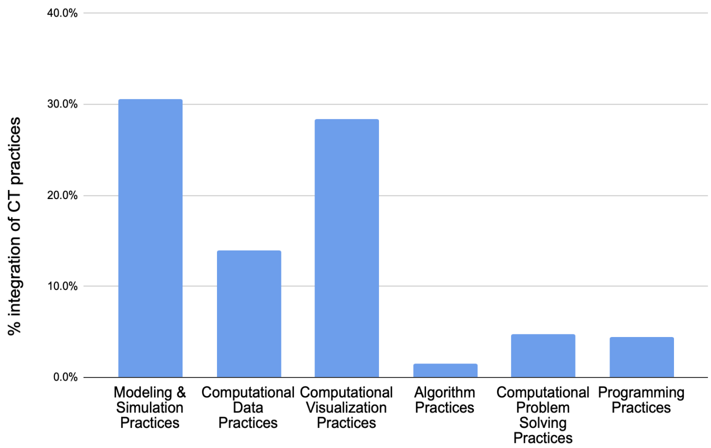

Figure 2. Percentage integration of CT practices in the biology units

An illustrative example of CT integration

We used density and variety metrics to identify pages that have high CT integration. We present qualitative analysis of CT integration in Page 3, 4 and 5 of lesson 5, of the Central Dogma unit (density score > 1 and variety score => 0.5) to illustrate how CT-ToP2.0 -beta practices were integrated. Lesson 5 was designed for students to understand the underlying biological processes that result in differences in hair color. In this lesson, students use a computational model built in NetLogo (Wilensky, 1999) (See Figure 1A). It is a test tube model of DNA replication and transcription. In this model, students can add appropriate 'ingredients' computationally and observe the outcomes. After students were asked to explore the model and make observations, to understand the processes and the functions of various macromolecules (e.g., DNA polymerase). Kate and her team designed these questions for students to use a *computational visualization* of a manipulable process in a scaffolded manner to engage in *computational modeling and simulation*. The model shows percentages of bases on the old DNA strand and the new strand. The questions ask students to make qualitative observations and collect qualitative data regarding the process of DNA replications. On the next page, students are asked to more systematically engage in *computational data practices* by performing trials and collecting data to identify a pattern regarding DNA replication (Chargaff's law).

On page 6, students are asked *to make RNA based on a DNA template.* This requires students to think about how to use a computational tool by providing appropriate inputs to generate a desired output. This requires them to engage in *computational problem solving practices*. This page has a model that has an intentionally placed bug. After students engage in *computational problem solving*, they are asked to identify a bug in the model. They are asked to engage in *programming practices* by modifying the program to fix the bug.

Discussion and implications

Integration of CT practices in disciplinary contexts serves two reciprocal purposes: (1) CT practices can have pedagogical value for learning the disciplinary content; (2) Disciplinary contexts can provide rich ways to engage in CT practices. Different levels of engagement in CT practices in disciplinary contexts can be thought of as a spectrum of sophistication. In disciplinary contexts less sophisticated practices, such as changing model parameters and observing the effects, are of pedagogical value whereas the disciplinary context provides ways for engaging in more sophisticated practices, such as understanding algorithmic logic in a model and modifying it. The example activities discussed in the results section demonstrate the co-design team's intentions of engaging students across the full range of sophistication to support the learning of key disciplinary ideas regarding DNA replication and RNA synthesis and then using the context to engage students in understanding programming and debugging.

The co-design approach for CT integration into these units was predominantly based on co-designing computational models and then using those models to engage in other CT activities. It is possible that the practices more prominently present in the lessons are due to the nature of the computational tool, NetLogo (Wilensky, 1999), that was used for CT integration. NetLogo is a highly effective modeling platform that allows easy creation of computational visualization of phenomena, performing multiple experimental trials and collecting data. In addition, the NetLogo code can be easily accessed, read and manipulated to debug and extend computational models. These affordances of the NetLogo environment open possibilities for integration of the full range of CT practices at all levels of sophistication. However, we anticipate that such wholistic intertwining of CT practices with a model-centered CT integration approach would require more intentionality in the co-design process. Even though new practices such as algorithm and programming practices were not present in high density, the addition of these practices in the taxonomy possibly resulted in the design of activities about understanding and modifying the code and writing algorithms for understanding computational aspects of biological processes. Our other work has demonstrated that sophistication and variety in CT integration can increase through the co-design experience of teachers over a couple of years (Peel et al., 2020). We anticipate more variety and sophistication in future units designed by these teachers.

Abstract: In this article, we introduce a conception of diagnostic argumentation skills and define three relevant facets, namely justification, disconfirmation and transparency. We present initial investigations in the three facets' (co-)occurrences in diagnostic argumentation and their relation with the accuracy of diagnostic decisions in the context of teacher education. For this purpose, we analyze data of 118 pre-service teachers, who were learning with simulated cases concerned with the topic of students' clinical problems. We interpret the results as justification, disconfirmation and transparency being three distinct facets of diagnostic argumentation skills. We also assume that justification may relate to cross-domain transferable argumentation skills, while disconfirmation and transparency are rather context-specific aspects of diagnostic argumentation, relating to standards in diagnosing. Moreover, we discuss the type of reasoning and prior processing of the case as potential explanation for a correlation found between justification in diagnostic argumentation and the accuracy of diagnostic decisions.

Pre-service teachers' diagnostic argumentation and diagnostic accuracy

Skills of diagnostic reasoning and argumentation are relevant in many disciplines (Heitzmann et al., 2019). In this article, we outline a conception of diagnostic argumentation skills and define three relevant facets, namely justification, disconfirmation and transparency. Furthermore, we present initial empirical investigations concerning their (co-)occurrences in diagnostic argumentation and their relation with the accuracy of diagnostic decisions in the context of teacher education.

The learning of diagnostic skills is a matter of professionalization within various disciplines (Heitzmann et al., 2019). Beyond medicine and medical education, also other disciplines like teacher education emphasize the role of diagnosing as "a process of goal-oriented collection and integration of case-specific information [aiming] to reduce uncertainty in order to make […] decisions", but use other terminology like *assessment* (Heitzmann et al., 2019, p. 4). Teachers need to diagnose students' performance, progress, and among other learning prerequisites, initially identify learning difficulties such as dyslexia or even behavioral disorders like ADHD (Praetorius et al., 2013; Reinke et al., 2011). Indeed, higher education programs in teaching and other disciplines increasingly acknowledge the relevance of diagnostic skills (Heitzmann et al., 2019). Simultaneously, research places a stronger emphasis on the facilitation of diagnostic skills, e.g., by exploring the effects of simulation-based learning on facilitating diagnostic skills (Chernikova et al., 2019). Advancing the understanding of the nature and relation of diagnostic skills is an essential foundation for learning and researching diagnostic skills.

Diagnostic skills reflect the application of professional diagnostic knowledge, e.g., in terms of effective diagnostic action and accurate diagnostic decisions (Heitzmann et al., 2019). Effective diagnostic action is researched e.g., in terms of epistemic activities like generating hypotheses, generating and evaluating evidence, and drawing conclusions (Fischer et al., 2014). However, research and education generally refer to the accuracy of diagnostic decisions as main indicator of diagnostic skills (e.g., Praetorius et al., 2013). The literature suggests that reasoning processes, which are underlying diagnostic action and diagnostic decision-making, can be either of fast and intuitive or of slow and reflective nature (Mercier & Heintz, 2013). While reflective inferences are conscious and explicable, intuitive inferences are less accessible for explication (Mercier & Heintz, 2013). Nonetheless, communicating diagnostic considerations, activities and decisions is crucial in various situations like collaborative diagnosing or verbalized post-hoc argumentation, e.g., when writing a report. In such situations, diagnostic reasoning is ideally explicated in the form of coherently interrelated arguments (Walton, 1990). We broadly subsume such instances of interrelated diagnostic arguments as *diagnostic argumentation*. Moreover, we assume that diagnostic argumentation does pursue different epistemic aims: Diagnostic argumentation may for example aim for sense-making during diagnostic action as well as for articulating or persuasively presenting diagnostic decisions (Berland & Reiser, 2008; Chinn, Rinehart, & Buckland, 2014). So far, research investigating verbal outcomes in diagnosing mostly focused on justificatory accuracy, e.g., in verbalized sense-making during the diagnostic process (e.g., Braun et al., 2018) or in articulating diagnostic decisions (e.g., Praetorius et al., 2013).

In our research, we build on the broader literature on scientific argumentation, which pointed out that beyond accuracy there are other, especially structural features contributing to an argumentation's persuasiveness (e.g., Hitchcock, 2005). It is not clear however, if structural features of diagnostic argumentation necessarily correlate with the accuracy of diagnostic decisions or if they reflect distinct diagnostic skills. Qualitative findings indicated that formal aspects of presenting arguments about diagnostic decisions may not necessarily correlate with accurate diagnostic decisions; instead, structural features of diagnostic argumentation may rather depend on additional skills (Braun et al., 2018), like cross-domain argumentation skills (Hetmanek et al., 2018). In addition, diagnostic argumentation may be a matter of internalized standards that are specific to the context of diagnosing (Bauer et al., 2020; Chinn, Rinehart, & Buckland, 2014). We conclude that further research is needed to investigate the nature of diagnostic argumentation and its distinction from other diagnostic skills, particularly accurate diagnostic decision-making. For this purpose, we outline a conception of diagnostic argumentation skills in the following and define three relevant facets, namely justification, disconfirmation and transparency.

The majority of studies considering argumentation structure refer to Toulmin´s argumentation scheme (2003). This model especially highlights the role of *justification*, since any claim requires some grounding to build a complete argument. Transferred to the context of diagnostic argumentation, diagnoses are comparable to claims that need to be justified with evidence. Moreover, the Toulmin scheme (2003) emphasizes the role of rebutting counterarguments and competing claims in supporting an overall conclusion. This rationale functionally resembles the scientific approach of *disconfirmation*: In the case of two competing hypotheses, a finding of evidence disconfirming one hypothesis supports in turn the other hypothesis. Disconfirmation is particularly relevant in cases that involve uncertainty, e.g., due to an incomplete data basis, thus requiring probabilistic reasoning (Kind & Osborne, 2017). Simultaneously, rejecting relevant differential diagnoses supports the plausibility of a diagnostic conclusion, especially in diagnosing cases that involve ambiguous evidence. Furthermore, elaborating on scientific argumentation and standards in science, other major themes are the reliability of processes and the evaluation of evidence in reference to methodology and data sources (Chinn, Rinehart, & Buckland, 2014; Fischer et al., 2014). Accordingly, *transparency* with respect to the processes is considered essential in underlining the quality of the presented evidence and conclusions (Vazire, 2017). In diagnostic argumentation, this is achieved by describing the processes undertaken to generate evidence.

We assume that justification, disconfirmation and transparency are three relevant facets of diagnostic argumentation. It is not clear however, if they are correlated, reflecting an overall diagnostic argumentation skill, or if they are distinct diagnostic argumentation skills. Therefore, to approach this issue, we explore how justification, disconfirmation and transparency (co-)occur in diagnostic argumentation (RQ1). Moreover, referring to the question of distinguishing diagnostic argumentation from diagnostic decision-making, we investigate, how justification, disconfirmation and transparency in diagnostic argumentation relate to diagnostic accuracy (RQ2).

Methods

We recruited 118 pre-service teachers to participate in a study that evaluated a simulation-based learning environment concerned with the topic of students' clinical problems that we developed for a teacher education program. The participants processed eight simulated cases of primary and secondary students displaying behavior that might indicate a disorder in the spectrum of either ADHD or dyslexia. Doing so, they could access several informational sources such as samples of the student's written exercises and school certificates, reports of observations from inside and outside of the classroom, conversations with the respective student, the parents, and other teachers. Participants had two tasks per case: (A) they had to make a diagnosis by indicating whether the simulated student might have a clinical problem and if so, which one it might be; (B) we asked the participants to write an argumentation about their conclusion and their approach in reasoning about the case. The data collection was computer-based and took place in a laboratory setting. We introduced participants to the aims and procedure of the study and familiarized them with the simulation-based learning environment. After giving informed consent to participate in the study, they answered a pretest that took around 35 minutes. Afterwards they entered the learning phase, consisting of the eight simulated cases. Time on task for all cases was M = 51.8 minutes (SD = 16.5). After four cases, participants took a break of ten minutes before continuing with solving cases five to eight. Subsequently, they answered a posttest, which took again around 35 minutes.

The data sources used for the analyses presented in this paper are the diagnoses (A) and the diagnostic argumentations (B) from six of the eight cases. We coded diagnostic accuracy of all the written diagnoses (A) as accurate (1 point), partially accurate (0.5 point) or inaccurate (0 points). Two raters coded 12.5% of the diagnoses, resulting in an inter-rater reliability of Cohen's κ = .80. The internal consistency across the six cases was rather low (McDonald's ω = .37). For further analyses, we calculated a sum score of the points achieved in terms of diagnostic accuracy with a possible range from 0 to 6 points.

Afterwards, we coded diagnostic argumentations (B) in two independent rounds of coding. First, we segmented and coded all argumentations in terms of the four epistemic activities *generating hypotheses, generating evidence, evaluating evidence* and *drawing conclusions*. Four raters coded 15% of the data in parallel before dividing the rest of the data. Subsequent to the initial coding, we decided to include *generating hypotheses* into *drawing conclusions*, resulting in a merged category of *drawing conclusions* (Krippendorff's $a_U = .62$) and the two additional coding categories *generating evidence* (Krippendorff's $a_U = .56$) and *evaluating evidence* (Krippendorff's $a_U = .75$). In a second round, we coded the diagnostic argumentations of six cases regarding the content dimension of *differential diagnoses*. 15% was double coded resulting in an overall inter-rater reliability of Cohen's $\kappa = .92$. We operationalized *justification* in diagnostic argumentation as one or more co-occurrences of evaluating evidence and drawing conclusions within a temporal context of two sentences. Moreover, we considered *disconfirmation* in diagnostic argumentation to apply if the argumentation included at least two differential diagnoses. Thirdly, we defined *transparency* in diagnostic argumentation as at least one explication of generating evidence. Internal consistencies across six cases was satisfactory, with McDonald's $\omega = .60$ for justification, McDonald's $\omega = .60$ for disconfirmation, and McDonald's $\omega = .71$ for transparency. For all three variables, we calculated again sum scores with a possible range from 0 to 6 points.

To explore both research questions, we used Pearson's correlation analysis, including the variables justification, disconfirmation, transparency, and diagnostic accuracy. The alpha level was defined as $\alpha = .05$.

Results

To explore, how justification, disconfirmation and transparency (co-)occur in diagnostic argumentation (RQ1), we report descriptive results and a Pearson correlation analysis. Across the six cases, participants put most emphasis on justification, which we found on average in around two thirds of their diagnostic argumentations ($M = 3.83$; $SD = 1.58$). Moreover, we found that participants hardly applied disconfirmation, which only occurred in around a quarter of the diagnostic argumentations ($M = 1.52$; $SD = 1.41$). We found transparency in around half of the diagnostic argumentations ($M = 2.67$; $SD = 1.81$), which is considerably less frequent than justification but more frequent than disconfirmation. Pearson correlation analysis indicated that justification and disconfirmation may be related, since the correlation was significant with a large effect ($r = .568$, $p < .01$). In contrast, transparency was not significantly correlated with justification ($r = .055$, $p = .55$) or disconfirmation ($r = .025$, $p = .79$).

To investigate, how justification, disconfirmation and transparency in diagnostic argumentation relate to diagnostic accuracy (RQ2), we report again a Pearson correlation analysis. Participants' average diagnostic accuracy was $M = 4.41$ (maximum of 6 achievable points; $SD = .94$). We found diagnostic accuracy and justification to correlate significantly, with a small effect ($r = .284$, $p < .01$). However, there were no significant correlations between diagnostic accuracy and disconfirmation ($r = .105$, $p = .26$) as well as transparency ($r = .059$, $p = .53$), indicating that diagnostic accuracy discriminated between justification and disconfirmation.

Discussion

Exploring the (co-)occurrences of justification, disconfirmation and transparency in diagnostic argumentation (RQ1), we found that pre-service teachers rather applied justification in their diagnostic argumentations than disconfirmation and transparency. Since there was no specific instruction that prompted students to emphasize justification in particular, we interpret that justification is less specific to the context of diagnosing, but may relate to a more generalizable skill level like cross-domain transferable argumentation skills (Hetmanek et al., 2018). Compared to justification, especially disconfirmation but also transparency were less prevalent in diagnostic argumentations. We suggest considering them as more specific argumentation skills (Hetmanek et al., 2018) that relate to standards in diagnosing or even broader standards of science (Chinn, Rinehart, & Buckland, 2014). Previous research has issued that such diagnostic standards may be insufficiently taught in teacher education (Bauer et al., 2020). Moreover, despite the finding of justification correlating highly with disconfirmation, we also found that diagnostic accuracy correlated only with justification but not with disconfirmation, thus discriminating between the two facets. Overall, we interpret that justification, disconfirmation and transparency seem to be rather independent diagnostic argumentation skills. In contrast to disconfirmation and transparency, justification significantly correlated with diagnostic accuracy (RQ2). Since the effect was only small, we still consider justification in diagnostic argumentation and the accuracy in diagnostic decision-making as two different skills. We assume that the correlation may be explained by reflective inferences made during the prior processing of the case (Mercier & Heintz, 2013): Reflective inferences are a conscious and explicable type of reasoning, which may facilitate both justification in diagnostic argumentation and accuracy in diagnostic decision-making.

Some methodological remarks seem relevant for our interpretation: Inter-rater reliabilities of generating evidence and drawing conclusions are rather low. However, the initial coding reflects the simultaneous segmentation and coding of individual epistemic activities; hence, we consider the agreement as sufficient for the combined task. Moreover, for our operationalization, we did not use the initially coded individual epistemic activities, but abstracted their overall presence or absence, on the level of diagnostic argumentations. Thus, we suppose that the actual agreement on the analyzed level of diagnostic argumentations is most likely superior to the agreement presented. A second limitation consists in the low internal consistency of diagnostic accuracy. This issue is in line with other studies suggesting that the accuracy of diagnostic-decision-making is comparably content-specific and thus, internal consistency of diagnostic accuracy only increases across a large number of cases (Monteiro et al., 2020).

Based on our initial considerations and results presented in this paper, we suggest that justification, disconfirmation and transparency represent three distinct facets of diagnostic argumentation skills. We derive the assumption that justification relates to cross-domain transferable argumentation skills, while disconfirmation and transparency are rather context-specific aspects of diagnostic argumentation. We also assume that reflective inferences made during the processing of the case may facilitate both justification in diagnostic argumentation and accuracy in diagnostic decision-making. Justification in diagnostic argumentation and accuracy of diagnostic decision-making seem to be distinct outcomes, reflecting different diagnostic skills. Therefore, as a matter of further professionalization, research and learning programs interested in diagnosing may consider diagnostic argumentation skills as relevant outcomes and distinguish them from established indicators for diagnostic skills, like accurate diagnostic decisions.

Former Students' Perspectives on the Value of Computing Education Programs

Melissa Perez, Patricia Garcia, Barbara Ericson
perezme@umich.edu, garciapg@umich.edu, barbarer@umich.edu
University of Michigan, School of Information

Abstract: One of the major efforts in computing education research is to broaden participation, especially involving women and people of color. This work presents the perspectives of women of color who participated in programs that were meant to encourage them to engage with computing, to understand what they valued. These insights could inform the design of future computing education programs.

Introduction

As broadening participation in computing (BPC) movements across the U.S. strive to democratize computing education, it is important to make explicit the values embedded in computing programs and to examine their impacts on learners, especially those from underrepresented backgrounds in computing (Santo, et al, 2015). Computing education programs highly value continued participation and persistence in computing, which tends to focus on students' reported career interest (Weidler-Lewis, et al, 2017). However, existing research argues that disciplinary views of participation and persistence are narrow and overlook the positive impacts on learners who may not choose to participate in computing in formalized ways, such as pursuing a computing major or career (Weidler-Lewis, et al, 2017). In this work, we examine participation and persistence in computing as a form of *social practice*; we investigate how BPC program participants make meaning out of their computing education experiences in ways that extend beyond formalized academic and career pursuits. In particular, we analyze how former BPC program participants articulate the perceived value of their participation and how they continue to apply the knowledge and skills they gained to different aspects of their lives.

We used photo elicitation interviews with a series of prompts designed to address the following research question: *How do former participants of BPC programs perceive the value of their experiences?* We conducted interviews with 12 women who participated in BPC programs in high school. Our data analysis was theoretically informed by the concept of "figured worlds," defined as "... a socially and culturally constructed realm of interpretation in which particular characters and *actors* are recognized, significance is assigned to certain *acts*, and particular *outcomes* are valued over others" (Holland et al., pg 52, 1998, emphasis added). Our findings show that while half of the participants did not pursue degrees or careers in computing, the programs did have lasting impacts on the significance they assigned to computing, including viewing computing as an avenue for personal development, relationship-building, and helping others. To illustrate this, we draw on the stories of three participants and detail their personal reflections on the programs they were involved in.

Background: Broadening participation in computing

Despite efforts to broaden participation in computing, disparities in participation among underrepresented minorities continue to persist across all educational levels (Code.org, et al, 2020). Scholars have examined numerous factors that contribute to these disparities, including the detrimental impact of racialized and gendered stereotypes (Margolis & Fisher, 2002) on learner interest and unequal access to rigorous CS education opportunities (Margolis, et al., 2017). In an effort to address these disparities, researchers advocate for early exposure to computing and propose programmatic efforts at the primary and secondary level that provide opportunities for students from underrepresented backgrounds to gain computing skills. However, despite an increase in available BPC programs, the upstream effects of these efforts have been slow and particular groups, such as women of color, continue to be vastly underrepresented in computing careers (Code.org, et al, 2020). While we acknowledge the importance of continuing to work toward increasing the number of underrepresented minorities in computing careers, we also urge researchers and educators to broaden their understanding of *what it means to participate* in computing. We present a more expansive view of participation and persistence in computing that is grounded in how former BPC program participants reflect and make meaning of their computing education experiences.

Conceptual framework: Figured worlds

We employ "figured worlds" to understand multiple aspects of participants' experiences. A *figured world* consists of actors who perform acts, with values ascribed to certain outcomes of participation. The "roles" that are played by participants in a figured world are not necessarily static, such as a student/teacher role, rather are "figured" by participants as they interact with one another over time (Urrieta, 2007). Understanding the actors, acts, and outcomes that are valued and reproduced within a figured world of computing created by BPC programs could be important for informing how value is placed on actors, acts, and outcomes within the dominant or broader figured worlds of computing (Perez, 2020). Drawing attention to how the aspects of the physical environment play a role in figured worlds (Hdlaik, et al, 2020; Sengupta & Shanahan, 2017), the photo elicitation method was chosen so participants can (re)present acts, actors, and outcomes of their figured worlds of computing.

Methods

We conducted photo elicitation interviews where participants were asked to bring photos (original or found) that (re)presented aspects of their "figured world" of computing, such as actors ("Who participates in computing?") and practices ("What do people who participate in computing do?"). In total there are 12, hour-long, semi-structured photo-elicitation interviews with women from different BPC programs (Table 1). Interviews were conducted virtually and were recorded with the consent of the participants. Future work in this area will include analyzing the photos in combination with the interview transcripts to more holistically analyze their figured worlds of computing and how that might inform future design of computing learning environments.

Table 1: Program information

Program	# participants interviewed	Program Location	Participant Demographics	Program Details
A	7	Texas	Asian: 1; White: 2; Latina: 2; White/Asian/Middle Eastern/North African: 1; Undisclosed: 1	5 days a week/7 weeks over the summer; taught Scratch, HTML/CSS, Python
B	3	Georgia	Black: 1; Black/Latina: 1; White/Asian/Native American/Pacitic Islander: 1	1 week over the summer, weekly during school year; taught Java, Alice
C	2	Arizona	Latina: 1; Undisclosed: 1	Weekly over the school year; taught Scratch, Computer Literacy

The initial open coding of the interviews employed a holistic coding scheme (Saldaña, 2009) which is consistent with a constructivist grounded approach to analyzing data (Charmaz, 2017). The analysis generated 46 child codes that were grouped thematically into 8 larger themes. For the purposes of this paper, we focus on reporting the analysis of codes that exemplify overall themes related to the social aspects of the learning environment.

Analysis

Personal development: Becoming a leader in the program

Miranda is a Latina who participated in Program C in 2009, following a short advertisement about the program in her math class. She and her friend both signed up as something to do and she described participating in the program as an accident, and that she was not planning on going to college when she first enrolled. Despite framing her participation as an accident, she ended up participating as a student for 2 years and as an assistant for the program for 2 more years while in college. She is currently an elementary English teacher. However, when reflecting on the program, she describes how she leads professional development sessions for other teachers on using technology in the classroom, creates videos, and integrates Scratch into her English curriculum, all choices or activities she credits to her participation in Program C during high school.

Her active role as a trainer for other teachers and view of herself as someone who is capable of experimenting with visual programming in the classroom aligns with the description of herself as a "leader" in the program. When reflecting on her role in the program, Miranda said, “We would all help each other... but also it was different in the sense that maybe I started just feeling more of a leader. I was more outspoken. I was presenting more or volunteering to present more.” Within a figured world, learners “figure” who they are through the activities they perform and through social relationships with others (Urrieta, 2007). The role that Miranda played was not fixed; she became “more outspoken” and volunteered to “present more.” Thus, through her increased participation, Miranda begins to see herself in a “different” light, as someone who is capable of leading and making significant contributions. She was able to develop leadership skills based on the way that the program allowed her to show her expertise and help others.

The leadership skills she developed in the program persisted into her career and she continues to grow and share her expertise on using technology in the classroom. Yet, these forms of participation and persistence can be overlooked when focusing on just an interest in a computing career. People engaged in teaching computing or using computational tools can count as part of the wider computing community, depending on how it “is defined and by whom” (Weidler-Lewis et al., 2017).

Relationship building: Making friends

Angelica is a Latina who participated in Program B in 2017. She is currently a third-year undergraduate student who recently switched majors from computer science (CS) to business. In her reflections, Angelica identified making friends and bonding over the experience of learning to program together as important outcomes of her participation. She described being drawn to computing education programs in high school because she viewed them as places where she was able to meet up with friends and develop new connections. The connections she made while participating in Program B were instrumental in her transition to college life: “I'm still friends with [friends from program], we all go to [university], so we still [hang out]. Less last year, but especially freshman year, we would get meals together and hang out. I think most of us were all engineering at that point, but I would be able to study together and just make those connections that I definitely wouldn't have had otherwise.”

The relationships she built through her participation in computing outlasted her decision to major in CS. Although she decided to change majors, she describes still valuing the opportunity to make friends and try out computing: “deep down I always kind of knew it really wasn't the thing for me, but I also just wanted to try it out. Because that's kind of badass…” Given her social nature, part of why the CS major did not resonate with Angelica was how little it showed the opportunity to interact with others as part of a possible career.

In a figured world, learners will attach significance to some acts and not others. Although Angelica was learning to program (which is a key academic outcome), she attached more significance to developing friendships. In her figured world of computing, the social acts of making "new connections" and "study[ing] together" were program outcomes that she personally valued. Importantly, the social outcomes were carried on beyond the program and into her broader educational experiences in college.

Helping others: Teaching with empathy

Deidre is a Black woman who participated in Program C in 2016. She is a fourth year student majoring in CS. Deidre’s experience in the program inspired her to not only pursue CS, but also to come back to the program as a mentor. She describes her decision to mentor other students as motivated by “being in a position to help someone else.” After majoring in CS for a year, she described understanding that there are computing concepts that others can get “caught up on” or struggle to understand. She expressed a desire to “help someone else through it” and to offer words of encouragement such as, "I know it feels this way right now. I felt that way a couple of months ago. But we can sort of work through it." Mentoring served a dual purpose for Deidre; she was able to identify her own knowledge gaps by “reflect[ing] on the things you still don’t understand,” as well as help others who were struggling to learn computing concepts.

As learners construct figured worlds through interactional experiences, they assign significance to particular acts or practices (Urrieta, 2007). BPC programs may narrowly assign significance to computing by primarily focusing on the field as an economically valuable career pathway. Yet, prior research identifies honoring and integrating communal values as crucial to promoting a sense of belonging among students underrepresented in computing (Lewis et al, 2017). Deidre’s reflections reveal that computing had *social* significance that aligned with her values of community-building and “being able to help someone else” with empathy and encouragement. The ability to go back and be a mentor for the program that supported her own educational trajectory in computing aligned with her values and was a personally meaningful outcome of her participation.

Conclusion

The narratives shared by women of color in this study suggest that they valued the social outcomes of participating in a BPC program, including viewing computing as an avenue for personal development, an opportunity to build lasting relationships with others, and a chance to help teach others with patience and empathy. The participants constructed a figured world of computing where social relations and interpersonal interactions were an integral aspect of what it meant to participate and persist in computing. Importantly, all of the participants in this study learned to code, but how they articulated the perceived value of their participation went beyond the mastery of computing knowledge and skills and was equally important to their experience. They viewed other participants as significant actors in the learning environment, valued the relationship-building opportunities presented in the process of struggling and learning together, and assigned communal significance to computing in ways that were closely related to helping others.

What could this mean for BPC programs, specifically those that seek to engage participants from groups that are underrepresented in computing? One thing to consider is how to move beyond an evaluative emphasis on students' interest in a computing degree or career after participation. Based on our findings, even those that did not pursue a computing degree or career still gained lasting experiences that influenced their careers and relationships. Our findings suggest that a more expansive understanding of participation and persistence in computing should include a consideration of learners' personal development and their ability or willingness to engage others in computing, at the very least. Secondly, when designing programs we could aim to create spaces that highlight multiple pathways for participating in computing, including using computational tools in non-computing careers, mentoring and teaching others to code, pursuing computing as a form of enjoyment and hobby, and using computational tools to serve communities and promote social justice.

Examining How Youth Build Comparative Models in Storytelling with Large, Complex Data and Visualization Tools

Jennifer B. Kahn, University of Miami, jkahnthorne@miami.edu
Shyiyan Jiang, North Carolina State University, sjiang24@ncsu.edu

Abstract: While building comparisons is a common data science practice, youth's comparative logic in storytelling with large data and visualization tools has yet to be fully investigated. We present two cases of comparative modeling with socioeconomic data, one where youth constructed a story about a community that suffered a historic flood and another in which youth told stories about personal family migration histories. Our analysis revealed similar and different ways of youth engaging in counterfactual reasoning in their comparisons. Students in the flood project compared actual and imagined economic data trends to show how a particular community fared after the flood, and the student in the family migration project compared actual data trends across cities to consider an imagined personal experience (how she might have grown up). We discuss how youth approached differences in their comparisons in order to connect to local or personal experiences and critique distributions of power.

Introduction

In this paper, we closely examine how youth build comparisons for storytelling with large, complex data and visualization tools. Storytelling with data is a data science activity that is increasingly common across disciplines and industries and has become a necessary critical data literacy practice for democratic participation. Likewise, learning to build models for telling explanatory stories about social and scientific issues is important for youth to learn as well. While establishing comparisons is a central aspect of storytelling and modeling with data, it has not been the focus of recent data science education studies. We seek to understand how youth approach comparisons in their stories in order to support the construction of sound models with unwieldy data, the development of insights from these data and visualizations, and appropriate fit between their models and their stories.

Accordingly, we present a case study comparison that unpacks the nature of youth's comparative modeling with data visualization tools in two different contexts, one in which youth explored their family migration histories and the other in which youth told the story of a community that was severely impacted by a devastating flood. We describe the youth's comparative logic and practices in storytelling with dynamic data visualization tools across cases by analyzing how they leveraged the dynamic data visualization tools to tell their story as well as the temporal and spatial dimensions of the comparisons they established. We conclude with a discussion of how our findings contribute to future learning designs, including how to scaffold learners in building comparative models and facilitate learners' connections to the data through rich, meaningful storytelling contexts.

Theoretical framework

We take an approach to youth storytelling with data that closely aligns with earlier studies of spatial analysis and modeling by both STEM professionals (e.g., Hall et al., 2010) and youth (e.g., Hall et al., 2014) in the Learning Sciences. We view learning as changes in knowledge and action that results in shifts in understanding and participation in the activity (Lave, 1996). This approach considers how individuals coordinate tools and resources for sensemaking in order to develop disciplinary knowledge and understanding of spatial and data representations. Our work also draws on recent studies of how individuals utilize data visualization tools for community storytelling in CSCL and Learning Sciences (e.g., Wilkerson & Laina, 2019; Pfannuch et al., 2010; Radinsky, 2020; Van Wart et al., 2020). These studies identify comparative reasoning as an important activity for storytelling with data and for learning to model aggregate data more generally. Collectively, these works offer insight into the comparative practices of building stories with data: (a) Participants typically established comparisons between two data points or datasets or between data trends and personal experience; (b) participants struggled with making fair comparisons because of sampling and measurement challenges; and (c) comparisons emphasize differences across entities rather than similarities or associations (e.g., covariation) in the data patterns. These studies also highlight the complex relations between data, context, and uncertainty (Wilkerson & Laina, 2019; Rubin, 2020) that data modelers and storytellers need to navigate. However, this research has not deeply explored the dimensions of comparisons and their explanatory value for students' storytelling activities.

Methods

Just as comparative case studies of professionals at work (Hall et al., 2010) have been used to find new insights into how individuals learn to engage in spatial analysis and modeling, we similarly selected case studies to illuminate how youth build comparisons that serve as the basis for their stories. The first case study (introduced in Kahn et al., 2016) comes from a 2-week residential summer human geography course for rising ninth and 10th graders at a private university. As part of the class's culminating project to produce an "untold" placed-based digital story (Hall et al., 2020), one group of four teenage youth told the story of a community's particularly difficult recovery after a flood. The students compared neighborhoods, which differed in racial demographic and socioeconomic status, using US census data in Social Explorer and connected the data to oral histories and artifacts from local library archives as well as multimedia (i.e., recordings of students' field trip visits to parts of the city that were flooded). The second case (introduced in Kahn, 2020) comes from a 2-day workshop in a city public library in which middle and high school youth told stories about personal family migration histories using demographic and socioeconomic data that could speak to larger trends driving migration. In this case, an 11-year-old girl told the story of why her parents moved from Brooklyn to Greenville, comparing the two cities on various indicators with Social Explorer maps. All activities in both cases (the program and workshop) were video recorded.

We selected these two cases because (a) the stories told with data both involved a series of comparative models situated in a compelling storytelling context; (b) both cases presented comparisons that relied on counterfactual reasoning, a form of conditional reasoning in which one imagines "how the world would have been" if an antecedent condition or event happened, even though it did not actually occur (Lewis, 1973); and (c) they used the same dynamic data visualization tool, Social Explorer. Social Explorer accesses hundreds of open demographic and socioeconomic datasets from 1750 onwards and permits users to juxtapose places across the same time or different times in multiple visual ways (i.e., a single data map using a time slider, side-by-side map comparisons). We compared these two cases using interaction analysis methods (Jordan & Henderson, 1995) of video records to analyze participants' discourse and tool use in building and presenting their comparisons. We also examined their artifacts (data map comparisons made in Social Explorer with accompanying text in slides). The current analysis focused on final presentations. We looked for similarities and differences across students' presented comparisons.

Findings

Across the two cases, we found that students built comparisons that organized time and space in complex ways and engaged in reasoning about differences about socioeconomic conditions that the comparisons showed. For both cases, the presentation of stories with data involved counterfactual reasoning. Below we present each case by highlighting key patterns and differences that emerged.

Case study 1: Actual and imagined data trends over time and across communities

Darla, Brayden, Lydia, and David (all participant and city names are pseudonyms) examined imagined and actual data trends over time and across multiple geographic scales to create comparative models and reason about factors that could contribute to the differences they found. In their presentation, the group began by describing a picture of the city's downtown district during the flood, which occurred in 2010. Then they pulled up a swipe map using the time slider that zoomed into the county revealing variation across census tracts, which they used to represent city neighborhoods (Figure 1). The left side of the slider showed the population of *Age 18-64 for whom poverty status is determined (living in poverty)* in 2009 and the right side represented the same indicator in 2011. The students moved the slider back and forth to demonstrate that poverty increased in the county in 2011, after the flood.

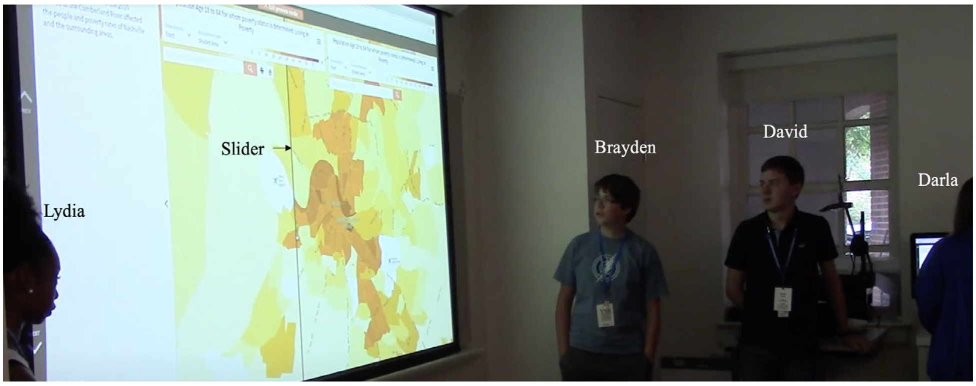

Figure 1. Darla explained the map by dragging the slider. The model compared poverty rates in 2009 and 2011.

Darla: And one thing we thought of was that maybe it's just a coincidence that this happened. So we checked around (*zooming out, first to a regional scale*) in some other places, to see if it affected them too...but---yeah pretty much everything stayed the same (*moving time slider left and right*) except for the areas affected by the flood (*points to an orange area on the screen*)

Then, Darla zoomed out to a regional and national level, shifting the slider back and forth, to show that this economic shift was only experienced locally. They were employing counterfactual reasoning here. If the increase in poverty rates was not unusual, they expected to see it in many other states. Zooming out served to highlight (Goodwin, 1994) comparisons that the students used to rule out other rival (Yin, 2000) causal explanations.

Subsequently, students zoomed into a neighborhood comparison (one predominantly white, more affluent; the other predominantly African American, less affluent) by showing bar graphs displaying small changes in unemployment and poverty in 2009 and 2011 overlaid on the map. Poverty increased in the year after the flood for the more affluent neighborhood (from 4% to 10%) but remained unchanged and high for the less affluent neighborhood (from 10% to 11%). The group pointed out that two neighborhoods did not start from the same place prior to the flood in terms of unemployment and poverty. They then explained that while both neighborhoods faced significant damage from the flood, the less affluent, African American community received less news media attention and consequently fewer allocated resources from the city. The series of comparisons the students presented collectively explained and supported this critique of the distribution of power and access to resources in the city.

Case study 2: Actual data trends across cities to imagine personal experience

In her final data story, Camille described how her family moved from Atlanta to New York for better job opportunities and then to Greenville, where she was born, for a variety of reasons: the New York Blackout of 2003, safety concerns, and lifestyle preferences. Camille built a series of Social Explorer side-by-side map comparisons, selecting the indicator *Total violent and property crimes* (in 2010) to represent safety concerns and the indicators *Owner-occupied housing units: less than $500k* (in 2006), *Workers 16 years and over: car, truck, or van* (in2006), and *Workers 16 years and over: public transportation* (in 2006) to represent "lifestyle." Her comparisons of county level data showed that Brooklyn had lower crime, a higher percentage of houses worth less than $500k, a higher percentage of people using private transportation, and a lower percentage of people using public transportation compared with Greenville. Camille used the datasets from the years after her family moved and she was born to build the counterfactual narrative of what her life would be like if they stayed in New York. As she explained in the narrative, "If my parents had stayed in New York, I would have had to take public transportation, and we probably wouldn't have had a house like we have now because it would cost too much to own a house in New York." With actual data trends across cities, Camille considered how she might have grown up as compared to her current lived experience (i.e., getting around town by car and living in a house as opposed to renting an apartment).

Discussion and conclusion

In these two cases, the "what would have happened" logic of the counterfactual was powerful for students to connect to personal or community experiences. We view the counterfactual as a humanistic, empathetic, and situated approach to the data (Wilkerson & Polman, 2020). However, youth need to be supported in systematically considering other variables that could drive the changes they see. Educators should also ensure that students build reasonable comparisons with georeferenced data, which may entail comparing places at the same geographic scale and/or understanding their scale choices (e.g., the flood group used a national scale [US states] to rule out causal explanations and looked across census tracts [neighborhood scale] to reason about differences in poverty rates). There may also need to be discussions of how to interpret singular data points from large, aggregated data, which are typically averages for a geographic area in choropleth maps, or how to analyze a trend across multiple data points.

Notably, students in both cases tried to highlight and reason about differences between communities but in different ways. The flood group focused on economic change over time in two communities in order to tell the story of one community's unjust treatment in the aftermath of the flood, which they had initially learned about from other contextual sources (i.e., library archives). Camille tried to understand differences between two cities in order to imagine how her day-to-day experiences might have been different. In both cases, youth tried to reason about differences in the data at the level of lived experience, whether their own lived experiences or that of others that had been shared with them. Furthermore, while we found that youth were more interested in telling stories about bigger differences, which aligns with other studies of youth data modeling, when they focused on smaller differences, they were able to add critical nuance to support their story (i.e., the flood group noted the small change in one neighborhood's poverty rate was related to its pre-flood poverty rate). We suggest that students may need more encouragement from instructors to consider similarities and smaller differences, which would include looking for patterns and arranging/connecting multiple comparisons in a meaningful way for effective storytelling. Moreover, students' use of spatial counterfactuals demonstrated that they were capable of learning and interested in participating in these complex kinds of comparative modeling and reasoning practices. Future studies should more deeply examine how to leverage lived and imagined experiences in comparative modeling and how a comparison might serve a counter-story (as in the flood case).

Abstract: Achieving data literacy is challenging when schools narrowly focus on statistical reasoning rather than on meaning- and inference-making. Without attention to the social contexts of data, learners can fail to develop a critical stance toward data, to understand the nature and production of data, the questions that it can answer, and the ways that data can be used to inform and misinform. We explore art as an accessible and personally relevant approach to developing middle school students' data literacy. We designed and implemented a 2-week long arts-integrated unit in a grade 7 classroom. Interviews with two teachers and two students following the unit, and analysis of students' artworks and pre/post survey responses, reveal opportunities and challenges at the intersection of data science and art. We discuss pedagogical considerations for other interdisciplinary approaches to data literacy.

Art as an approach to data science

It is essential that young people become data literate. With public and private institutions increasingly amassing personal data, learners must be able to think critically about the sources, representations, and claims being made about data. This reasoning includes an ability to understand the nature of data and how to extract meaning from data patterns, as well as to make critical inferences about data based on context, and the extent to which evidence from the data supports a claim (Makar & Rubin, 2018). Cultivating data literacy is challenging because school mathematics tends to narrowly focus on statistical reasoning, and to present data as objective and devoid of context (Franklin et al., 2015).

We explore an approach to broadening participation in data science by integrating art and mathematics in a middle school classroom-based unit. This project builds on existing efforts to tie school-based data literacy instruction more closely to personal and social contexts (e.g. Kahn, 2020) by incorporating an interdisciplinary focus on art (c.f. Lupi & Posavec, 2016). Interdisciplinary approaches to mathematics and data literacy can be valuable for engaging students who are disengaged in mathematics and can support deeper data literacy learning (Stornaiuolo, 2020). It allows learning through the making process through which learners can engage in meaningful reflection (Turkle & Papert, 1990). Moreover, *data art* is a distinct art form that engages audiences with both emotional and intellectual properties of data (D'Ignazio & Klein, 2020; Hall, 2008). In negotiating these priorities, the artist represents the situated nature of data, a fundamental principle of critical perspectives.

We explore a form of data-driven art-making, in which learners identify a message to convey, reflect on the different perspectives and complexities involved in a data set, and determine how to use materials to communicate that message to evoke a desired reaction from an audience. As students engage in asking questions, gathering and interpreting data, and communicating an evidence-based claim or argument to inform or persuade, our conjecture is that an arts-based approach will encourage a critical perspective on data that is often absent from mathematics alone. Such a perspective would involve connecting data to context, identifying patterns in data at an aggregate, and weighing the warrant of the data for supporting arguments or claims (Makar & Rubin, 2018).

To examine the opportunities and challenges in students engaging in art-making for data literacy, we designed and implemented a unit, and asked: (1) *What value do teachers perceive in an arts-integrated approach to data science?* and (2) *How does this approach engage students with data?* By understanding teachers' goals and students' experiences, we can better design similar interdisciplinary activities that are feasible for the classroom.

Methods: Context, participants, and data

To explore the value of an arts-integrated approach to supporting data literacy, we co-designed and implemented a unit with two teachers, one art teacher (Kelly, female) and one math teacher (Bruce, male)) and their 25 seventh grade students. Kelly and Bruce teach at the same private school in the United States, in which their administration encourages interdisciplinary connections between subjects. Kelly and Bruce identified the theme of social interaction, which they felt would interest their students. The two-week unit was presented as a way for the students to explore the theme using both data and art through two activities: (1) a data drawing, which involved students collecting, organizing, and visualizing data using hand-made drawings to reveal patterns about their everyday social experiences (e.g., the number of times they heard the word "pandemic;" number of conversations they had and with whom); and (2) a data sculpture, which involved students using materials found in their homes to communicate a pattern found in their exploration of data on teens' use of social media. For this activity, we provided students with a tool (bit.ly/sm-pew) to explore an existing data set on teens' use of social media (Pew Research Center, 2015). This tool allowed students to explore the responses to survey questions (e.g., "Does social media make you feel better connected to your friends' feelings?") and group the data based on characteristics (e.g., gender, age, race/ethnicity, etc.). Because of the COVID-19 related school shutdown, students completed the activities asynchronously from their homes, sharing photographs of their artwork with peers, and responding to reflective prompts using the Web-based Inquiry Science Environment (WISE, wise.berkeley.edu). To support students' navigation through the unit, teachers corresponded with students via email and Google Classroom, and facilitated optional virtual synchronous check-in sessions once per week.

Our data consist of (1) a post-unit group interview with two students (whom we name Ariel (female) and Yamil (male)), which asked them to reflect on their experiences during the unit and to elaborate on the decisions they made in creating their artwork; (2) individual post-implementation interviews with each teacher, in which we ask them to reflect on how the unit met or failed to meet their learning goals, and on notable observations of student learning; (3) student artifacts (artwork, artist statements, and written reflections on their processes); (4) responses to a pre and post survey that probed students' engagement and self-perceived competencies in math and art, and their abilities to critique existing data-based art; and (5) researchers' reflections on our experiences co-designing the unit over the several months prior to its implementation, and in supporting teachers throughout its implementation. Three researchers conducted a thematic analysis of the data using an open coding approach to develop descriptive categories, and refining these through discussion and re-reading of transcripts (Saldaña, 2015). To answer RQ1, we describe the key themes that emerged from our analysis focusing mostly on the interviews with the teachers. To answer RQ2, we use our multiple data sources to construct narratives of students' experiences. For the purposes of this paper, we focus on students' data sculptures.

Findings

RQ1 What value do teachers find in an arts-integrated approach to data science?

The teachers indicated three main benefits from implementing an arts-integrated approach to data science with their students. First, it enabled students to contextualize ideas in the real world, increasing their awareness of the applications of art and math. Kelly noted that she "liked showing students why people create art (…) that it's more than just being an artist." She stated that a valuable part of the activity was showing students that "art can also help us understand concepts in other fields," and that data-based artists "exist and (...) this is an option for them instead of doing the graphs and the bar charts, you could make it more expressive (...) you can kind of go further with your statistics." Similarly, Bruce wanted students to use mathematical tools to accomplish a meaningful and practical goal, "not only are they working with the numbers, but they're taking that information and then doing something else with it, with the hope that it'll you know stick in their brain a little bit." Additionally, an arts-based approach was seen as important for students to recognize the real-world implications of data. Kelly observed that the activities allowed students to see "the overall story of the numbers, they were looking at. It wasn't just 90% of this or 40% of this. They saw: 'OK, so real people. So I'm going to tell the story of the person.' So that (...) puts a narrative into their math class."

Second, the teachers chose this curriculum to provide students with opportunities to use art and math to pursue their own interests. For example, Bruce appreciated that students "had to come up with their own question, and (...) find a topic they like to learn." He also noted that although the activity was less math-focused than he would typically assign, it was especially appropriate for asynchronous learning. Students "were able to do something that they might enjoy for school work" while incorporating diverse materials, connecting to "a lot of different topics and com[ing] up with their own ideas." Kelly also noted the ways that students seemed to build personal relevance, "I think [the topic choices] were very relevant to them because you know you can see in some of their storytelling, you know it sounds like they were kind of talking about their own experience".

Third, the curriculum provided new ways for students to work with data, demonstrate their understanding, and facilitate assessment of students' learning. Bruce noted that these types of interdisciplinary approaches provide him with an opportunity to promote inclusivity by helping him "make things, both the information and the assessment of what they've learned, kind of accessible to as many students as I can." By providing many options he hopes learners can “find their comfort zone.” The unit also provided new ways to assess learning, particularly how and whether students were able to transfer knowledge across contexts. He could see that the students were “not just regurgitating information exactly the way it was taught to them. They were shown some examples of how to read this data, what they could do with it, and they proved that they were able to do independent thinking with that by doing different types of projects that we didn't show them. (...) they have to be able to make inferences about the data (...) and the project was a good way to assess that.”

RQ2 How did students engage with data through art?

Ariel. Ariel’s pre and post-survey responses showed she developed a new awareness of the relationship between data and art. By the end of the unit, she expressed a belief that the quality of data-driven art resides in “how much [it] can show the meaning of a graph...” Ariel began the data sculpture project by exploring the Pew data set. She was intrigued by how frequently teens’ used the internet, a finding based on a graph titled “overall, how often do you use the internet?” From this discovery, she attempts to answer “how the internet can be impactful on the minds of teenagers.” She then misrepresented the data by making a claim grounded in her own perceptions of teens’ internet use: “social media appear to affect different people in different ways by finding what they are interested in, attracting them into that subject, and making you lost into the world of social media.” Using this statement, she mapped variables onto different visual attributes (Figure 1, left) to contrast teens who do and do not use the internet.

Ariel used the colors and arrangement of crayons, scissors, and hair elastics to symbolize the attitude differences she perceived between the two groups. The open scissors and scattered arrangement of objects in one pile represents the “open-mindedness,” imagination, and inclination toward “drama” that she perceived in teens who use the internet. Meanwhile the circular shape of the hair elastics and the square arrangement of crayons in the second pile represent people “circling around a topic,” who avoid the internet, and whom she presumes are more “organized, more ordinary (…) [and who] focus on educational stuff.” Kelly admired Ariel’s use of symbolism, and was surprised at how it differed from Ariel’s typically conventional artwork.

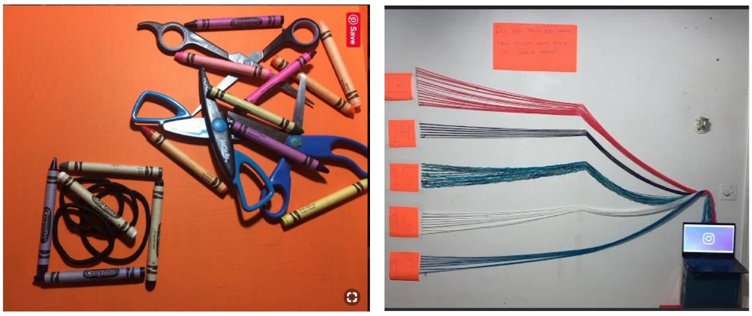

Figure 1. Data sculptures from Ariel (left) on the impacts of the internet, and Yamil (right) showing teens who “disagree” with the statement “Do you think age impacts how much teens share on social media?” by age.

Yamil. Based on his pre-test, Yamil had difficulty evaluating the quality of data, and making accurate claims based on graphical representations of data. He began his data sculpture by seeking relationships in the Pew data that he believed would be interesting to a wide audience (pre-teens and parents). He chose to communicate the relationship between young people’s age and their attitudes toward sharing personal information on social media. He first tried using clay to represent this relationship, but when he could not accurately scale his sculptures to the data, he abandoned this medium in favor of yarn. He pinned the yarn to a wall, distinguishing age groups by the yarn’s color, and mapping the number of strands to the number who disagreed with the claim.

Kelly, who shared that Yamil was one of the more creative students, noted surprise at the resemblance of his artwork to a canonical graph. At the same time, Yamil had misinterpreted the data set in multiple ways. His title, “Younger age group reveal more personal information on social media,” suggests that Yamil believed the data to be about how much information teens share, rather than teens’ perceptions of how much others share on social media. Moreover, the decisions he made for practical reasons seemed to have led to misrepresenting the data. More specifically, instead of showing each of the 1,060 survey respondents, Yamil transformed and filtered the available data, reinterpreting the Likert scale as a binary yes/no question, and representing only the respondents who disagreed with the focal statement. By representing only a fraction of the sample and using sums rather than percentages, he overlooked the fact that 80% of 13-year olds actually believe that people share too much personal information. It seemed that Yamil’s expectation that “older kids know more” (as in, they know better than to share personal information online) prevented him from recognizing his misinterpretation.

Discussion and significance

In exploring how teachers and students experienced an arts-based approach to data literacy, we found that students generated unique questions, negotiated relationships between data and materials, and made claims that attempted to go beyond the data. Ariel conveyed meaning through the color, shape, and organization of materials, while Yamil used an unconventional material (yarn) to construct a conventional representational form. Both students ultimately drew on personal beliefs rather than on the data as evidence to support their claims, a difficulty identified by Hug & McNeill (2008). By examining their process, artifacts, and reflections, we identify opportunities to better support students' informal inferences through art-making.

First, while Kelly and Bruce both highlighted the chance for students to pursue their interests through this unit as an opportunity, students struggled to communicate personal perspectives that were also grounded in data. Ariel and Yamil incorrectly interpreted data when pursuing questions that were personally interesting to them, rather than develop new questions, answerable with the data available. This shows the difficulties of working with data as an artistic material, that is, in negotiating its affordances and constraints for communicating a perspective to an audience. The mandated asynchronous format limited the discussion that teachers would have facilitated to address such issues. To scaffold students' sense-making, future iterations might incorporate tools and routines of authentic artistic practice, such as with tools such as peer and public (Soep, 2005), wherein students can iterate on their ideas, examine their biases, and test their artistic choices.

A second challenge was in defining data art. Yamil made a functional data art sculpture, offering his audience a tool for discovery by attempting to represent the data objectively. Ariel, on the other hand, made an expressive data art sculpture, connecting her audience to the topic through a feeling or concept. Both students showed difficulties in making and communicating informal inferences about data, either being unable to go beyond the data or using data as little more than inspiration. It is essential to support reflection on how choices about data skew toward either extreme, and to support students in iterating toward the center. In future, we will find ways for students to create personal connections with broader social patterns found in data.

This study highlighted the opportunities in an arts-based approach for allowing students to make inferences that give data personal and social meaning. It also emphasized the need to ensure that students are grounding their interpretations in evidence. Findings will inform future research and design on arts-based data literacy and art at the middle school level.

Abstract: Research has shown that tape diagrams are beneficial for algebra learning. However, it is unclear whether certain visual features of tape diagrams have implications for learning. We investigated, with undergraduate students and math teachers, whether tape diagrams with different visual features (color, presence of outer lines, and position of the constant) differentially support reasoning about equations and whether people have preferences for certain visual features. Variations in visual features did not affect students' or teachers' reasoning accuracy; but each group displayed systematic preferences for most visual features considered. Future research should examine the effects of these visual features on performance while solving equations.

Introduction

Diagrams are a valuable tool for helping students understand mathematical concepts and procedures (e.g., Chu et al., 2017; Murata, 2008). Diagrams are thought to support students in solving problems, understanding structural relationships, and building conceptual understanding (e.g., Larkin & Simon, 1987). As such, curricular standards, such as the Common Core State Standards for Mathematics (CCSSM, 2010), designate diagrams as important learning tools. The CCSSM specifically recommend a type of diagram called tape diagrams (henceforth TDs). In TDs, quantities are depicted in horizontal bars, similar to strips of tape.

One domain in which TDs may be especially useful is algebra. Algebra presents challenges to many students, in part due to an overemphasis in algebra instruction on procedural skills, rather than conceptual understanding (Richland et al., 2012). Past work has suggested that TDs may support students in generating and solving algebraic equations (Booth & Koedinger, 2012) and in transitioning from informal to formal strategies (Nagashima, Bartel et al., 2020). TDs thus appear to hold promise for supporting algebraic thinking.

A close inspection of the literature on TDs indicates that visual features of TDs vary substantially across studies, raising the questions of whether particular visual features influence performance, and whether teachers or learners have preferences for specific visual features. Both questions are important when designing instructional materials, because small variations in design features can lead to large variations in learning (e.g., Barbieri et al., 2019).

One relevant study sought to analyze the affordances of TDs for student learning using a qualitative, teacher-centered approach termed Pedagogical Affordance Analysis (PAA) (Nagashima, Yang, et al., 2020). This study identified an optimal design for TDs based on substantial input from teachers. In a later classroom experiment, such TDs enhanced students' conceptual knowledge when used in early algebra learning activities (Nagashima, Bartel, et al., 2020). However, it remains unknown whether specific visual features have differential effects on student performance, or whether students' preferences align with the preferences of teachers. Understanding students' and teachers' preferences may inform researchers and practitioners who design instructional materials. Further, it is possible that a misalignment between the preferences of students and teachers could lead to misconceptions or student disengagement.

In the present investigation, we address three corresponding research questions: (1) What visual features of TDs help undergraduate students and math teachers accurately symbolize equations? (2) What visual features of TDs do students and math teachers prefer? (3) Do students and math teachers believe that TDs are useful, and do these judgments relate to their performance when working with TDs?

Method

Participants

We collected data with two samples of participants: undergraduate students ($N = 50$) and math teachers in the US ($N = 163$). Undergraduates were recruited through an introductory psychology participant pool at a Midwestern university; teachers were recruited via postings on social media. Per self-report, the student sample was 56% female and 36% male; 8% declined to report gender. The student sample was 78% White and 20% Asian; 2% declined to report race or ethnicity. Students had varying levels of math knowledge, with 18% of students having never taken Calculus, 68% of students having taken one or two semesters of Calculus, and 10% having taken beyond two semesters of Calculus; 2% declined to report. The teacher sample was 49% female and 49% male; 2% declined to report gender. The teacher sample was 50% White, 15% Hispanic/Latinx, 14% Black/African American, 8% Asian, 5% Native American, 2% Native Hawaiian/Pacific Islander, and 4% multiple races/ethnicities; 2% declined to report race or ethnicity. On average, teachers had 9.4 years of experience (*SD* = 7.1). 121 (74%) of the teachers reported having seen TDs in the past, and 113 (69%) reported using diagrams similar to TDs in their teaching. Of the teachers, 48% taught grades 1-5, 31% taught grades 6-8, 11% taught grades 9-12, and 8% taught multiple grades, with 2% teaching other grades or declining to report.

Design and procedure

Each participant completed an online survey via a web-based platform. In the survey, participants were presented with three tasks: Symbolization, Preference Ratings, and Ratings of Perceived Usefulness.

Symbolization Task: Participants were presented with TDs and were asked to generate corresponding equations. For example, participants might be presented with the TD in the first row of Table 1 and be asked to generate the corresponding equation (the correct answer is 4x + 4 = 30). The diagrams varied in visual features, including whether or not they used color, whether they included vertical lines, and whether the constant was on the top or bottom tape. Responses were coded as correct or incorrect. Undergraduates were asked to symbolize six one-operation and six two-operation equations; teachers were asked to symbolize four equations of each type.

Preference Ratings: Participants were then shown 12 pairs of TDs that varied by one feature and were asked to choose which TD best represented the equation (see Table 1). Following this task, participants responded to a set of general questions regarding their preferences (e.g., "What features did you like/dislike about the tape diagrams you just saw?"). Responses were coded for the specific visual features and for whether they noted *aesthetic* or *conceptual* reasons for liking or disliking a feature (see Table 2).

Table 1: Variations in visual features of diagrams.

Equation	Feature	Examples
4x + 4 = 30	Color	8 + 9x = 26	Constant Location	4x + 6 = 50	Line	
2x + 9 – 9 = 27 - 9	Dynamic: Subtraction	5x + 7 – 7 = 37 -7	Phantom Dashed: Subtraction	3x = 12	Full Dashed vs. Phantom Dashed: Division	
Ratings of Perceived Usefulness: Participants responded to questions about the perceived usefulness of TDs on a five-point Likert scale (Strongly Disagree to Strongly Agree) (e.g., "Tape diagrams helped me represent the equations"). They also responded to three questions regarding whether they thought younger students would find TDs helpful or not helpful (e.g., "Tape diagrams would help younger students represent equations").

Results

We first analyzed whether specific visual features influenced participants' abilities to generate equations to correspond with TDs. Success on the one-operator items was at ceiling, so we focus here on the two-operator items. Based on previous research (Nagashima, Yang et al., 2020), we selected the "baseline" TD as including color, including outer lines, and having the constant on the bottom. We then compared each of the variants to this baseline. Thus, the TDs were categorized into four groups: baseline, baseline without color, baseline without outer lines, and baseline with the constant in the top tape.

Undergraduates performed similarly at symbolizing all four types of TDs ($M = .69$, $SD = .06$), $F(3, 196) = .54$, $p = .65$. Likewise, teachers also performed similarly at symbolizing all four types of TDs, ($M = .44$, $SD = .04$), $F(3, 486) = .83$, $p = .47$. Thus, variations in visual features did not affect symbolization accuracy.

We next analyzed whether participants preferred specific visual features. We evaluated the same features used in the symbolization task, as well as additional features that represented intermediate steps in equation solving (Table 1). Descriptively, both students and teachers had general, group-level preferences for four of the six features: use of color, having the constant in the bottom tape, using full dashed lines to represent division, and using phantom dashed lines to represent the removal of break-away pieces (Figure 1). The only feature for which there was no clear preference in either group was representing subtraction with dynamic break-away pieces vs. a static representation.

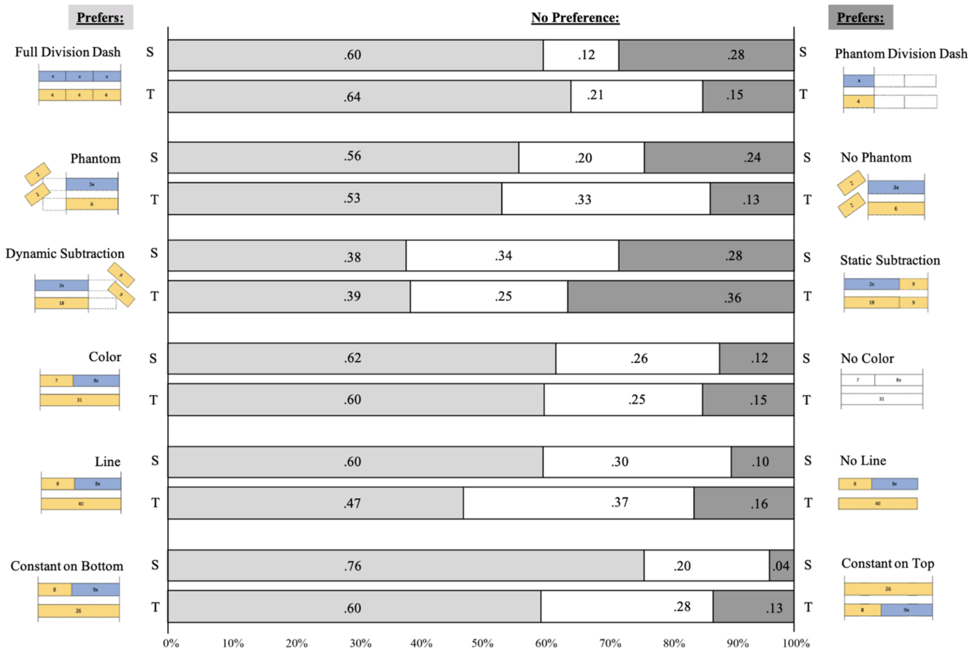

Figure 1. Preferences for TD visual features as a function of specific features and whether the participant was a student or teacher. "No preference" ratings indicate participants who were inconsistent in their ratings (e.g., stating that they preferred color on the first trial and no color on the second trial).

Table 2 presents data on participants' responses to the open-ended questions (e.g., "What features did you like about the tape diagrams you just saw? Be as specific as possible"). Descriptively, across groups, the majority of responses focused on either color/no color or line/no line. Students tended to provide aesthetic reasons for their preferences, while teachers tended to provide conceptual reasons. Teachers mentioned the representation of intermediate steps (e.g., dynamic subtraction) more frequently than students.

Table 2: Number of students (S) and teachers (T) who provided aesthetic and conceptual reasons for their preferences for specific types of TDs.

	Aesthetic			Conceptual		
	Like	Dislike	Example	Like	Dislike	Example
Color v. No Color	S: 20 T: 5	S: 6 T: 7	"I liked the different colors used…"	S: 8 T: 17	S: N/A T: 11	"I liked the colors to distinguish constants from expressions with *x*"
Line v. No Line	S: 8 T: 1	S: N/A T: 1	"I like the bars on the ends"	S: 4 T: 12	S: 1 T: 1	"I also liked the vertical lines to show clearly that the two values were equal"

Finally, we asked whether participants viewed TDs as useful for supporting equation solving. For each sample, we regressed the percent of equations that participants accurately symbolized on their self-reported usefulness of TDs score. For both samples, the more useful participants perceived the TDs to be, the higher their accuracy at symbolizing (students: $F(1,48) = 6.03$, $p = .017$, $R2 = .11$; teachers: $F(1,161) = 87.17$, $p < .001$, $R2 = 35$). Undergraduates rated TDs as more useful for younger students than for themselves, $t(49) = 4.42$, $p < .001$, whereas teachers rated TDs as equally useful for younger students and themselves , $t(163) = .24$, $p = .81$.

General discussion

Both students and teachers preferred TDs that used color, represented the constant in the bottom tape, used full dashed lines to represent division, and used phantom dashed lines to represent removing break-away pieces in subtraction. A smaller majority preferred outer lines. Participants based these preferences on aesthetic and conceptual grounds, with teachers' preferences being primarily conceptually based. Variations in visual features did not affect undergraduates' or teachers' success at generating equations to correspond to the TDs.

For teachers who wish to use TDs in instruction, this information about preferred features may be useful. Building on their pedagogical content knowledge, teachers may integrate the preferred TDs in lessons, for example, to illustrate solution procedures or to support self-explanation activities. Using TDs with preferred visual features may promote students' enjoyment of and engagement with the material.

In both samples, success at symbolizing TDs was associated with the perceived usefulness of the diagrams. Some participants may have understood the conventions upon which TDs are based better than others, and this third variable may have given rise to the observed association. Participants who viewed TDs as useful also tended to judge that they would be useful for younger learners. Future studies should investigate younger students' preferences for visual features and should examine whether visual features differentially support learning and symbolization in younger students.

In sum, this study revealed systematic preferences for visual features of tape diagrams in both teachers and undergraduates. These preferences can inform the design of curricular materials that involve such diagrams.

Student Epistemic Agency and Coherence-seeking through Laboratory Experiments

Lisa Hardy, Concord Consortium, lhardy@concord.org
Colin Dixon, BSCS Science Learning, cdixon@bscs.org

Abstract Overly simplistic school science laboratories constrain student agency. We share and discuss a case from 9th grade science classroom in which students all conducted highly varied independent investigations that were each highly coherent and scientifically well-motivated. We discuss the conditions that led to their experiments in terms of instability and uncertainty. Our findings suggest that it may be beneficial to support and recognize multiple forms of uncertainty simultaneously to encourage multiple forms of investigation to respond to those uncertainties. Finally, an "instability" caused by having *multiple* candidate models or explanations in play may be more generative than uncertainties based on gaps in knowledge.

Introduction

Recent efforts in K-12 science education have focused on the design of coherent curricular "storylines" (Sikorski & Hammer, 2017). Rather than "pre-meditated coherence" as a property of the curriculum, Sikorski and Hammer (2017) suggest that coherence should be seen as an emergent result of students' coherence-seeking. For this to be fruitful, students must be positioned with the epistemic agency to seek coherence for themselves— yet this still is rare within school science activities (Greeno, 2006; Miller, Manz, Russ, Stroupe & Berland, 2018). As a field, we are beginning to recognize that students must be positioned with epistemic agency throughout the full cycle of scientific inquiry—deciding on phenomena of importance, approaches to studying it, what forms of data are useful to collect, how to represent and analyze that data, and in argumentation from evidence.

However, when it comes to laboratory work in school science curricula, students are rarely positioned with epistemic agency. Epistemic agency involves students being "positioned with, perceiving, and acting on, opportunities to shape the knowledge building work in their classroom community" (Miller, Manz, Russ, Stroupe & Berland, 2017). In particular, experimental design, research questions, and methods of collecting and analyzing data are often strongly prescribed (Greeno, 2006; Hardy, Dixon & Hsi, 2020). Supporting student agency in inquiry requires educators to move beyond "cookbook" scientific investigations, to investigations that are motivated by student questions and ideas, and designed, carried out and iterated on by students. Doing "real science"— with the full complexity, uncertainty and messiness that it entails— is often in tension with narrow conceptual learning goals (Hardy, Dixon & Hsi, 2020). Moreover, school laboratory investigations rarely allow for or resemble the various forms of "coherence-seeking" found in professional scientific practice (Chinn & Malhoutra, 2002). Frequently, students all do the same experiment in parallel, or work to investigate the same underlying "driving question." Commonly, as part of teaching a "control of variables strategy," students may be asked to identify a parameter to vary regardless of whether "fair testing" or controlled experiments are actually motivated or appropriate.

Productive uncertainty

Building uncertainties into epistemic work may be a fruitful way to support both student epistemic agency and authentic scientific activity (Manz, 2018). Contending with uncertainty is an important component of science learning (Metz, 2004). Uncertainty has primarily been discussed as a sort of cognitive or metacognitive state of not knowing, for example in qualifying claims in the context of argumentation (Metz, 2004). In other views, uncertainty characterizes a state of ongoing activity that is recognized, maintained, or resolved by participants by re-organizing social or conceptual resources for that activity (Kirch, 2010). Uncertainty can thus play an important role in science learning by opening space for students to exercise agency. Uncertainties can be strategically designed into classroom activity such that students have opportunities to negotiate the forms of data to collect, how to represent data or phenomena, and what counts as evidence (Metz, 2004; Lehrer, 2009; Manz, 2015). Manz (2018) argues that this *productive uncertainty* should be evidenced by a variability, rather than convergence, of student ideas and questions and approaches. However, traditional laboratory investigations in science classrooms rarely promote a productive uncertainty, with the aims and results of these experiments often known in advance, and with a straightforward conceptual interpretation arrived at similarly by all students. The field needs a better understanding of how disciplinary uncertainties and ambiguities can be designed into students' laboratory work in ways that support student agency and deepened engagement in practice.

Instabilities in science practice

The view of *uncertainty* as a state of ongoing activity resonates with descriptions of science practice as an iterative, goal-directed "mangling" (Pickering, 2010) of conceptual, material and social resources. In Pickering's view, the material world resists the scientists' efforts to know and control; the scientist exercises agency in determining the future course of the activity by shifting goals, revising conceptual understandings, or modifying instruments and material practices. Over time, knowledge is established through processes of *stabilization* of these various elements of scientific activity. In authentic scientific investigations, there are many possible pathways forward; moments of 'material resistance' (Pickering, 2010) are characterized by uncertainty not only in how to interpret data but how to proceed in inquiry. Thus moments of material resistance are periods of *instability* in scientific activity, in which scientists exercise conceptual agency (Pickering, 2010). We conceptualize students' epistemic agency as an extension of Pickering's notion, to include the ways that students reorganize activity to align with their own interests, objectives, or desired learning trajectories. This includes shifting or forming new goals, or re-organizing conceptual (e.g., re-thinking, re-explaining, revising models) or social resources (e.g., taking on a new role, positioning someone else in a new role, drawing on available expertise in new ways). Our hypothesis is that uncertainty, as a form of instability in scientific activity, can provide opportunities for students to exercise conceptual agency, and align their empirical investigations with their own areas of interest or goals.

Research context and data collection

Our data come from a research project to design sensor-based labs that support computational thinking through data acquisition and control. Our designed activities were used in three 9th grade Integrated Science classes at a large urban public charter school in Northern California, taught by Mr. B. Over two weeks, students were introduced to the sensors and software, and conducted two investigations related to photosynthesis and cellular respiration. In the first investigation, students observed changes to carbon dioxide levels in container of spinach leaves when it was placed either in the dark or in the light. After a discussion of the results of that investigation, the students then conducted follow-up experiments of their own design. We observed all class sessions, video-recorded selected groups of fully consented students, collected written student work, and conducted follow-up interviews with 18 student participants about their experiences and their final investigations. One aim of our analysis, at this stage, was to better understand opportunities for student epistemic agency within the curriculum, and in particular how material resistances, or surprising "pushback" from the material world, may provide opportunities for student agency.

Case report: Student responses to instability and uncertainty due to an anomalous dataset

Part 1: Instability and uncertainty

After the initial introduction to the sensors and software, students were tasked with collecting data about the relationship between light intensity and CO2 levels in closed containers of spinach leaves. The teacher showed the students a demonstration setup that consisted of a plastic container, sealed with plastic wrap and placed inside a cardboard box that both held the lamp above the spinach leaves, and blocked out stray light. Over two class periods, each small group built a similar setup, and collected CO2 data under two conditions: with the spinach leaves under a bright lamp, or in the dark. With the light off, cellular respiration in the leaves will increase the CO2 levels in the container. When the light is turned on, the leaves then photosynthesize, and the carbon dioxide levels drop.

In each period, after groups had collected their data, Mr. B facilitated a discussion of the results. He began by establishing a class consensus about what trends they had seen in their data (carbon dioxide levels rising in the dark, and dropping in the light). Students readily offered the explanation that the levels dropped in the light condition due to photosynthesis. However, as we expected, they were surprised and perplexed by the rise in CO2 levels in the dark. Mr. B elicited the students' ideas about why they might rise in the dark. In each class section, some students attributed the rise to a reversal of the photosynthetic process of taking in CO2, and others to the idea that spinach was dying, and/or decomposing, when the light wasn't on to sustain the plant's health. In each class, Mr. B noted the surprising results, and their collective uncertainty about the explanation.

However, in Mr. B's Period 2 classroom, this discussion proceeded differently. Fernando's group had contributed a dataset that was very different than the others. Instead of constructing the cardboard box to hold the lamp vertically, they placed their lamp on the table nearby the container of spinach, such that when the light was on it was effectively at a much lower intensity. As a result, instead of the carbon dioxide levels going up in the dark and down in the light, Fernando's went up in the dark, and up (just more slowly) in the light. When he showed his data to Mr. B, Fernando initially thought he would have to re-start a botched experiment. However, Mr. B recognized the value of this anomalous dataset and brought it to the other students' attention.

In the next session, the class discussed their experimental results. Akeem suggested that the rise in CO2 was due to the plants decomposing when in the dark. Raeleen expressed skepticism about this explanation. Alejandra brought up Fernando's data, which showed the leaves releasing CO2 even when the light was on. This suggested to the class that rising CO2 levels may not be due to decomposition of the leaves. Fernando then took up the position within the discussion that plants are *always* releasing carbon dioxide, but photosynthesis may happen in parallel, just more or less slowly. Akeem wondered aloud how this would happen— whether the plants are doing something like breathing in and out. As in his other two class sections, Mr. B left the discussion in a state of uncertainty, and directed the students to design and carry out follow-up investigations.

Part 2: Student follow-up investigations

In Mr. B's two other sections, students chose many different variables to investigate: the intensity of the lamp, the color of the light, the type of plant, whether spinach leaves were kept in a sealed or open container, the age of the spinach leaves, or even to use leaves before and after being cut from a whole plant. Of these experiments, only this last one was conceptually motivated by their previous experimental results or the discussion of them. This group hypothesized that the rise in CO2 would no longer happen if they could keep the leaves from dying, by leaving them attached to the plant. In contrast, the students in Period 2 who had discussed Fernando's data each took on a variety of projects directly motivated by the previous experimental results and discussion. Below we briefly describe each group's follow-up experiment.

Fernando: Seeking additional data

Fernando requested an oxygen sensor to add his experiment. Oxygen sensors were not already available in the hardware kits, so we brought him a prototype. He wanted to re-do his first experiments, while additionally monitoring the oxygen levels as the carbon dioxide levels changed to see how they could be related.

Alejandra and Linda: Investigating an alternative hypothesis

Alejandra and Linda did not agree that Fernando's dataset was different because his light was effectively dimmer. Instead, they thought that his lamp did not heat the spinach as much as other students', and that the release of carbon dioxide could depend on temperature. They used their project as an opportunity to investigate this alternative hypothesis, through a unique experimental design to create extreme temperature conditions. They heated spinach in a water bath, and froze spinach in a freezer.

Akeem and Maala: Model development

Akeem initially thought that the plants were decomposing at night and releasing CO2, though this was challenged by Fernando's data, which showed carbon dioxide being released even in the light. Akeem was curious how the plants could both take in and release CO2, and thought that the plants might be doing something like breathing. He then reasoned that changing the amount of CO2 in the container might affect how quickly or slowly the plants breathe in or out CO2. Akeem and his partner Maala followed up by investigating the effect of starting CO2 levels on the plants' absorption or release of CO2, breathing into the containers to create the different starting concentrations.

Raeleen: Realizing implications

As Fernando's data showed that CO2 levels could either go up or down depending on light intensity, Raeleen recognized that this implied that they could find a balance point at which they remained steady. Her project became to create "flat data" by incrementally adjusting the light intensity. Her group added sheets of wax paper in between their lamp and spinach leaves to gradually dim the light.

Discussion

Each of the groups in Period 2 pursued investigations that were coherently linked to and motivated by Fernando's dataset and their own thinking about its explanation or implications. This contrasts with Mr. B's other two periods, in which students primarily conducted investigations that did not substantially build on the previous results or discussion. In Periods 1 and 3, there *was* a recognized gap in knowledge— no one was quite certain how to explain the rise in CO2 levels. This illustrates that simply *not knowing*— or, recognizing gaps in knowledge (here, their ability to explain the rise in CO2 levels)— is an insufficient condition for maintaining and motivating coherent inquiry "storylines." In particular, prescribing "fair testing" experiments, despite the apparent choices and design decisions involved, may fail to position students with epistemic agency by severing (potentially) continuous epistemic threads.

In contrast, in Period 2 there were many acknowledged sources of uncertainty, beyond the lack of explanation for the rise of CO2 levels: uncertainty about particular claims (whether the plants were indeed dying at night), mechanisms (whether plants do something like breathing), evidence (what did Fernando's data really mean?) as well as implications of their results (could the data ever be flat?). Further, the instability inherent in having *multiple* candidate models or explanations in play may have been more generative than uncertainty based in gaps in knowledge. This broader set of recognized uncertainties allowed for a variety of student independent projects to all remain conceptually tied to the classroom inquiry. Thus, we see uncertainties as opportunities for students to exercise epistemic agency, and to contribute uniquely to the scientific activity.

We agree with Sikorski and Hammer (2017) that coherence is an emergent property of student sense-making. To fully support student epistemic agency, even in laboratory investigations, we will need to allow for more variation in student empirical work. Our findings suggest that it may be beneficial to support and recognize multiple forms of uncertainty simultaneously, and to encourage multiple forms of investigation to respond to those uncertainties. Further, we will need to design ways to make students' varied individual contributions to epistemic work explicit— to ultimately weave together students' continuous epistemic threads, at the classroom level, into a collective tapestry.

Conclusions

To design for student epistemic agency in laboratory work we must consider and support forms of investigation beyond students all replicating the same experiment, or each investigating the effect of single variables. Instead, we can allow students to respond to various forms of uncertainties or instabilities with more varied forms and goals of empirical work (e.g. seeking additional evidence, investigating an alternative hypothesis, investigating a particular model, or realizing implications). This will involve creating and recognizing multiple forms of uncertainty and instabilities, and positioning students as capable of managing or responding to them.

Abstract: Western science privileges particular ways of knowing nature and ignores nature as a cultural construct, which results in normative ways to describe the human-nature relationship in learning. Our work as a team of Indigenous and non-Indigenous K-12 educators, learning designers, and university researchers seek to join existing efforts to create transformative science learning. We explore how we can use place-based learning to engage learners with diverse ways of knowing and being, particularly through transcending typical Western ideas of a separated human and nature relationship. In this short paper, we focus on how Naomi, a sixth-grade student, represented her class field trip experience and negotiated the human-nature relationship through restorying. Naomi's restorying demonstrates the main characteristics of socioscientific perspective taking across different layers of her story. Further research is needed to understand how restorying impacts learners' value orientations and supports socioscientific perspective taking.

Context

The rapid development of science and technology privileges science and its related disciplines in learning, which leads to the normative practices that value science over other disciplines and ways of knowing. Researchers have described the process as the scientific gaze, with which people tend to judge non-science with modern scientific standards (Mcneil, 2005). Although science is often seen as acultural, it is shaped by particular cultural, historical, and political beliefs and values and, thus, is one way of reality-making (Hu, 2019).

The dominance of Western science has resulted in the settled expectations in education. Harris (1995) used settled expectations to describe racial hierarchies that attach a set of assumptions, privileges, and benefits to being white. From this perspective, culture and nature are positioned in opposition, with culture being defined by whiteness (and more human) and nature being defined as property (and less than human) (Bang et al., 2012). The distinction between "fully" or "not fully human" explains the gradation of human beings (Smith, 1999), which demonstrates a particular human and nature relationship shaped by settled expectations. Bang et al. (2012) further argues that settled expectations, in schooling, leads to entrenched and hidden boundaries that "tend to control the borders of acceptable meanings and meaning-making practices" (p.303). In fact, Western education is often criticized for anthropocentric characteristics (Lindgren & Öhman, 2019), which represents a separation of humans from nature. The separated and anthropocentric understanding of the human and nature relationship is, however, one perspective of knowing, which often marginalizes other ways of knowing.

In response to these issues, we join scholars (e.g., Bang & Marin, 2015) who are pushing educational researchers to seek understanding "of divergences, convergences, and productive generativity between Western science and Indigenous ways of knowing to create transformative science learning" (p.530). In this paper, we explore how place-based pedagogy can engage learners with diverse ways of knowing and being in ways that transcend typical Western ideas of a separate human and nature relationship. Specifically, we investigate how sixth graders engage with human and nature relationships through a five-day field trip experience. Our study is centered on the following research question: *how do learners negotiate the human-nature relationship in their re-storying of a place-based field experience?* Our findings indicate that restorying of field trip experiences can prompt socioscientific perspective taking (Kahn & Zeidler, 2019). We discuss implications for schooling and future research.

Related literature

Restorying place

Knapp (2005) describes place-based learning as an "instructional approach designed to help students learn about the immediate surroundings by capitalizing on their lived experiences" (p. 278). Prior studies have found that place-based learning does not necessarily benefit learners by engaging them with diverse ways of knowing and being. For example, Friedel (2011) discussed that *Western-orientated* place-based learning could pose challenges and often causes harm to learners with Indigenous backgrounds. Thus, how humans relate to place is culturally varied, and the historical and persistent colonization and settling of the land has resulted in deep trauma for many minoritized communities. Kimmerer argues "our relationship with the land cannot heal until we hear its stories," which is a process she calls "re-story-ation" (Kimmerer, 2013, p.9). This process of "re-story-ation" demands a re-understanding and re-engagement with place from varying perspectives.

While re-story-ation manifests in many forms, in this paper, we connect it to the idea of restorying as a literary practice. Restorying is a learner's rewriting or retelling of "a personal, domain relevant story based on the application of concepts, principles, strategies and techniques covered during a unit or course of instruction" (Slabon, 2009, p.2). Therefore, learners can construct knowledge by reframing and making meaning of their previous experiences through narratives (Foote, 2015). As a pedagogical approach, restorying serves as an important means to engage learners with conceptual application, critical thinking, and ill-structured problem-solving skills (Slabon et al., 2014). In this paper, we seek to capture learners' lived experiences from their written restorying of their field trip experience.

Nature as cultural

Our work is rooted in the belief that nature is cultural; it is socially constructed and has cultural variations (e.g. Medin & Bang, 2014). Scholars have unpacked the cultural perspectives of nature through human and nature relationships. Gallagher (2001) argues that how people relate to nature is one of the key values that vary culturally. In the Value Orientation Model, he identifies three types of human-nature relationships: humans are subordinate to nature, humans are in harmony with nature, and humans are dominant over nature (Gallagher, 2001). The three different human-nature relationships are also associated with the psychological distance between human and nature. The psychological distance between humans and nature is one recognized aspect of cultural differences (Medin & Bang, 2014). Medin and Bang (2014) captured the differences into three categories. Specifically, "nature as the foreground" depicts human activities such as forest walks and berry picking and "nature as a background" depicts human activities such as playing sports. Other human activities that physically change nature can be seen as "intermediate," such as mowing the lawn. Furthermore, Medin and Bang (2014) found that both children and adults from urban and rural Native American communities are more likely to participate in practices with nature as the foreground. These models serve as practical tools for us to understand the relationships between human and nature that are represented in learners' experiences.

Methods

Context

The work presented in this paper is part of a larger, ongoing design-based implementation research (Fishman et al., 2013) project to understand how to design culturally centered sixth grade curriculum (Litts, Tehee, Jenkins & Baggaley, 2020; Litts, Tehee, Jenkins, Baggaley, et al., 2020). As a team of Indigenous and non-Indigenous K-12 educators, learning designers, and university researchers, we focus in this paper on how students restory their field trip experience. The research takes place at Edith Bowen Laboratory School (EBLS), a K-6 elementary public charter and Title I-Targeted Assistance school located in the Mountain West. We invited all 55 sixth graders across two classrooms in one school year, and 39 sixth graders fully consented. Participants were 11-12 years old at the time of data collection. The student demographics of the school are 86% White, 5% Multiracial, 6% Hispanic, 1% Black or African American, 2% Asian, 1% American Indian or Alaska Native, and 0% Native Hawaiian or Other Pacific Islander.

EBLS has a place-based learning emphasis and provides unique field experiences to students throughout their schooling. In this paper, we focus on a five-day field trip with three days and two nights river rafting on the San Juan river, a natural border with the Navajo Nation. During the trip, teachers designed structured engagements with nature and culture for students. For example, prior to visiting ancient ruins in the area, which are sacred lands to local tribes, Jen (Author 7), the Math and Science teacher, shared a short story written by a former student, who self-identifies with one of the local tribes, to highlight the significance of the ruins and promote respect of place (Litts, Tehee, Jenkins & Baggaley, 2020). Throughout the trip, Stu (Author 6), the English Language Arts and Social Studies teacher, employed the hero's journey narrative structure to frame the field trip experience. The hero's journey is a recurring template of many stories, myths, folktales, and legends that tells the story of a main character facing a significant life problem and setting off for an adventure to resolve it (Campbell, 1993). Upon returning from the trip, the students were tasked with restorying their experience through writing their own version of a hero's journey.

Data collection and analysis

As part of the broader project, we collected a range of data such as recordings of meetings, fieldnotes, and documentation of student work, as well as students' interviews and surveys conducted at three different time points throughout the school year. In this particular study, we focus on students' short story writings that they wrote based on their experiences during the trip. Even though the prompt for the story emphasized actual experiences, students could include fictional elements in their stories. To capture how students represented the relationship between humans and nature in their restorying, we constructed each story as a case and compared the specific ways in which students represented nature across cases (Stake, 1995). We triangulated themes with fieldnotes, teachers' perspectives, and students' interviews. In this paper, we present one case to illustrate how learners' negotiation of human and nature relationships in the restorying demonstrates perspective taking.

Findings

As a part of their collective experience, the sixth graders engaged with nature in multiple ways during the river trip. Naomi (pseudonym), an 11-year-old girl who identifies as white, was particularly drawn to the red rocks, which are unique compared to where she lives in the northern part of the state. She explained, "it was like, there was a lot of like rock there, like, pretty like rock…" (Naomi, Post Interview, 10/08/2019). Rock, in fact, is a significant feature of the natural landscape in the field trip area. This feature became the centerpiece of Naomi's hero's journey story, "The Rock". In this story, she introduces two main characters, which was a unique literary move compared to her counterparts: a talking rock named Ned and a 12-year-old boy named Aaron are the two main characters. Ned, the rock, lost his family in a flood and was eventually picked up by Aaron, the human, who was jogging by the river. Naomi writes,

> "The boy stared at the rock in confusion. Ned decided to start talking. This was his big moment. He had always wanted to talk to a human! The rock said, "I am Ned." The boy was startled! The rock said again, "I am Ned." The boy said, "I am Aaron." Without saying a word, he [Aaron] ran to the raft with Ned in his hand...Once they got to the mellow water Ned learned how to jump! He was jumping and bouncing around the raft having fun! Then Ned noticed Aaron's brand new phone on the ground! Ned couldn't stop bouncing and shattered his phone! He [Aaron] got so mad at Ned! Aaron [t]hrew Ned out of the boat! (Naomi, Short Story, "The Rock").

Naomi then follows Ned's perspective, "once [Ned] landed on the sand, Ned had to find his way to the end of the river. Now, Ned had to face his greatest fear, THE DARK! The first night he chose to keep walking 10 hours later, he faced his greatest fear." (Naomi, Short Story, "The Rock"). The next day, Aaron was preparing to leave the river, yet he felt remorse for what he had done to Ned. Naomi continues, "He turned around and saw Ned talking with his family!" The rock and the boy apologized to each other and Ned requested of Aaron, "throw me and my family up into the stars. If you do, we will turn into constellations. Then we can see the river forever!" (Naomi, Short Story, "The Rock").

Naomi's story shows two perspectives of one incident. It consists of two intertwined hero's journey stories: (1) For Ned, he goes through the separation from his family, fears and difficulties, and reunion with his family; (2) For Aaron, he changes from being angry that his phone was broken to feeling regretful about what he did to Ned and apologizes to Ned. The hero's journey is usually about the change of a single protagonist (Campbell, 1993), yet in this story, Naomi intertwines two perspectives to create a larger narrative. Even more than that, Naomi situates this all in a moral context with Aaron's struggle and empathy after expressing anger at Ned. The resolution of the story comes when Aaron moved beyond his own world to seek new understanding from Ned's perspective, and they reached harmony together as human and nature. Interestingly, this narrative arc demonstrates socioscientific perspective taking (Kahn & Zeidler, 2019), which is defined by three characteristics: "(1) engagement with others and their circumstances, (2) etic/emic shift, and (3) moral context" (p. 623). Naomi engages all three in her restorying of the field trip experiences.

Implications and future directions

One key insight demonstrated through this case that resonated across cases is that the sixth graders represented the relationships between human and nature through socioscientific perspective taking (Kahn & Zeidler, 2019). Naomi's restorying includes several layers of perspective taking that resulted in harmony between the rock and the human, which is a potential marker of Naomi's value orientation (Gallagher, 2001). Our data and analysis do not clearly indicate whether restorying is a *real* or *imagined* expression of students' value orientation toward nature or if restorying leads to a shift in value orientation, so further research is needed to understand the role of restorying in students' value orientations. We also note a need to further explore how we can support socioscientific perspective taking through restorying place-based experiences.

Abstract: Recent studies for developing CS identities promote interrogating dominant narratives about CS while learning computing in order to better understand how minoritized youth negotiate who they are and who they want to be in relation to computing and technology. In this study, we propose "restorying" as an approach to engage minoritized youth in examining dominant CS narratives while designing interactive, electronic textile quilt patches. Through analyzing interviews and participant artifacts, we present two case studies highlighting youth's reimagining of dominant narratives of CS as "boring" and for "only white men" as well as their future connections to computing. We discuss how engaging minoritized youth in restorying who they are becoming in relation to CS might help researchers and educators better understand ways to design learning environments that support their computing identity work.

Introduction

While major efforts are underway to bring computing into K-12 education, most have focused on examining how *all* students learn computational thinking concepts and practices. However, we cannot ignore how Black, Latinx, and Indigenous youth have been systematically denied access to quality computing learning opportunities (Margolis, Estrella, Goode, Holme, & Nao, 2008). Disciplinary learning is embedded with political and ethical values that promote particular ways of being that can support or limit minoritized youth's disciplinary learning and identities (Vakil, 2020), especially during an age when youth are asking critical questions about the roles computing and technology play in their lives and who they want to become. If we are to expand youth's connections to computing, we need to design learning environments that support the computing identity work of youth whose disciplinary learning experiences have been marginalized (e.g., raced, gendered, and classed) based on the dominant cultural values of that discipline (Bell, Van Horne, & Cheng, 2017). While CS identity has been a research focus since early computing education, it mainly focused on describing racial or gender demographics of research participants; what is less understood is how youth's multiple social identities shape learning processes and trajectories of future engagement with computing—both theoretically and empirically.

Recent studies have taken more action-oriented approaches towards developing positive identities in computing education. One approach uses STEM contexts to leverage minoritized youth's political and cultural identities by promoting critical reflection of equity in order to develop their critical computational literacies beyond technical skills (e.g., Lee & Soep, 2016). Another approach towards developing Black girls' interest and identification with STEM and computing involved researchers and youth co-designing counternarratives about girls in a parallel program who differ from dominant computing stereotypes as girls from different racial/ethnic backgrounds with diverse interests and computing experiences (Pinkard, Erete, Martin, & McKinney de Royston, 2017). However, youth provided feedback on narratives originally created by the researchers rather than constructing their *own* original narratives based on their own computing experiences.

We propose restorying as a novel effort for integrating computing identity work with the learning of computational concepts and practices through youth's creation of counternarratives about CS. An analytical concept prominent in literacy research, restorying is defined as individuals "[narrating] the word and the world, analyzing their lived experiences and then synthesizing and recontextualizing a multiplicity of stories in order to form new narratives" (Thomas & Stornaiuolo, 2017, p. 318). In addition to challenging the reproduction of dominant CS narratives, restorying also provides youth the space to *imagine alternate ways of being, thinking, and doing in computing* as they reimagine new connections to the discipline reflective of their multiple social identities and lived experiences. Here we want to examine how restorying as a learning practice can offer minoritized youth the opportunity to interrogate dominant CS narratives while learning computing so we can better understand how they negotiate who they are becoming in relation to computing and technology.

In this paper we present cases of Matthew and Layla, participants in a workshop we developed for a racially diverse STEM program at a local science museum, who designed interactive, electronic textile (hereafter, e-textiles) quilt patches that restoried dominant CS narratives. Through combining crafting, circuitry, and coding, e-textiles creators connect sewable Arduino-based microcontrollers with conductive thread to actuators (e.g., LEDs and sensors) to make interactive craft projects (Buechley, Eisenberg, Catchen, & Crockett, 2008), and broaden and deepen participation in computing. Building on frameworks of identity as narrative through the stories we tell about ourselves, others, and our experiences (e.g., Sfard & Prusak, 2005), minoritized youth in this study combined e-textiles with the historical practice of quilting to develop counternarratives about who participates in computing. To this end, we ask: What is revealed about computing identity work when high-school-aged youth design interactive, e-textile quilt patches that restory dominant narratives about CS?

Methods

Employing a social design experiment approach (Gutiérrez & Jurow, 2016), we facilitated a workshop during Spring/Summer 2020 for 19 participants (16 consented) from a racially diverse program at a local science museum serving high-school-aged youth who are passionate about STEM. Demographically, participants in the program consisted of 9 boys and 10 girls, and the racial/ethnic breakdown of youth includes the following: Black or African American (8 youth), Asian (5 youth), White or Caucasian (2 youth), Hispanic or Latinx (2 youth), and Other (2 youth) (anonymous demographic data was collected from the program manager and reflects descriptions used by the program).

The first part (4 hours) of the workshop was initially facilitated at the museum, but due to the COVID-19 pandemic, the remainder (30 hours) was facilitated virtually. Workshop activities included youth designing various artifacts representing their personal relationship with CS and computing, as well as class-wide discussions about the dominant (and concealed) narratives about CS and computing technology (including its history and representation), the history of quilting as a tool used by minoritized groups to resist dominant narratives, and the appropriation of computing technology to resist systemic oppression.

Data collected and analyzed included participants artifacts (e.g., photos and videos of youths' quilts in interaction, reflection worksheets, and design journals), researcher memos, and post-interviews of participants. We have begun initial rounds of comparative, inductive analysis of interview and worksheet data in order to develop a codebook and framework for understanding what restorying while designing e-textiles quilt patches reveals about CS identity work. Having so far analyzed data from three youth, we present case studies of Matthew and Layla, whose quilt patches clearly restoried dominant CS narratives surrounding identity.

Findings

Engaging in the practice of restorying through designing e-textiles quilt patches served as an ideational resource for Matthew and Layla to (1) use computing to develop counternarratives about who can participate in computing (see also Figure 1), and (2) reimagine future possibilities for participating in computing.

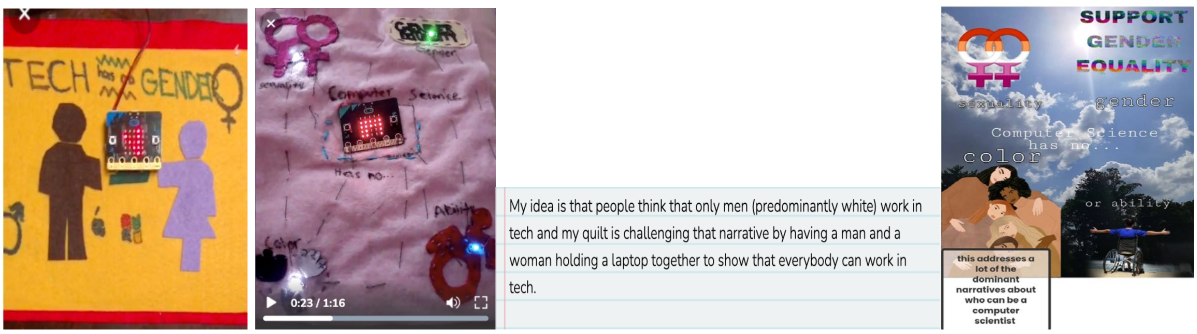

Figure 1. Screenshot of Matthew and Layla's quilt patches and reflections on the patches' themes.

Finding 1: Reimagining dominant narrative of CS as only for nerdy, white men

Restorying afforded Matthew and Layla the opportunity to both discover and reimagine dominant narratives surrounding who participates in CS. When reflecting on the kinds of people normally thought to be computer scientists, both participants identified nerdy, white men, which reflects the dominant group whose values, norms, and practices have been historically privileged within computing education (Rodriguez & Lehman, 2018). "I'm going to be honest, every time I pictured a computer scientist, I pictured some white man with glasses," Matthew admitted in his post-interview, "but now, I didn't even realize I was doing it. I didn't realize how much of a dominant narrative that was." Layla echoes this sentiment by acknowledging that no one really thinks about dominant narratives. Furthermore, they identified how CS as a discipline normalizes this dominant narrative, whether through dominant representation of white men throughout history (Matthew) or people being excluded based on their “sexuality, gender, color, and ability” (Layla). Matthew and Layla were able to tackle these dominant narratives by not only challenging how “they only show the men” as people working in tech (Matthew) but by also learning that “if I can [restory] in [CS], I can do it out in the world, I can do it at school, I can do it with friends. And I can be like, ‘This is my story, and I don't have to be excluded (Layla).” By being exposed to counternarratives that challenge the dominant white maleness of CS [e.g., through learning the stories of (mostly white) women’s role throughout the history of CS], restorying served as an ideational resource for Matthew and Layla to imagine new ways of being in CS.

It is interesting to note that while the dominant narrative Matthew critiques used an intersectional lens in addressing race and gender specifically, his quilt patch only restoried based on gender. This might reflect a limitation in the diversity of examples of female programmers we showed during the workshop, highlighting a need in future workshops to explicitly address multiple levels and intersections of oppression (across gender *and* race *and* class, etc.) throughout CS and provide counternarratives reflecting those intersections. Through restorying dominant narratives about who belongs in CS in their interactive quilt patch designs, both Matthew and Layla reimagined CS as a field more inclusive towards people, despite their race, gender, ability, and sexual orientation.

Finding 2: Reimagining present and future connections to CS

Despite having different prior interests in learning CS, the workshop provided both Matthew and Layla the opportunity to reimagine dominant narratives surrounding what CS is and the types of activities involved. At the start of the workshop, Matthew had no interest in learning CS due to assuming that CS learning environments consisted of “very boring” lectures and activities like “figuring out how to get past a firewall or something.” Further, when asked what type of student would enroll in an imaginary new CS class offered at his school, he pictured students interested in learning more about computers or pursuing a career in CS. Conversely, even though Layla was interested in learning programming prior to the workshop, like Matthew she said she would also not enroll in an imaginary new CS class offered at her school (due to being more interested in coding). She also noted that other students might fear enrolling in the class due to “the genius narrative.” These statements further reflect perceptions regarding the types of youth interested in learning CS, particularly the perception that CS courses would be attractive to students interested in more complex or *professional* authentic computing experiences (NASEM, 2021). However, after participating in the workshop, both participants expressed interest in participating in future CS workshops (if time permits) and shared that their feelings changed to seeing CS as a more artistic, intricate (Matthew), and accessible (Layla) field.

That being said, when asked whether or not they identified as computer scientists, both participants expressed identifying as computer scientists, but within limits. More specifically, Matthew identified himself as a “semi-computer scientist” but “on the artsy side, not the boring side.” Layla, on the other hand, recognized herself as computer scientist because she learned CS but on a smaller level at home where she could share what she learned with others. Restorying dominant CS narratives while designing e-textiles quilt patches also provided participants the opportunity to reimagine their future engagement with computing. Not only did Layla find the concept of interactive quilts innovative and interesting but she also appreciated learning how to program the Micro:bit, which she felt was the first step in programming a lot of other things. Furthermore, Matthew expressed that learning how to sew circuits and code his Micro:bit “enhanced [his] artist side more, by adding another style of art” (despite not seeing connections between quilting and computing in his post-interview).

Given that e-textiles prioritizes aesthetics, it provided multiple entry points for Matthew and Layla to engage in computing, whether it was Matthew’s prior sewing experience or Layla’s prior coding interest and knowledge of quilts. However, both participants noted how the CS they were doing in the workshop did not involve “going out in the world and doing these things (Layla)” or “it's not gonna be in the news or anything (Matthew).” Although exposure to materials like fabric, sensors and microcontrollers expanded their perceptions of what CS is, there still seems to be this separation between CS as a *professional* discipline that’s out in the world and the more *personal* side of CS that integrates personally relevant activities, like crafting (NASEM, 2021).

Discussion

By changing restorying from an analytical to a pedagogical framework, we provide a new approach for engaging Black, Latinx, and Indigenous youth—groups historically excluded in CS education—in discovering and challenging dominant narratives about CS while also developing their computing learning and identities. However, before bringing these activities to youth, we as researchers and educators first need to reflect on the extent to which we may be perpetuating dominant CS narratives in our own epistemologies and pedagogies. For example, by not distinguishing between “CS, the broad discipline focused on programming, computing theory, and data structures" and "computing, the designing computational devices" in our workshop, we see how Matthew and Layla associated CS learning with pursuing a career in CS, working in technology, or engaging in CS activities out in the world. Consequently, we see parameters placed on their identification as computer scientists based on their perceptions of CS done in the world (e.g., at technology companies), despite engaging in a practice of restorying the dominant ways of being, thinking, and doing in CS during the workshop. This highlights an opportunity for us as researchers to also engage in restorying by interrogating our desire for youth (particularly minoritized youth) to identify *with* the discipline as opposed to identifying as an individual leveraging computing to make transformative change [e.g., technosocial agents (Ashcraft, Eger, & Scott, 2017)]. Finally, in reflecting on the use of quilt patches in K-12 CS education, we understand that building on the history of quilts and fabric arts as media for self-expression and resistance presents a unique learning opportunity for e-textiles research. Currently, the e-textiles unit developed for the *Exploring Computer Science* curriculum includes a classroom-wide mural project where pairs of students created portions that each incorporate two switches to computationally create four lighting patterns (for more details, see Kafai & Fields, 2018). Normally themes for these murals focus on school or popular culture references; however, by leveraging the collective storytelling roots and aesthetic elements of quilting, we see potential for e-textiles quilts to serve as collaborative artifacts that reflect the CS learning experiences of youth from groups who have been historically excluded from CS. As we conceptualize what equity and inclusion means for computing education, our study hopes to expand minoritized youth's computing practices to involve critical interrogation of the discipline as well as speculative practice to reimagine computing as a tool for social transformation.

Computational Art Ecologies

Gabriella Anton, Uri Wilensky
gabriella.anton@u.northwestern.edu, uri.wilensky@northwestern.edu
Northwestern University

Abstract: We argue for a broader approach to understanding computational thinking that decentralizes CT from the definitions in CS and STEM and works toward authentic definitions in other fields. We contribute to this scholarship by exploring the intersection of computational thinking and art. While there have been myriad successes in creative computing initiatives in education, there has been little research to characterize the authentic computational practices in art fields. We propose a new theoretical frame, *computational art ecologies*–based on Dewey's theory of art as experience–which can be used to capture and visualize an artist's relationship to computation and art. We introduce two cases of computational artists within this theoretical frame and highlight the differences in their relationships to these fields of practice.

Introduction

Within K-12 education, initiatives to teach computational thinking have largely been aligned with computer science (CS), and more recently science and mathematics (Grover & Pea, 2013). While important for providing exposure to authentic skills and practices, the alignment with CS and STEM constrains the epistemologies and perspectives that learners can bring to their explorations in computing (Kafai, Proctor, Lui, 2019; Harell, 2013). We argue for a broader approach to understanding computational thinking that decentralizes CT from the definitions in CS and STEM and works toward authentic definitions in other fields. We seek to contribute to this scholarship by exploring the intersection of computational thinking and art. In this paper, we propose a new theoretical frame, *computational art ecologies*–based on Dewey's theory of art as experience–which can be used to capture and visualize an artist's relationship to computation and art. We introduce two cases of computational artists within this theoretical frame and highlight the differences in their relationships to these fields of practice.

Creative computing and computational art

Scholars in computational fields have a rich history of designing educational programming that leverages creative and artistic practices. Youth-friendly programming languages often focus on digital media creation (Resnick et al., 2009). Similarly, studies of youth designing and developing their own games have showed gains in a wealth of creative and artistic practices, literacy, and critical thinking practices (Peppler, 2010). Constructionist scholars have advocated for interdisciplinary computational learning environments, shown to be successful in engaging children in deep thinking while sparking new creative epistemologies (Eisenberg, 2003; Sendova, 2001). To support learners in gaining the authentic computational practices seen in art, like those constructing situated definitions of CT in other fields (Weintrop et al., 2016), additional work needs to be done in capturing the computational practices and perspectives that appear when engaging in artistic practice.

We turn to literature on visual art to better understand authentic computational practice. One of the characteristic perceptions of twentieth-century art is its persistent tendency to question the tradition of painting as the privileged medium of representation (Rush, 2005). As art is a highly expressive and reflective practice, advances in technologies are often mirrored in artistic ventures. Artists who practice with computation or technology will explore and often subvert both the critical and technological potentials of new media (Rush, 2005). Computational methods add new elements to the artist and user experience, including potential for interaction with the viewer, additional sensory features, and expanded temporality (Wands, 2006).

There is has been little research on the role and use of computation in the art process. Early research in this vein highlights the integration of technology in the lives of artists but focuses more on the day-to-day impact rather than on how it changes art expression (Beardon et al., 1997). In this work, we extend the scholarship within CT education and art to explore the intersection of the two fields. Like those who extended CT definitions into STEM fields, we argue for the need for observation and study of experts to construct definitions of computation in art that are reflective of authentic practices and perspectives within the field (Wilensky, Brady, Horn, 2014; Weintrop et al., 2016). We interview artists who self-identified themselves as using technology or computation in their practice to begin to capture the computational perspectives and practices that are valued within the art field.

Methodology

Theoretical lens: Computational art ecologies

We extend Dewey's theories of art as experience and art ecologies to conceptualize how artists experience computation in their art practice (1934). Dewey attempts to shift the perception of art away from focus on a product. Instead, he argues that art is a process that is reflective of social and cultural experience. We leverage Dewey's theory to construct a simpler model of an ecology that can holistically capture the unique agents, institutions, and factors relevant to each singular artist, as not all are participating in the same type of art world. As such, we propose the use of *computational art ecologies* to capture the factors that impact an artist during the creation of a piece of computational artwork (see Figure 1). In this model, nodes reflect the artist, the audience, computing and art fields, and the artwork. These are situated in a broader sociocultural and historical context that impacts both the artist and the audience. The connections can be weighted to reflect stronger influences between nodes, while the nodes themselves can be added or removed to reflect unique ecologies for a given artist.

Participants, data, and analysis

Artists were recruited through cold contact to participate in an interview on their use of computational tools and practices in their artwork. A total of 9 artists were interviewed by the first author (6F, 3M). For this paper, we identified two artists, both female, who leverage different mediums and computational approaches to present cases of art ecologies. These were selected based on post-interview memos to capture contrasting cases. Janell Baxter waived anonymity. Alex is a pseudonym. Interviews were sixty to ninety minutes in length and asked into the artist's experience with and perception of art and computing. Interviews were coded with thematic codes derived from the *computational art ecology* model. We coded interview episodes for the artist's *relationship with computing*, *relationship with art*, *relationship with audience*, and the *intersection between art and computing*, reflecting the connections between key nodes in the model (see Figure 1). In each coded episode, emergent themes were qualitatively described and then synthesized across these sections.

Results

In the following two cases, we summarize two artists' experiences with and perceptions of computation in their personal art practice. Finally, we compare the ecology for each artist to suggest ways in which these two cases differ in meaningful engagement with computation.

Janell: Case of self-reflection

Janell Baxter is faculty at Columbia College in Chicago and Associate Chair of the Interactive Arts and Media Department (IAM). She describes herself as "exploring the synergies between programming, design, and art" in her bio. Janell has focused much of her artistic practice on the creation of generative art bots. She programs these artificially intelligent bots to generate their own artwork after interpreting libraries' visual or textual artifacts. She has created over 13 versions of these bots since her first show in the late 90's.

Surveying Janell's computational art ecology

Relationship with art. Janell expressed an early interest in art that continued throughout her undergraduate studies, where she obtained a Bachelor of Fine Arts in Studio Art. She went into art "to express [herself] and to communicate…it was a sort of therapeutic way of working through issues with artwork." The time she spent in her studio arts program shaped her approach for thinking about programming and computation, namely in directing focus on "concepts" rather than technique. For Janell, her art practice appears to be personally reflective and expressive, helping her to make sense of both internal and external factors that emotionally impact her.

Relationship with computing. Janell expressed a rich relationship with computing that started when she was a young girl. She opened by telling a story of attending an early punch card computing course with her mother, described with religious language, that sparked her curiosity and awe around the "mystery" of computation. After finishing her undergraduate, she went to graduate school at the University of Chicago for computer science, where she studied CS in a program with a rigorous mathematics focus. She reflected on the difficulty she had in connecting with the framing of the program, mentioning the focus was on goals traditionally associated with computer science (e.g. efficiency, algorithms) and that the "human" perspective was missing in the education. For her, the practices and skills learned were vital, but she needed to spend a lot of time independently to contextualize these practices in her own ethical and moral perspective of society. This self-reflection carries into her art practice.

Intersection of art and computation. Janell's conception of art and computation are strongly tied, with her focus on the practice of creation and programming as the output. She began her bot series after an invitation to an art show on the theme of the 'goddess.' As she explained, "in trying to figure out how to addresses idea of goddess, I sort of became like a God in that form. And I made something that would then make something and that's how I could connect to it." In this show, she displayed her code in a book on a pedestal, almost like a holy book. Throughout her practice, she has maintained the perspective that her code is the art. Others have critiqued or expressed confusion about her work, saying, '"Oh, well the code is just a tool, or the computer is just a tool." Or, you know, "this part of your medium, like the code is your medium."' She reflected on this, saying, "And I was thinking well, but no, the code is the thing that I'm really interested in."

Relationship with the audience. Janell's practice is heavily self-motivated. Her purpose for creating artwork translates into her relationship with the audience, in that she creates these bots for herself with no desires or attempts to sell them. The shows she has participated in have largely been to reach professional goals. The artwork itself, the code, has always been prominently shown and the artwork of the bots, the generated art, put on display so the audience could connect with something. She likens her practice to Buddhist monks creating sand mandalas: "You see those people who make those very intricate, amazing sand designs, and then they sweep it away…like let's write the code and run the code and then it's done kind of a thing. And it can kind of go away because it just bringing it into existence in me thinking about that."

Alex: Case of critiquing technology

Alex is an artist using video, sculpture, and performance to explore questions around technology, identity, and labor. Alex is formerly from the tech industry and currently a master's student in fine arts. Alex's art focuses on a critique of technology, primarily around the social and cultural biases throughout the tech industry. Her work leverages myriad tools and mediums to critique these constructs. For example, in one series, Alex whether technology could take on identity. She created sculptures that were each a functioning battery made with copper and zinc electrodes, blood, and simple electronic components.

Surveying Alex's computational art ecology

Relationship with art. Alex spent most of her childhood engaging in artistic practices like drawing and painting. Professionally, she did not consider art until after her undergraduate program and experience in the tech industry. She attended a hybrid school focusing on the intersection of code, design, hardware, and theory. Despite attending with the goal of gaining more programming and computation skills, she began to realize her identity as an artist. She describes her motivation throughout her art as "critiquing the tech industry".

Relationship with computing. Alex's interest in computation started when she was in undergrad, focusing on the ways new technologies could be leveraged for social mobilization and other political practices. After graduating, she moved into the technology sector but quickly became "disillusioned…with how these technologies are being created." She spent several years teaching herself programming before attending an interdisciplinary school for art and computation. Alex's critique of the tech industry uses computational traditional materials and mediums to draw out the biases and inequalities within the field. She mentions that she "[uses] technology as intended, [with the] critique coming from the way it is used, opposed to using it itself."

Intersection of art and computation. Despite engaging deeply in conversations of technology and participating professionally in computing fields, Alex sees herself as an outsider in computational art. In her perception of the field, there are some artists using cutting edge or immersive technologies and others who engage in building or subverting tools, and she sees herself as external to both camps. She views technology as another tool that she can leverage when it best fits the purpose and critique of a given project. Ultimately, she remains conflicted on her use of computation, stating: "If you told me you're never allowed to use technology again in your art, I would be like, okay, I can figure that out. I guess that's a little sad, but it's okay."

Relationship with the audience. Alex's goal is to start a discussion or conversation about technology rather than focusing on the technology itself. As such, she spends considerable time reflecting on how technology will interact with and impact her audience to engage in the underlying message most deeply. Beyond the audience of laypeople, she struggles with situating herself in computing and art fields, reflecting people in the tech industry or tech artists are not very impressed with her artwork since "it is not very complicated or flashy or interesting."

Computational art ecologies

Both Janell's and Alex's work with computational art focuses on themes of humanity within computation. Within their critical reflection of how computation impacts social and cultural contexts, we see differing practices and goals emerge while creating artwork. Two key differences are the centrality of computational practices in the creation of artwork and the intended relationship with the audience. Based on their coded interviews, we identified unique art ecology models for each artist to visualize these differences (see Figure 1).

Janell uses art as a process for self-reflection and expression, so we strengthen the arrow connecting her to her art node. Her engagement in technology appears to support her understanding and exploration of theories and assumptions about social and cultural contexts. We make a one-directional arrow towards the computing node and add an arrow leading from computing into the broader sociocultural, historical context. Her experiences with art and computing are closely tied, and she sees the code or the bots as the true artwork. As such, these nodes are clustered. Finally, Janell's audience interacts primarily with art her bots create, and Janell explicitly denied her ownership of this generated art. We add a node for the bots' artwork and a dashed line to denote the diminished importance of audience interaction for Janell.

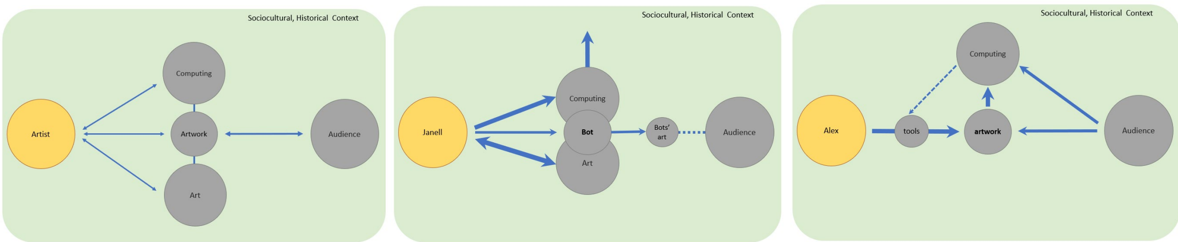

Figure 1. On left, a model of a computational art ecology. In middle, the art ecology for Janell. On right, the art ecology for Alex.

Alex uses her art to openly critique computational fields. She places focus on the artwork and leverages a variety of tools, both traditional and computational, to accomplish her goals. As such, there is a one-directional weighted arrow between her and her artwork node. We add a node for tools, reflecting the importance of this selection in her art process. A one-directional arrow leads from her artwork to the computing node, and a dashed arrow leads from computing to tools, to highlight the occasional use of computational tools. Lastly, Alex seeks to spark discussion and reflection of technological practices within her audience; arrows connecting the audience node to the artwork and computing nodes can be seen.

Discussion and Conclusion

Through analysis of two cases, we identified unique *computational art ecologies* that capture differing relationships with computation and art. Computational art ecologies are flexible models that can be easily manipulated through the addition or subtraction of arrows or nodes to reflect the unique experiences of a given artist. We found that the application of these models to Janell and Alex highlighted differences in their engagement with computation in their artwork. Between the two artists presented here, we already see gaps to explore for CT education. Future work will apply this methodology to all artists within the larger sample and generate thematic patterns across these relationships. This may be useful in characterizing emergent "types" of computational artists. We believe these models of art ecologies can support a richer conceptualization of computational thinking in art that can then be translated to education as authentic practices, especially as we work to characterize and build out a landscape of computational practices, perspectives, and goals unique to this space.

Language, Modeling and Power: A Methodology for Analyzing Discourse in Interaction

Maximilian K. Sherard, The University of Texas at Austin, mksherard@utexas.edu
Anthony J. Petrosino, Southern Methodist University, ajpetrosino@smu.edu

Abstract: We present a new methodology for demonstrating the connection between reasoning in interaction and larger sociopolitical discourses. We demonstrate this methodology in the context of modeling activities with preservice teachers. First, we explain critical discourse analysis, a methodology which illuminates how talk or text in social events is related to larger social practices or structures. Second, we describe how using critical discourse analysis with interaction data allows researchers to understand how language choices reflect larger discourses that circulate society. Finally, we demonstrate this methodology on a transcript of preservice elementary teachers reasoning about residential segregation using agent-based models.

Introduction

Models and modeling are a cornerstone of scientific practice (Giere, 2004; Lesh, Doerr, Carmona, & Hjalmarson, 2003). Scholarship in the learning sciences have studied modeling in a variety of ways influenced by cognitive perspectives on learning (Knoespel, 1999). Furthermore, a number of pedagogical tools have been developed to support teaching and learning with models. One such technology we explore in our own work has been the use of NetLogo models for developing preservice teachers' understandings of complex phenomena (Wilensky, 1999). However, the learning sciences are expanding. Now more than ever, our community is finding new ways to address political aspects of learning to compliment the cognitive, social, and cultural perspectives already well developed (Esmonde & Booker, 2016; The Politics of Learning Writing Collective, 2017). Our aim in this paper is to offer a new methodology for analyzing how sociopolitical discourses mediate reasoning and learning in the context of modeling. Specifically, we hope to add critical discourse analysis (CDA) as a tool for the learning sciences. In this paper we summarize CDA and select some techniques for applying it to interactional data. We close by demonstrating this analysis with an example from video data of preservice elementary teachers using agent-based models to learn about residential segregation.

Critical discourse analysis for the learning sciences

Discourse analysis techniques are widely used in the learning sciences, especially in interactional studies of learning (Greeno, 2006). CDA is one such technique, based on systemic functional linguistics (Halliday, 1978) which aims to understand how talk in interaction or written texts are shaped by sociopolitical discourses which circulate society (Fairclough, 2003; van Leeuwen, 1993). Fairclough defines sociopolitical discourses as relatively stable ways of representing the social world with language. For example, van Leeuwen examines how pro-nationalism discourses influence language choices in news articles about immigration (1996).

CDA scholars have developed a wide range of sophisticated techniques, adapted to different disciplines (communication and media studies, political science, etc.), which demonstrate the connection between talk and discourses. In this article we focus on one technique: the representation of social actors through talk. Social actors are any participant from the real world which are referenced in talk and capable of carrying out actions. They are typically indexed with nouns or pronouns. Social actors can be individual people, collections of people, institutions, or even ideas/objects. We can identify discourses by determining patterns in how people include and relate social actors as they speak. We find this aspect useful to analyze learning with models for two reasons. First, modeling is inherently a process of selecting, amplifying, and reducing aspects of the real world. For example, NetLogo models represent actors from the real world as agents or "turtles". Therefore, patterns in what is selected, amplified, and reduced are likely to be mediated by discourses, especially for models which relate to social phenomenon. Second, when learners modify models, we can observe changes to how they represent social actors and use these changes to understand how sociopolitical discourses relate to their reasoning about complex phenomenon. In the next section, we discuss in detail our method for applying CDA to interactional data.

Using critical discourse analysis with interactional data

To understand how political discourses influence reasoning we must closely examine talk in interaction (Greeno, 2006). First, we describe how to create transcripts which highlight the representation of social actors whether they are spoken about, gestured to, or referenced in artifacts. Then, we discuss two analytical aspects that can illuminate how social actors are represented and which political discourses shape these representations.

Generating transcripts of interaction data for CDA

Critical discourse analysis has typically been used to analyze text produced written *about* social events. For example, many CDA scholars examine news media articles. These forms of data are ripe for CDA because analysts can focus solely on information included (or excluded) by the author. Similar to texts, when people talk, they also represent the social world. Distinct from texts, talk in interaction is multi-modal, and includes actions of the individual, interactions with other individuals, and interactions with the environment. Therefore, the representation of social actors cannot be analyzed by only paying attention the words spoken. Instead, analysts must pay attention to the talk and gesture of the individuals, interactions between the individuals, and references to aspects of the environment. To capture the representation of social actors distributed across these areas, we create transcripts which vertically organize chronological interaction, and horizontally organize categorical information (Figure 1). This transcript method allows researchers to identify social actors whether they are referenced in talk, gestured to, or present in the environment.

Time	Participant [direction]	Talk	Video Still	Environment Still
Hr. Min. Sec.	Name of participant [who utterance was directed at]	Transcribed text Short Pause (..) Long Pause (...) ((gestures)) [reference to environment] *Notes from transcriber*	[still selected from video record, typically demonstrates a gesture or reference to proximal environment]	[photograph of important references from proximal environment]

Figure 1. Sections of the transcript for deploying representational analysis

Analyzing social actors for inclusion and activation

Once transcripts have been generated, we then identify which social actors represented. To do this, we read the transcripts while watching video footage and pay attention to any nouns or pronouns which conduct actions or receive actions. By conducting or receiving actions, we are referring to the verbs used within sentences. Once a list of social actors has been determined, we bold these in the transcript to proceed with closer analysis.

While there are a number of ways to proceed with closer analysis, we draw on two concepts related to the representation of social actors: (a) *inclusion* or *exclusion* of social actors; and (b) *activation* or *passivation* of social actors. When individuals talk, they select certain social actors from the social world to discuss and (intentionally or accidentally) ignore others. CDA scholars refer to this process as the *inclusion or exclusion of social actors*. For instance, in the clause "protesters were arrested last week": protestors are the only social actor which are included. Those who arrest the protestors, in this example, are excluded. Related to inclusion, participants or social actors can either be *activated* or *passivated.* For example, protestors are passivated in the above example (they were arrested), and the excluded participant (police) are activated (as the individuals responsible for making arrests).

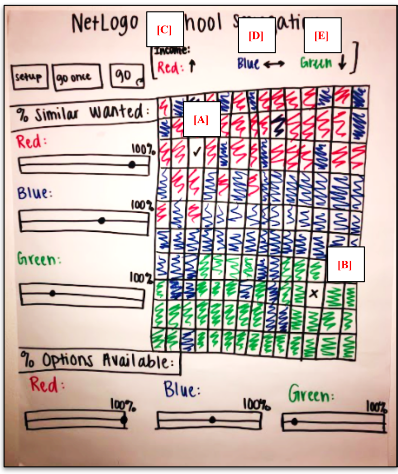
By examining patterns in inclusion/exclusion and activation/passivation of social actors, we can begin to see the way power is distributed with language as people reasoning through complex phenomenon with models. By making comparisons between different groups of people and how they include and activate social actors, we can witness how competing sociopolitical discourses relate to talk in interaction. In the next section, we demonstrate these techniques with interactional data, but save cross-group comparisons for future work.

Example: Preservice elementary teachers reasoning about segregation

Modeling as a practice involves reducing a complex phenomenon for the purpose of understanding and prediction (Lehrer & Schauble, 2000). Probing *how* the complex world is reduced then, provides insight into the way sociopolitical discourses mediate reasoning. The data we analyze here was selected from a 2-lesson modeling exercise with 16-preservice elementary teachers enrolled in a science methods course. Participants engaged in the modeling unit to use, evaluate, and modify a NetLogo model designed to simulate causes of residential segregation (Wilensky, 1997). We selected residential segregation because it is a complex phenomenon which clearly intersects with issues of power. Below we discuss the transcription and analysis of interactional data.

Generating the transcript identifying the social actors

The 2-lesson series was video recorded with a resulting 6-hours of video tapes to be reviewed. We also collected participants' final modification to the NetLogo model (in the form of a drawn schematic on a sheet of poster paper). CDA is too time intensive and complex for such a large corpus of data. Therefore, we decide to focus analysis on the last activity where participants presented their final modification of the NetLogo segregation model to the class. We chose this portion of the lesson series to analyze because participants will necessarily discuss and relate social actors in ways that will illuminate specific sociopolitical discourses. Below we include a photograph of the participants' modified NetLogo model (Figure 2) and an excerpt of the transcript from their presentation. (Table 1). We exclude images of the students talking for privacy purposes.



Social Actors referenced from Model Diagram in Talk:

[A] Good School
- Represented as "✓"
- Located at top of model
- Have more available resources/school funding

[B] Bad School
- Represented as "x"
- Located at bottom of model
- Have less available resources/school funding

[C] High Income Homes
- Represented with red shading
- Have highest "% similar wanted"
- Have highest "options available"

[D] Medium Income Homes
- Represented with blue shading
- Have middle "% similar wanted"
- Have middle "options available"

[E] Low Income Homes
- Represented with green shading
- Have lowest "% similar wanted"
- Have lowest "options available"

Figure 2. A modified NetLogo segregation model presented by three participants. Notes provided on the right-hand side were added by the researchers.

Table 1: Excerpt of transcript for two students presenting their modified NetLogo model

01:12:26	Sage [to class]	Okay so in this NetLogo there is a ((gestures to the top of the model)) [A] considered a **good school** ((uses air quotes around good school)) and there ((gestures to bottom of the model)) [B] is a **bad school**.. Just based on available materials and I guess school funding. So then we made three **turtles** based on household income. The **red** ((gestures to top of model where phrase "red ^" is written)) [C] is high income. The **blue** ((gestures back and forth with hands)) is medium [D]. And **green** low income [E]. And also, we didn't leave any space because in a perfect world, **everyone** has a household.
01:13:03	Bree [to class]	Okay so we basically did like.. the percent similar wanted was ((gestures to three percent similar wanted sliders)) like pretty similar to our regular one. So like the **red people** ((gestures to the red percent similar bar)) wanted to stay mostly around red but allowed for some blue. The **blue** would stay mostly around blue but would prefer maybe more red. And then **green** is like wherever they can.

Analyzing social actors for inclusion and activation

First, we identify which social actors are included in the interactional sequence. To do this, we recursively view the video footage, read the transcript (looking for nouns or pronouns which conduct actions), and cross reference the transcript with the artifact (Figure 2). We de-emphasize personal pronouns (we, I, us, etc.) and instead focus on those related to the model. In this excerpt, we see five important social actors emerging: (1) good school, (2) bad school, (3) high-income homes, (4) middle-income homes, and (5) low-income homes. These social actors are represented in the modified model symbolically, gestured to as students talk, and are bolded in the transcript to make them more noticeable. To examine excluded social actors, we can either: (a) compare this model with the original NetLogo model which included two social actors (red-homes and green-homes), representative of two racial groups; or, (b) compare this model with other models created by different groups of students from the class. Despite engaging in a 2-lesson series about modeling the causes of residential racial segregation, this group of students exclude race from their final modified NetLogo model and instead include socioeconomic status and schools.

Following analysis of the inclusion and exclusion of social actors, we can investigate how these social actors are activated or passivated with relation to the verbs. The social actors "good school" and "bad school" are both hypothetical institutions gestured to and represented symbolically in the model. They are first activated with the verb "is" signifying that they simply exist in the modified model. Both the good school and the bad school are mentioned with the gestured air quotes, which may indicate the speaker is acknowledging some fallacy in the categorization of schools. However, Sage then activates both the good school and bad school with a relational verb phrase "just based on" and mentions two qualities that make the school "good" and "bad": available materials and school funding.

The second group of social actors represented in this model and transcript are individual households in the simulation. First, Sage mentions the social actor "turtle" (a NetLogo term referring to any agent used in the model) and activates this social actor with the relational verb "is based on household income." Therefore, we know that households will be separated broadly into income groups. She follows this statement by naming three sub-classes of household and activating each of them with relational verbs. She activates red turtles with "is high income" and blue turtles with "is medium" (income). For the green turtles, she does not use a verb, but the verb is implied from the sentences before it, and the green turtles are activated as "low income" households.
Bree then steps in to further explain how these three social actors can behave in the modified NetLogo model. Bree activates the high-income social actors with two behavioral verbal phrases: "wants to stay mostly around red" and "but allowed for some blue." Bree activates middle-income social actors with two behavioral verbal phrases: "would stay mostly around blue" and "would prefer maybe more red." Finally, Bree activates low-income households with the behavioral verbal phrase "is like wherever they can." While none of these actors are passivated, they are activated with different amounts of power because of the verbs that are used with them. First, high-income and middle-income social actors are represented as having preferences for where they would like to live; whereas, low-income social actors are represented as moving "wherever they can."

Discussion

Here, we analyzed a single group's representation of social actors using two CDA tools: inclusion and activation. Already, we can begin to see the contours of sociopolitical discourses that mediate how they understand segregation. For example, schools are either good or bad based on the amount of resources they have, and only high and middle-income households have preferences for who they live near. The power in this method is amplified when comparisons are made between spoken or written text during different events. For example, examining how other groups in the class model and discuss the same phenomenon, we can begin to notice similar or competing sociopolitical discourses which mediate students reasoning.

Abstract: Despite widespread and concerted efforts, women and people of color are still dramatically underrepresented in STEM fields. Research in this area suggests the oppressive cultures surrounding STEM are one reason for the disparities in STEM participation across social categories. Cultivating counterspaces in STEM for girls and Black and LatinX learners continues to be critical, especially in the current moment when the vast majority of learning activities have shifted online. In this study, we examine an out-of-school time STEAM learning program designed for Black and Latina middle school girls to better understand how community and relationships can persist as the learning landscape shifts from in-person to online due to a global pandemic. We argue that counterspaces are critical to understanding why supportive community is necessary for Black and Latina girls particularly.

Introduction

Despite widespread and concerted efforts, women and people of color are still dramatically underrepresented in science, technology, engineering, and mathematics (STEM) careers (Corbett & Hill, 2015). Overall, much of the research in this area suggests that differences in STEM participation across social categories are likely due to the nature of the cultures surrounding STEM (Ong, Smith, & Ko, 2017). Cultivating communities and cultures in STEM that value diverse voices and that are open to shift and change along with members' needs is critical (e.g., Margolis, et al., 2008). Even in the midst of a public health pandemic (i.e., COVID-19) that has shifted the global and educational landscape, it is still vital to engage in both community-building and creating inclusive counterspaces. As program designers of a STEAM program for girls, we, like many others, had to quickly shift our in-person efforts to build culture and community in STEM to the virtual space, requiring us to redesign our activities, social practices, and expectations for interaction. However, as the landscape of in-person and remote learning is still shifting, it is not yet known how these two spaces interact and how the changes impact community and cultures in STEM learning.

Thus, we explore the following research question: How can community and relationships for middle school girls in an out-of-school-time (OST) STEAM learning program persist during a sudden shift to online learning? In this study, we describe our efforts to continue Digital Youth Divas (DYD), an OST program that aims to engage middle school girls, especially those who identify as Black and Latina, in design-based STEAM and computing activities (Pinkard et al., 2017). Our findings have implications for educators, researchers, and program designers as they seek to understand the importance of community and relationship building and develop interventions or strategies to build community in both online and in-person learning programs.

Background and theory

Our work takes a sociocultural perspective of learning (e.g., Lave & Wenger, 1991), understanding that learning happens through participation in communities. We also view learning as taking place dynamically across contexts such as home, school, and community through interactions with peers and adults (Barron, 2006). Studying an OST STEAM program like DYD, we acknowledge the importance of and intentionally aim to engage two groups in girls' learning ecosystems: parents and mentors. Prior research suggests family involvement in OST settings benefits academic performance and program retention (Deschenes et al., 2010). Furthermore, parents' interests, knowledge, and values influence youth's computing and technology learning and expertise (Barron et al., 2009).

In oppressive STEM climates, girls' lack of sense of belonging and a shortage of mentoring appear to be instrumental in women's decisions to leave STEM (Fabert, et al., 2011), particularly those who face gendered racism (Thomas et al., 2018). Mentoring programs, especially those engaging near-peer mentors have helped students develop an interest in STEM, positive STEM identities, a sense of belonging in the community, and the will to persist in academic STEM journeys (Zaniewski & Reinholz, 2016). Further, same-gender peer mentoring increased mentees' confidence, motivation, sense of belonging, and retention (Dennehy & Dasgupta, 2017).

In addition to parent and mentor support, a crucial factor impacting Black and Latina girls' participation in STEM is the underlying culture of STEM itself. STEM cultures and communities are often built on practices typically associated with stereotypical white and hypermasculine ways of being (Simon, Wagner, & Killion, 2016). As such, learners who do not identify with these ways of being may feel that their full, authentic selves are unwelcome or must be changed in order to participate in STEM (Thomas et. al, 2018). Thus, it is necessary to create counterspaces, or safe spaces where Black and Latina learners can grow, learn, and be in community with others (Ong et al., 2017). These counterspaces can form in different ways and do work to alleviate negative impacts from oppressive structures and cultures created by negative stereotypes and deficit narratives (Ong et al., 2017). In the current study, we seek to create a counterspace by providing inclusive, welcoming spaces for Black and Latina girls and their families to engage in STEM learning.

Methods

Program description

DYD is a program created to engage Black and Latina middle school girls in design-based STEAM and computing projects that are introduced by narrative stories (Pinkard et al., 2017). Since its inception in 2013, DYD has had over 500 girls participate and trained over 40 high school, undergraduate, and graduate students to be near-peer mentors. Led by the near-peer mentors, each session involves hands-on learning experiences designed to make connections between STEM and girls' own interests, such as art, fashion, or music. To build community in and beyond the DYD, the girls' parents and caring adults participate in workshops and social events designed to support family engagement in STEAM called Caring Adult Network (CAN).

Participants

During the program year 2019-2020, a total of 47 girls between ages 10 and 12 in a midsized racially and socioeconomically diverse community joined in the 16-week program. Parents of the girls were racially diverse, where approximately 30% identified as African American, 26.42% Latino/a/x or Hispanic, 11.32% Caribbean Islander, 11.32% White (non-Hispanic), 9.43% Asian American, and 11.32% other (Biracial, Jewish, Asian Latino, Native American, American Indian, or Alaskan Native). Household incomes were also diverse, with 27.66% between \$20k -\$50k, 21.28% between \$60k - \$100k, 27.66% between \$100k - \$150k, and 19.15% making \$150k or more.

Data sources and analysis

We distributed a post-program survey among youth participants to understand their experience in and beyond DYD, asking questions such as *How much do you feel supported by your mentors?* Activities were facilitated through an online learning platform; through this, we were able to collect attendance and participation data even while engaging in remote learning. We also distributed a post-program survey among parents to collect feedback on their experience in DYD and CAN as well as the impact of COVID-19 on their families. We observed and recorded the final program showcase event with a focus on the experience and relationship between the mentors and the girls. In this paper, we present preliminary results that describe the ways families, mentors, and girls built counterspaces and a supportive community in-person and virtually.

Preliminary results

We provide preliminary results from this work by briefly describing changes we made to accommodate the shift to online programming, sharing the extensive impact of COVID-19 on the families, and sharing reflections on the program from parents and youth participants.

Programmatic shifts

When faced with a required lockdown due to the COVID-19 pandemic, we made use of the online video platform Zoom, in lieu of our in-person sessions, workshops, and events for both girls and parents and caring adults in CAN. The scheduling of DYD sessions remained on the same day and time to encourage girls to stay engaged and connected as the pandemic began. We used breakout rooms, online quiz and game websites, virtual whiteboards, and other online resources to create fun and interactive learning experiences during the Zoom sessions. We also invited girls to connect with their peers and program mentors via weekly social Zoom sessions to chat about their DYD projects and life in general. We scheduled two CAN events for parents during this time; one was an online chat to discuss supporting families, and the other was a final showcase. We also communicated with families more often, incorporating SMS and phone calls in addition to emails (Coleman et al., 2021).

Impact of the pandemic on families
Participation in DYD in the year 2019-2020 could not be fully understood without accounting for the impact the COVID-19 pandemic had on families. Parents and caring adults reported a significantly negative impact on their daily lives due to the COVID-19 pandemic, indicating that bandwidth was stretched incredibly thin for families during this time. In the post-survey, we asked parents, "What impact did the COVID-19 pandemic have on you and your family?" All respondents reported at least one negative impact of COVID-19. Of the 26 respondents, 18 reported difficulty transitioning to remote learning for DYD, 16 reported difficulty transitioning to remote learning for school or work, and 10 reported an immediate negative economic impact due to COVID-19. This clearly indicates that DYD families were deeply impacted by the pandemic and reminds educators and researchers the importance of moving forward with open understanding.

Responses to the program
The programmatic shifts, in addition to the larger pandemic context, impacted attendance for both DYD workshops and CAN events. The average attendance at youth sessions and CAN events did drop significantly after the shift to virtual programming. However, the impact of the programming and the quality of participation remained high. Evidence from the workshops, parent, and youth surveys indicates that DYD was overall an important part of the families' lives and continued to play a positive role in learning and socialization. For example, in an open-response question that asked parents to comment on the program and the impact of the pandemic, one parent responded, *"Thank you for doing the program, I would not be able on my own to expose my child to the STEM topics and activities in addition to the role models."* Another parent described that their child looked forward to every Zoom session, missed seeing her friends in person, and attended every event possible. This parent concluded, *"Doing the online meetings on Saturday brought a sense of normalcy to this chaotic situation."* Similarly, in the post-program youth survey, the majority of girls indicated that they felt like they belonged in the DYD community. Together, these responses suggest that DYD remained a safe space and a positive influence for the girls and families who were able to continue participating.

Importantly, the care and effort put forth by the mentors to create a safe and supportive space for the girls can be seen in the way they structured the final showcase event of the program year. Mentors made personalized videos for each of the girls who attended the final showcase, congratulating them on a year of growth and learning, and taking time to point out things they appreciated about each one. The mentors publicly shared personal sentiments such as *"I loved your positivity and your kindness."*; *"I really enjoyed how quick you were to adapt."*; and *"...I really liked your enthusiasm..."* These affirmations demonstrate that building community throughout DYD meant focusing on personal growth, social and emotional support, and individual connections. In the post-program survey, the girls generally indicated that they felt supported by their mentors. This demonstrates that even remotely, a community can be built and sustained for Black and Latina girls by focusing not only on STEAM learning but also on validating girls' emotions and experiences and explicitly praising their efforts and persistence.

Reflections and implications
Our study examined the implementation of DYD as learning activities shifted to virtual spaces due to COVID-19 and how culture and community could be built and sustained around STEM for Black and Latina girls in particular. While we cannot know the impact the pandemic had on program participation of other demographics as compared to our participants and their families without comparative study, we acknowledge that large-scale crises tend to make more visible existing structural inequities that impact Black and Brown communities (Sequist, 2020). While we needed to make decisions quickly about how to organize our program in response to the pandemic, we could not know all the ways the crisis would impact families' ability to participate. Even now, much is still unknown about the constraints and opportunities faced by our diverse population of families.

These initial findings provide lessons to build on as we continue establishing online community connections for 2020-2021. First, a supportive community must be willing to adapt and shift to members' needs, while also not placing blame or fault on families for situations beyond anyone's control. While at first glance the downward trend in attendance may seem disappointing, it serves as a reminder that families may have competing demands on time and energy, resource constraints, or other concerns that may impact their ability to prioritize OST STEM learning. Strategies such as more frequent contact with families through multiple communication modes should be designed to meet girls' and their families' needs and preferences. Next, much like the DYD mentors gave the girls words of praise and encouragement in the final showcase, a mentoring relationship that provides a STEM counterspace must highlight and celebrate the full, authentic selves of the learners and validate both their STEM interests and other aspects of their identities. Last, we acknowledge that community and counterspace building takes intentional work and time, and may be even more challenging online. Understanding what families have gone through during the pandemic helps us design a better experience for all families while remaining mindful of our program mission. Educators should adopt an ethic of care now and always and continue to commit to providing counterspaces for learners who are too often subjected to gendered racism in STEM and computing. Future work should also further examine the role of race, ethnicity, class, and other factors on families' abilities to thrive and learn during crises.

Caregivers' Role-taking during the Use of Discussion Prompts in At-Home Engineering Kits

Soo Hyeon Kim, Indiana University-Purdue University Indianapolis, skim541@iu.edu
Jungsun Kim, Indiana University Bloomington, jk153@iu.edu

Abstract: This study presents a video-based case study of families who used discussion prompts in the at-home engineering kits. We examine different roles that caregivers took on during the implementation of the prompts to organize families' engineering learning activities. Narrative accounts and transcriptions were analyzed to investigate the different roles that caregivers took. Three roles emerged: caregivers as *monitor*; caregivers as *mentor*; caregivers as *partner*. We further coded families' talks to investigate how three different caregivers' roles influenced families' engineering practices and caregiver-child talk types. Preliminary findings illustrate how three caregivers' roles enabled and constrained different types of engineering practices and caregiver-child talk types. Findings contribute to future considerations in designing discussion prompts for at-home engineering kits.

In response to COVID-19 pandemic, caregivers' engagement in their children's learning is an emerging priority. We provided at-home engineering kits, which included open-ended engineering challenges and discussion prompts to facilitate families' engagement in engineering practices at home. While research has examined the role of prompts in informal learning settings (e.g., Zimmerman, McKinley, Kim, & Grills, 2019), most studies are from contexts where facilitator support is available; less is known about how prompts can support caregivers to guide children's' learning at home. In this paper, we examine different roles that caregivers took on during the implementation of the discussion prompts to organize families' engineering learning activities.

Theoretical framework

We focus on families' social interaction and conversations by building on work that applies sociocultural theories to family learning (Dierking & Falk, 1994). In families' shared activity, caregivers can take on roles to structure families' participation and support negotiation of meanings (Rogoff, 2003). Prior research suggests that caregivers take on roles such as teachers, collaborators, and learning brokers (Barron, Martin, Takeuchi, & Fithian, 2009). Our conjecture is that caregivers' roles influence the degree of structure and formalness when using the prompts in the at-home engineering kits, which can consequentially influence families' engineering practices. Our work explores how caregivers organize families' engineering learning activities—through the configurations of interactional roles—during the use of at-home engineering kits.

We adopted Engineering is Elementary (EiE) model (ask-imagine-plan-create-improve) to guide our understanding of families' engineering practices (Cunningham, 2009). For younger learners (K-5), the engineering practices of asking is related to understanding the problem scope; imagining and planning relate to the idea generation; creating is concerned with the application of scientific and engineering knowledge to address the design problems; and improving is making optimization on their design (National Research Council, 2012).

Methodology

Our study is a qualitative case study of families with children (6-12 years) who used the at-home engineering kits. The unit of analysis was family members' engagement while utilizing one kit. If one family split up into two groups and used two kits separately, we considered them as two cases. The research team worked with Boys and Girls Clubs and public libraries that had existing relationships with economically disadvantaged families to recruit study participants. Eight families represented European American, Asian, and African American backgrounds. Out of 16 families (27 children) that completed one to five kits and recorded their interaction (230 hours of data), we focused on eight family cases that completed the same kit. The kit included an instruction card and craft materials to construct a package for delivery, out of pasta, that can travel along a zipline to deliver a package to a friend 30 feet away. Four discussion prompts contained questions: 1) prompt 1: What is the function of each container? What kinds of shapes form a good container? What material will you use? Explain your choice of material; 2) prompt 2: Is your container sturdy enough? How do you know? How might the type of pasta make a difference? Is the size and depth of the container appropriate?; 3) Prompt 3: Why do you need a handle and a hook?; 4) prompt 4: Construct a zipline and test your design. Explain how you attached the zipline. Why is your design working or not working? How can you improve your design?

We conducted interaction analysis (Jordan & Henderson, 1995) in two phases. First, we created content logs to identify episodes where families utilized the prompts. When the families' video-records did not provide clear evidence of revoicing the prompts, we did not engage in further data analysis to prevent from making ungrounded assumptions. As such, two family cases were excluded. For each case, we created a narrative account with a summary of how many prompts were implemented and transcribed families' talk that resulted from the implementation of the prompts with screenshots and timestamps from the video-records to provide a "thick description." We further examined the narrative accounts by conducting a thematic analysis to explore the different roles that caregivers took during the implementation of the prompts. Three themes emerged: caregivers as *monitor*; caregivers as *mentor*; caregivers as *partner*. In the second phase, to investigate how three different caregivers' roles influenced families' engineering talks, we coded families' talks at the level of individual's utterances, defined as a turn of speech by a speaker, with atlas.ti. using the coding scheme by Cardella et al. (2013) with three elements: 1) engineering practices (problem scoping, planning, modeling, evaluation/testing), 2) caregiver-child talk types (asking, affirmation, disagreement, explanation), and 3) interest (excitement, frustration). The codes for the engineering practices aligned with the EiE practices. We refined the codebook until there was a consensus on the codes. Consequently, sub-codes were added (e.g., kit revoicing, asking questions to express uncertainty). Coding results were compared and contrasted within and across three different groups. We acknowledge that the study sample in each participant structure is not sufficient to provide generalizability.

Findings

The occurrences of talk demonstrated that families' conversations sparked by the discussion prompts were predominantly related to the engineering practices of planning, followed by equal occurrences of problem scoping and modeling and evaluation/testing (Figure 1). Explanation, asking questions, and providing affirmation/ encouragement were the most frequent talk types. When occurrences of talk were compared across three groups, caregivers as *monitor* utilized all four prompts and the other families used 1 to 3 prompts. The families' talk related to engineering practices and caregiver-child talk types had nuanced differences across three groups. Notably, families with caregivers as *monitor* engaged in more planning talk while families with caregivers as *partner* engaged in more problem scoping talk. Talks related to asking questions to express uncertainty or having conflicts were only evident in families with caregivers who took on the role of *monitor*.

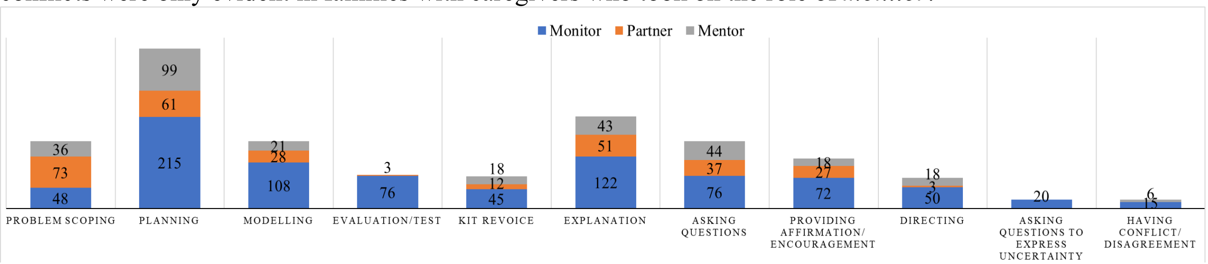

Figure 1. The graph represents occurrences of talk at the level of individual's utterances related to engineering practices and talk types in three groups (caregivers as monitor, caregivers as partner, caregivers as mentor).

Caregivers monitor the design process with faithful implementation of the prompts

Caregivers took on the role of *monitor* by faithfully revoicing all four prompts, which supported families' engagement in all four engineering practices. Edward and Roberto's families that had caregivers taking the role of *monitor* were the two cases that revoiced prompt 2 to test the sturdiness and the appropriate size of the containers. As such, these two families were able to also engage in engineering practice of evaluation and testing, which most families did not engage in (Figure 1). Families' engagement was characterized by product-driven approach—towards constructing a complete prototype that addresses the function—as highlighted in higher occurrences of planning and evaluation/testing talk.

Analysis of families' interaction showed that caregivers used the prompts to provide executive directions on what to do next or provide approval to the child's responses, as demonstrated in the excerpt from Edward's family below. Edward's family discussed what the function of the container would be after revoicing prompt 1. Initially, Edward suggested that the container be easy to use and deliver the package fast. The caregiver disagreed and emphasized to focus on keeping the package secure inside the container. Afterwards, the family did not engage in further discussion to reach a consensus on the function or discuss different ways to add safety features to the container. The episode starts as the caregiver observes Edward making the container.

01	Caregiver:	((shakes head)) You are gonna hurt it, you are gonna hurt it. No, mm-mm (negative)…
02	Edward:	((moments passed; the plastic figure is put inside the container))

03 Caregiver: Ok. I don't think it's the best way, but it's what you wanna do…I am thinking if I had to put you
04 in one of these and sent you across the way, would you want to be in here?
05 Edward: ((frowns)) No!
06 Caregiver: Think about it. Ok. We need to make something that's safer.

The caregiver expressed uncertainty and disapproval towards Edward's design approach (line 1). She expressed disagreement even after Edward successfully put the figure in the container (line 3) since the container did not look safe and secure (lines 4, 6) to address the function that she had emphasized previously. Findings showed that caregivers who took on the role of *monitor* faithfully implemented the prompts to monitor the design process, but also questioned the appropriateness of the child's approach and shifted their design trajectory towards implementing approaches that caregivers perceived as important.

Caregivers mentor to mitigate challenges through on-the-fly use of the prompts

An additional role that caregivers took on was that of *mentor*. In Sara and Eden's families, caregivers mentored their children by utilizing the prompts on-the-fly to mitigate challenges experienced by the children. Sara and Eden were part of the same family, but each worked with different caregivers. (Therefore, two separate video-records were created.) Sara, being the older sibling, independently worked on the engineering challenge without much challenges by using the instruction card. Eden, on the other hand, experienced difficulties understanding the engineering challenge and the constraints, although the caregiver had previously utilized the discussion prompt 1 to discuss them. After discussing prompt 1, the caregiver left to do chores. When the caregiver started observing Eden after she finished her work, Eden stated: "I have no idea what I am doing." The caregiver then helped Eden to construct the container. The episode starts after the caregiver reads the discussion prompt 4 to brainstorm ways to attach the container to the zipline.

01 Caregiver: How will we ((looks at the prompt)) attach this zipline? ((rephrases the same question again))
02 Eden: You just use another pipe cleaner ((attaches to the container)) but then it would…
03 Caregiver: What other materials do we have in here?
04 ((Eden mentions fishing line, scissors, paper clips, rubber bands.))
05 So, let's think about what might….let's… you wanna feel this ((passes the fishing line))?
06 Eden: ((feels the fishing line))
07 Caregiver: What might slide along there very easily?
08 Eden: ((takes paper clip))

The caregiver utilized the discussion prompt and asked questions to help Eden notice a material that might slide easily along the zipline (lines 1–2). As Eden was unable to notice the material property of the paper clip, the caregiver asked Eden to feel the fishing line (line 5) and find a material that might slide down the fishing line (line 7). As highlighted in the episode, the caregiver positioned herself as the mentor who would step in to mitigate challenges experienced by the child—by utilizing questioning to strategically guide the child find ways to address the engineering challenge. While the caregiver continued to encourage the child to brainstorm and design the prototype, it was often challenging for Eden to figure out ways to construct the container or address challenges on his own. As such, the caregiver had to step in to provide strategic questioning and explanations to co-construct the container and the zipline. Later, Eden and the caregiver successfully constructed a zipline that delivered a package by adopting a pulley system. However, Eden expressed a lack of ownership over the design as the caregiver initiated many ideas: "I think I am copying Sara (his sister)." Without opportunities for the child to make sense of and resolve his inquiry steps, as the caregiver stepped in to deliver suggestions, the feeling of accomplishment at the end of the engineering challenge was low for Eden.

Caregivers partner with the children through equal usage of the prompts

The last role that caregivers took was that of *partner*. In two family cases (Billy, Abby), caregivers and children worked as partners by posing questions and suggestions while equally utilizing the prompts. A notable difference in this group was high occurrences of problem scoping talk (Figure 1). Billy's family discussed how long 30 feet is; Abby's family discussed which toy to send to estimate the size of the container. We note that similar type of problem scoping was not evident in other cases. Another notable difference was the level of caregivers' participation. The caregivers engaged as partners alongside the children who also questioned, shared uncertainty, and proposed ideas throughout the engineering design process instead of only voicing opinions when challenges emerged as an outsider. We present an episode to illustrate how caregivers took on the role of *partner*. Prior to the episode, Billy read aloud prompt 1 and began to sketch out his plan for the container. The caregiver revisited the prompt and questioned how the container could travel back and forth to deliver a package.

01 Caregiver: In the olden days…you could pull the clothing line towards you and then it would go back out.
02 Billy: Yes, but that's…we can do that, Mom. ((notices)) There's fishing, fishing line!
03 Caregiver: Do we want to use gravity or do we want use more like pull?

04 Billy: Pull.
05 Caregiver: Because why?
06 Billy: Because gravity would be hard.
07 Caregiver: If it was gravity, it would only be able to go to, let's say to Lia's house. But we couldn't get it back…

The caregiver continued to inquire different possibilities for creating the delivery system by suggesting a pulley (lines 2) and gravity (line 3) to deliver the package. When Billy quickly dismissed the possibility of using gravity (line 10), the caregiver continued to question whether gravity would be an appropriate option given that creating a different height between departure and arrival points, thus using gravity, would only work in one direction (line 7). After this episode, Billy resisted to inquire about this topic further as he emphasized sketching out their plans first to complete the challenge. As illustrated in the episode, the caregivers who took on the role of *partner* engaged in the engineering activity with genuine interest to construct a working solution by posing questions and suggestions. However, in two family cases, an opportunity for further inquiry was often constrained by the child's intellectual values on the completion of tasks.

Discussion and conclusion

Our preliminary findings from six family cases illustrate forms of guided participation (Rogoff, 2003) that caregivers took on to organize families' engineering learning activities at home. Barron et al. (2009) have shown that caregivers support children's technology engagement by taking different roles as their learning partners. Our case study findings demonstrate that caregivers took on roles as *monitor, mentor, and partner* which both enabled and constrained different types of engineering practices and caregiver-child talk types. While faithful implementation of the prompts by caregivers who took on the role of *monitor* was supportive towards engagement in engineering practices, the asymmetric relationship in which the caregiver was positioned as the knowledge validator seemed to echo the rhetoric of hierarchy. Caregivers who took on the role of *mentor*, as highlighted in Eden's case, demonstrated that moments of learning opportunities that emerge from the child's inquiries may not be taken up *just-in-time*. The on-the-fly support from the caregiver in Eden's case enabled the family to co-construct a working prototype; however, questions remain as to whether the caregiver's support also enabled Eden to take ownership of their prototype. Caregivers that took on the roles of *partner* demonstrated that caregivers' active participation to learn and motivation to guide their children in inquiry process can be hindered when children's motivation and goals are not aligned with that of the caregivers. One possible solution that can be embedded in the discussion prompts is to communicate the importance of taking up one another's ideas, questions, warrants—however small they may be. It may be necessary to first support family members to understand that the informal engineering learning activity as an opportunity to construct and evaluate knowledge rather than simply completing the challenge. In future, we hope to investigate further how different design elements in the at-home engineering kits, including the prompts, can provide learners to embody engineering ways of thinking without the presence of a facilitator, while considering the role of family members.

Embodied Design versus Dynamic Visualization: Benefits for a Far Transfer Problem Solving in Trigonometry

Anna Shvarts, Utrecht University, the Netherlands, a.y.shvarts@uu.nl
Gitte van Helden, Delft University of Technology, the Netherlands, g.vanhelden@tudelft.nl

Abstract: The development of digital technologies enables visualizations of many scientific relations. In this paper, we question the efficiency of the visualizing tools from a theoretical perspective that combines cultural-historical and radical embodied approaches. Dynamic visualizations expose the target relations in a ready-made form, while embodied action-based design provides students with an opportunity to re-invent the target relations through active sensory-motor coordinations. In a multiple-case study, we compare these design genres for learning trigonometric relations. While dynamic visualizations were more efficient in simple tasks, embodied action-based design enhanced students' reasoning in a far transfer task.

Introduction

New technological tools provide unique opportunities for visualizing scientific relations, such as relativity theory principles in virtual reality or trigonometry relations in dynamic geometrical environments (e.g., DeJarnette, 2018). Putting the development of digital technologies in the broader context of technology evolution in society, researchers from cultural-historical tradition stress that technologies appear as a reification of cultural practices (Pea & Cole, 2019; Wenger, 1998). The most stable aspects of practice become fixated in a form of visual inscriptions and other artifacts. When providing students with a visualization of some mathematical or scientific relation, educators present a former scientific practice of establishing the target relation in a ready-made form. For example, a sine function was constituted in the history of mathematics as a practice of relating an arc on a circle to a chord (Toomer, 1974); a sine graph appeared later as depicting this relation (presumably by Albert Dürer). In many textbooks a sine graph is drawn as already connected with a unit circle. In this case, students come to learn about this relation in a ready-made form.

However, some approaches postpone involving ready-made scientific artifacts into teaching practice (e.g., Gravemeijer, 1999). The students are invited to re-invent the target mathematical or scientific relations—such as a relation between an arc and *y*-coordinate on a unit circle to *x*- and *y*-coordinates of a sign graph—in their own practice before embedding them into artifacts and technologies. These approaches are particularly meaningful from a radical embodied perspective that considers cognitive functions to be complex dynamic systems of perception-action loops (Abrahamson & Sánchez-García, 2016; Chemero, 2009). As students learn to use cultural artifacts, they incorporate artifacts into their extended cognitive functions by including them into perception-action loops. We suggest referring to this process as a genesis of *body-artifacts functional systems* (Shvarts, Alberto, Bakker, Doorman, & Drijvers, under review). In this study, we investigate if educational technology that invites students to re-invent a sine graph is beneficial for furthering students' reasoning compared to the technology that automatically generates a sine graph without students' active participation. We expect that the students who re-invent artifacts that reified mathematical practices—such as a sine graph—acquire perception-action loops for building these artifacts. Later, they might use the understanding of artifacts' constitution in reasoning. Contrary, students who encounter an artifact as automatically generated, might lack understanding of how it was built, similar to using a smartphone without knowing how it works.

Action-based embodied design versus dynamic visualizations

Various dynamic visualizations have been designed to show the students the relations between a point on the unit circle and a correspondent point on a sine graph (e.g., DeJarnette, 2018). In these technological solutions, educators invite students to *observe* mathematical relations, which are already embedded into technology. However, the demonstration of the relations does not automatically lead to their understanding by the students (Yerushalmy, 1991), questioning these designs' efficiency. As we combine a cultural-historical approach that states that perception develops (Radford, 2010; Vygotsky, 1997) and a radical embodied approach that claims perception serves action (Abrahamson & Sánchez-García, 2016; Maturana & Varela, 1987), we might wonder if the students are able to *notice the target relations* that designers are trying to show them.

Action-based embodied design (Abrahamson & Sánchez-García, 2016) provides a principal alternative to visualizing technologies. Mathematical relations are not explicitly exposed to the student, but delivered as a motor problem (Bernstein, 1967). Embodied interactive activities provide continuous feedback to students' hand-movements. Aiming to receive positive feedback, students maintain target distances on a visual display in a target mathematical relation. Thus students reinvent mathematical relations and artifacts in their sensory-motor practices. Instead of relying on students' existing perception abilities, an action-based embodied design fosters the development of new forms of perception by establishing sensory-motor coordinations.

The essence of the difference between dynamic visualizations and action-based embodied designs lies in the different answers to the question, "Who gets to constrain the student's interaction with the virtual objects: the software or the student?" (Abrahamson & Abdu, 2020, Context section). The embodied action-based design's research program assumes that emergent task constraints in interaction with a student might be beneficial for targeted conceptual learning. In this study, we collect empirical evidence to corroborate or reject this theoretical expectation. Thus we question: *What are the differences in reasoning about a novel trigonometry problem in learning with action-based embodied design and learning with interactive dynamic visualization?*

Methodology

We report the results of a contrasting multiple-case study (Miles & Huberman, 1994) that compares two design genres: embodied action-based design and interactive dynamic visualization.

Learning materials

Both types of interactive designs were programmed in the Numworx digital environment within broader design research on the embodied approach to trigonometry learning (see Alberto, Bakker, Walker-van Aalst, Boon, & Drijvers, 2019). There were four parts in the learning materials dedicated to (1) sine value in a unit circle; (2) relation between an arc of a unit circle and x-coordinate of a sine graph; (3) relation between a sine value in a unit circle and y-coordinate on a sine graph; (4) constructing a sine graph by relating an arc and a sine value on the unit circle to x- and y-coordinates of the sine graph (see Figure 1). Each part consisted of three sequential types of tasks: interactive sensory-motor task, reflection task, and mathematical task. In sensory-motor tasks, the students studied the relations between a point on a unit circle and a point on a sine graph. Then the students reflected on these relations in written form and through multiple-choice task. Finally, they solved mathematical tasks based on the studied relations.

Contrasting conditions

In the action-based embodied design condition (ED), the students studied the target relations in the form of a motor problem as they manipulated two points: a point on the unit circle and a point on the Cartesian coordinates. Continuous feedback from the system informed them when the points were in the corresponding positions by changing the color from red to green (see Figure 1). As students continuously maintained green feedback, they developed new coordinations, thus incorporated the target mathematical relations in their bodily functional system of perception-action loops. In the dynamic visualization condition (DV), the students moved only one point on the unit circle, while the point on the Cartesian coordinates was automatically moved in correspondence with the first point. So the experimental factor determined whether the students were maintaining the target relation in sensory-motor enactment based on the feedback or whether the target relation was maintained by the software and exposed to the students in a ready-made form. Figure 1 shows tasks from two conditions in Part 4. The reflection and mathematical tasks were the same in both conditions.

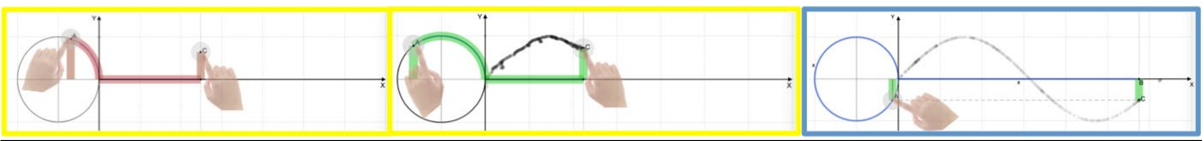

Figure 1. Embodied design (in a yellow frame, red and green feedback, ED): a sine graph emerged from active coordination of two hands. Dynamic visualization (in a blue frame, DV): a sine graph was automatically generated when moving one hand around the unit circle.

Research protocol and participants

The procedure consisted of a pre-test, learning stage, a post-test, and an interview. The post-test included near transfer tasks similar to the tasks from the learning materials, such as estimating $\sin(\frac{7}{12}\pi)$ and drawing a graph y=sin(x), and far transfer tasks such as estimating sin(12) and drawing a graph of y=sin(2x). In the interview, we asked the students to explain how they solved the post-test tasks and scaffolded them towards accomplishing these tasks in a case of mistake, thus investigating their reasoning. All data collection was run online. The students (14-15 years old) had no pre-knowledge in trigonometry beyond trigonometric relations in a right triangle. Three students learned with embodied design and four students learned with dynamic visualizations.

Results

In solving the algebraic near transfer tasks in the post-test, the students from the DV condition performed better than the students from the ED condition: four DV students answered 100%, 57%, 50%, and 29% of the tasks, while there ED students answered 50%, 29%, and 14% of the tasks. In two cases, the ED students were still unsure how to quantify the sine value on a unit circle. However, as soon as the researcher in the interview would ask the students to recall their embodied experience, they could easily correct their mistakes. The disadvantage of ED might be explained by the need to communicate with a real tutor for a successful transition of embodied experiences into mathematical discourse when learning with embodied designs (e.g., Flood, 2018). This communication was provided only in the interviews, after the post-test.

For the drawing tasks, students from ED condition clearly benefited over students from VD condition. The vivid differences were observed in the far transfer task of drawing the graph y=sin(2x). The most challenging part of this task lies in the idea that the graph's period is two times smaller when x is multiplied by two. As Table 1 illustrates, all three students from the ED condition expressed this change in the period in their drawings. They could explain their drawings referring to the point moving around the unit circle two times quicker for the formula y= sin(2x), and, consequently, the waves of the graph appearing more frequently. Only one out of four students from the DV condition came up with this change in the graph; two students drew the graph extending in the horizontal direction, and one did not come up with any drawing (not shown in Table 1).

Table 1: Students' drawing of in the post test: initial sine graph and sin(2x) in the far transfer task.

Embodied action-based condition (ED)			Dynamic visualization condition (DV)		
	y=sin(x)	y=sin(2x)		y=sin(x)	y=sin(2x)
Ellie			Mark		Janice			Bella		Emma			Yana		
Emma, a student from the ED condition, explained: "*I assume that with 2x that [point] on the circle will travel twice the distance, instead of [the same distance as] on the x-axis.*" While explaining, she doubled two distances in her gesturing around the unit circle: she stopped at the distance π/6 and then at the distance π/3, she then stopped at the distance π/2 and then at the distance π. Further, Emma moved synchronously two fingers in the air, one going around the circle and another going on the x-axis, thus repeating the enactment from the embodied learning. However, in this gesture, she moved the finger around the unit circle faster, in correspondence with the new formula. Emma dived into the process of constructing the sine graph from a unit circle as she gestured out the coordination of the distance along the unit circle and the distance on the graph bodily adjusting this sensory-motor coordination to the new situation. The other ED students gave similar explanations, referring to their experiences of coordinating a point on the Cartesian plane with the unit circle.

The students from the DV condition also recognized the unit circle as being useful for building a sine graph. However, they could not adjust the construction process to the new situation. Instead, they were trying out any option of enlarging or diminishing the sine graph two times in a vertical or horizontal direction. Mark referred to the unit circle explaining how the initial sine graph was built, but then concluded with enlarging the graph along the x-axis doubling the distance due to the multiplication: "*Now it says 2x so I think that now the arc of the graph that is above the x-axis is twice as long. Because the distance that is covered on the circle is twice covered in the graph.*" Ada had drawn nothing, and when asked in the interview she supposed the graph should be two times longer. Later she changed her mind and suggested that graph "*Will become double as high.*" Yana had a correct idea of diminishing the graph's period: "*I thought I am just going through that circle twice. […] That I was just going to draw it [a wave] twice.*" However, she was uncertain and changed her mind: She gestured along y-axis and said that she should adjust the graph along y-axis as sine is y-value.

The students from the DV condition reasoned about the sine graph as an outcome of the construction procedure (which was done by the machine during their learning). They tried out any possible transformation that would match a change from x to 2x and did not consider if these suggested transformations harm the relations between a sine graph and a unit circle. On the contrary, ED students had embodied experience of actively re-inventing a sine graph based on a unit circle. This experience helped maintain the entire operation of graph building coherent and implement the formula's changes into this operation.

Conclusions

The embodied experience of actively coordinating distances on a unit circle and Cartesian plane helped the students from the embodied design condition (ED) realize how the sine graph was constructed. The students could apply this understanding in further reasoning about a composite function graph without being ever taught this new material. Thus, an embodied design might facilitate creative problem-solving in far-transfer tasks. Remarkably, students' reasoning involved adapting the sensory-motor coordinations, thus it run at the embodied level. For the students from the dynamic visualizations condition (DV), a sine graph was not constrained by their own enactment but by the software (Abrahamson & Abdu, 2020). The students could not flexibly adjust the procedure of sine graph construction to the new situation. Instead, they tried to adjust an outcome of constructing procedure—the sine graph per se. Without caring about relations between a unit circle and a sine graph, the students tried to enlarge y=sin(x) graph in *some* direction, matching the multiplication in the formula.

Ready-made mathematical relations—exposed in dynamic visualization of a sine graph—presented mathematical practice in a reified form (Wenger, 1998), thus an artifact—a sine graph—extended bodily functional system (Shvarts et al., under review) in a rigid way and fostered unwarranted manipulations. The embodied action-based design provided an opportunity to actively constrain the target relations. The students appropriated trigonometric relations into perception-action loops of their flexible body-artifacts functional systems. Once the mathematical relations were included in the systems of perception-action loops, the students could adjust them to a novel situation in further reasoning. While this small-scale study results are well explained from the chosen theoretical perspective, further scaling up is needed to corroborate the conclusion of the embodied design effectiveness over dynamic visualizations in far-transfer tasks.

Abstract: From the first iteration of a design-based research study with 16 families, we investigated at-home intergenerational exploration of pollinators and plants. The team developed a mobile augmented reality app focused on plant-pollinator interactions. We investigated how AR elements influence families' learning in their backyards. This analysis informs the design of mobile augmented reality apps that are site-independent for families' collaborative learning opportunities in outdoor, home-based settings.

Keywords: Informal learning, science learning, mobile technologies, augmented reality, family learning

Mobile augmented reality apps supporting learning at home

Sharples and Pea (2014) theorized a sociocultural view of mobile learning as "context-sensitive learning," where learning is embedded within interacting contexts of social, material, environmental, and individual resources. Mobile devices, with their range of affordances, enable designers to reimagine configurations for how and where learning takes place (e.g., Kawas, et al., 2019). Mobile augmented reality (MAR) expands opportunities for learning within real-world places through a virtual layering of digital material that can be viewed on devices in outdoor spaces (Ryokai & Agogino, 2013). MAR uses digital resources to reveal disciplinary meanings of a place that may not be visible to learners directly (Dunleavy & Dede, 2014). Our place-based MAR concept focuses on designing "micro sites" (Sharples & Pea, 2014) for families' science learning that draws upon both planned and emergent experiences within a setting to create out-of-school learning opportunities.

We conceptualize MAR as a cultural tool mediating science learning while people move through their community. MAR has been designed to augment science learning in the natural world in places such as parks, gardens, ponds, and woodland settings (e.g., Georgiou & Kyza, 2017). We add to the MAR designs the concept of learning-on-the-move, (Silvis et al., 2018; Taylor, 2017) where movement through familiar spaces supports people as they make sense of new information. Silvis et al. (2018) investigated families' technology practices within an ethnographic study and found that mobile computers and other technologies were integrated as learning tools in homes and communities. Similarly, Taylor (2017) used ethnographic methods to explore how youths came to understand their community as a designed, complex system.

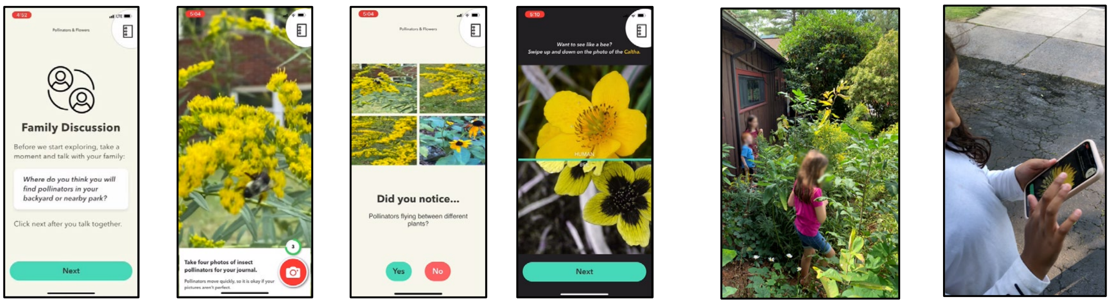
Learning scientists argue that to engage in scientific observations, people must be facilitated to notice scientifically through joint attention and guided participation (Eberbach & Crowley, 2017). Eberbach and Crowley found that parent-child conversation during their shared focus on insects and plants was an essential mechanism for understanding pollination. Using *wh-* questions is one of Eberbach and Crowley's elaborative conversational strategies to direct attention and elicit meaning-making conversations. Marin (2020) investigated observing-on-the-move in families with children as they walked together in forests; she explained how people's talk and movement across landforms work together to shape the families' field for observing and story-telling. We build from these findings to explore how MAR can engage and support families as they move and talk together to notice scientific phenomena in their backyards. As such, we ask the following research question: *How does a mobile augmented reality app support families to notice key features of pollinators and plants in their backyard?*

Methodology: Iteration one of a design-based research project

Using a sociocultural theoretical framework, we adopt cultural psychology-informed DBR (Bell, 2004), relying primarily on qualitative analyses of talk and action to understand how the MAR app could serve as a cultural tool. Our work here is the first iteration of an app on pollinator-plant interactions.

The *Backyard Explorers* MAR app features and technology

The *Backyard Explorers* experience was approximately 15-20 minutes. The app was divided into three sections: (a) Pollinators and flowers; (b) Seeing what we can't; and (c) Be a pollinator friend. Families were prompted to discuss where they think they will find pollinators in their yard (Figure 1a). Then, they were encouraged to locate flowers in their yard to observe pollinators. Families were offered a list of behaviors to attend to and were prompted to take four photos of pollinators (Figure 1b). Once complete, the photos are displayed on the screen as they answer five yes/no "Did you notice…" questions, which serve as a checklist (Figure 1c). This sequence of noticing key scientific features, photo-taking, and yes/no questions was repeated for flowers. After, the families were prompted to observe one pollinator closely and take a 10-second video. The next section of the app, *Seeing what we can't*, used AR to illustrate scientific phenomena that are difficult to see in one's backyard. One activity called 'See like a bee' illustrated through AR filters how some pollinators can see the colors from the light spectrum in ways that humans cannot (Figure 1d). The last section, *Be a pollinator friend*, prompted families to select from a list of activities they could engage in stewardship actions to promote pollinator wellbeing. All families completed the pollinator and flower activities; however, only five families completed the last activities.



(a) (b) (c) (d) (e) (f)

Figure 1: Images a) – d): our screenshots from the *Backyard Explorers* app: a) family discussion activity (left), b) photo-taking activity (middle left), c) one screenshot of the yes/no questions that make up the pollinator observation checklist (middle right), and d) the bee vision slider. Images e) and f) are families using the app.

Data collection and analysis

Data were collected via an online social distancing protocol due to the COVID-19 pandemic. Sixteen families living in rural counties completed the MAR app experience (18 adults, 28 youths). Participants reported themselves mostly as White (White: 85%, Hispanic or Latinx: 6.5%, No answer: 8.7%, Other: 2.2%). Children (female: 46%, male 54%, non-binary: 0%) were primarily between the ages of 5-12 (89%). Seven guardians were educators (39%) (e.g., teachers, professors); four were homemakers (22%); and other occupations were farmer, camp director, and self-employed. Six families (37.5%) homeschooled their children. Due to COVID-19, all families had to have internet access and an iPad or iPhone to participate (normally, families can borrow equipment). Lack of broadband access and high unemployment during COVID-19 stay-at-home orders limited our research; unfortunately, we only reached rural families with their own technological resources during this study period.

Primary data sources are *Backyard Explorers* screen recordings, which captured 15 families' voices, app interactions, and video from the AR browser of the families' yards. Five recordings were not fully captured. Additional data include (a) photographs and videos from four families, (b) online demographic surveys through Qualtrics, which included zip code, race/ethnicity, occupation, and age, and (c) pre- and post-experience interviews via the Zoom platform. In the post-interview, families were asked about their overall experience.

We conducted a qualitative analysis of the screen recordings via interaction analysis (IA) (Jordan & Henderson, 1995). The videos were professionally transcribed and confirmed for accuracy by two researchers. The authors held four co-viewing IA sessions to watch the 15 recordings. The team took notes on how the families: (a) talked about pollinator and plants, (b) used AR, photography, and checklist questions, and (c) made connections to their local community, home, and neighbors. Next, the IA notes were developed into codes to understand the families' experiences with our MAR app. Three authors coded the videos to compare and contrast the families' experiences, and then the code segments were placed in a shared spreadsheet. Based on the IA session notes and coding spreadsheet, themes were selected for this paper on how the MAR app worked as a cultural tool to support people to notice key scientific elements in their backyards. The first author selected two families' talk and actions to include in this analysis because these families clearly illustrated the phenomena of interest: noticing plants and pollinators in their backyard while engaging with the MAR elements of the app. Discussions were used to ensure confirming and disconfirming episodes were considered in the development of final analyses.

Findings

From the 15 families' screen recordings, we found that the pollinator MAR app supported talk that indicated they were noticing key concepts related to pollinators — including the presence of insects, insects on flowers, the color of flowers, and the types of plants in their yards. All families self-reported during the post-experience interview that the MAR app supported the way they saw pollinators and plants in their backyards.

Noticing key scientific phenomenon with the MAR app photo-taking and checklist

All families used the app and its checklist and prompts (in the form of yes/no questions) to notice scientific aspects of plants and pollinators. For example, a father and three children (Ava and Jillie, two 7-year-old girls, and Liam, a 3-year-old boy) used the app to observe pollinators on milkweeds, goldenrods, and daisies. The father used the app to ask questions to guide the children to notice aspects of the pollinator's behaviors:

Dad: So, what do you see? What are the bugs doing? Or what are the insects doing that we see?

Ava: They're landing on the flowers and then flying to other flowers. ***[noticing]***

Dad: Yeah, they really are. They're going from flower to flower. ***[noticing]***

Jillie: Oh daddy! I see a bee. ***[identification]***

Ava: A bumble bee. ***[identification]***

Dad: Yeah. I don't even know if that's a bumblebee. I think that might just be it. Oh, Oh, that big one. Oh yeah. That is a bumblebee. ***[identification]***

Liam: Where?

Dad: I think there's one on the, on this, on the golden rod over here. ***[identification]*** Liam, look straight ahead. ((crosstalk)) Yeah. It's just crawling all over the flower. ***[noticing]***

The excerpt shows the father started prompting the children to talk about the pollinator they saw, as suggested by the app. A conversation between Ava, Jillie, Liam and their father ensues where the family alternates between noticing key pollinator behaviors from the app and identifying plants and insects.

The family next walked to the plants alongside the wooden fences on the path in front of their house to find more pollinators such as bumblebees, honey bees, yellow jackets, and monarch caterpillars on plants. After taking photographs, the father read aloud the pollinators' observation checklist in the app (Figure 1c) to recall their children's observation about the pollinators and facilitate their ability to notice essential details.

Dad: Okay. Did you, have you seen pollinators sitting on one type of plant? ***[reads checklist]***

Ava & Jillie: //Yeah.

Dad: Yeah. Like that bumblebee. Just really did not want to leave. ***[recalls previous noticing]***

Jillie: It was just curling up ***[recalls the previous noticing]***

In this family case, similar to others in our dataset, the father used questions and content in the app, such as the checklist, to support the children's observation of pollinators. As the children observed the pollinators on the move in the garden, they attended to the physical environment and phenomena and engaged in the app's activities and content at the same time.

Using AR to connect backyard plants to the scientific phenomenon

In addition to using the app to support noticing insects and plants, five of the fifteen families used the MAR elements to make visible scientific phenomena in their backyards that they could not see without additional digital augments. An example of this comes from one family (Mother and Sofía, 7-year-old daughter) using the Bee Vision MAR (Figure 1d) to help further understand how bees could find the pollen and nectar in flowers.

Mom: Look. What do you see? Want to see like a bee? Swipe up and down from the photo. Okay, look, this is how a human sees it. And that's, that's how a human sees it and that's how a bee sees it.

Sofía: They see as black and brown? I mean, black and yellow?

Mom: Here, you can swipe it up and down to see. That's the human. And then, when you go up, that's how the bee sees it.

Sofía: Whoa... How, how does this help, how does this help them see the nectar.

Mom: Maybe they can like [inaudible] if they're more attracted to that color.

Sofía: Maybe they are.

Sofía engaged with the bee vision interface, swiping the AR representation back and forth (Figure 1f) while commenting on how people see the flowers versus how bees see them. Sofía said, referring to a flower in her backyard based on what she learned in the app about how insects see different aspects of light spectrum: "*This is a dry, dry land with just black and purple flowers. Mmm, that's pretty. That's the one we saw in the backyard. And there's a bunch of little ants in there.* [inaudible] *That's how they see it [the black and purple flowers]? That's terrible.*" Sofía did not appreciate how the flowers looked through the ultraviolet light simulated visualization (i.e., terrible). While she and her mother did not use scientific language like wavelength, they noted that insects could see flowers differently than humans and that helped pollinators found flowers. This case shows the utility of visualization of the bee vision to teach families about science in their backyard gardens.

Discussion

Our work informs the learning-on-the-move (LOM) theory by building on prior findings about LOM with technology (Silvis et al., 2018; Taylor, 2017) and without (Marin, 2020). Similar to Taylor's (2017) findings that mobile technologies can guide youth to create meaning in their own neighborhoods, our study shows promise for the potential of site-independent, mobile AR to support science learning in people's backyards. In regard to advancing the design of MAR technology for use in communities, our findings suggest that the *Backyard Explorers* app supported noticing, and the MAR features helped families to understand ideas that they could not easily see otherwise. To design such immersive experiences, researchers must consider the interactional, cultural context that people bring and create as they use mobile computers in situ (Georgiou & Kyza, 2017).

Regarding design implications from our findings, the summary of the fifteen screen recordings demonstrates that the yes/no checklists and discussion prompts supported families' observing-on-the-move in each of their different backyards. Ava, Jillie, Liam, and their father exemplified how these two elements were integrating into noticing, identification, and recall. From the five families that used all of the MAR elements, these were supportive of family talk around science that was not visible in the garden without enhanced visualization. The case of Sofía and her mother illustrates one example of how a family was able to look at the bee vision visualization and apply it to the flowers in their own garden. Future design and analyses will look more closely at how families use familiar referents, objects, and stories (Marin, 2020) to talk about pollinators' behaviors, plant diversity, and other flora and fauna in their backyard.

Impact and Resilience: A Survey of Youth-serving Organizations During the Pandemic

Caitlin K. Martin, CKMartin Consulting, ckmartin.consulting@gmail.com
Sheena Erete, DePaul University, serete@depaul.edu

Abstract: The pandemic has shifted everyday realities of how we work and learn. Massive layoffs and shelter in place orders have led to unemployment and shuttering of local businesses across the country. There is widespread concern about youth and teen social and emotional health and loss of opportunities for meaningful engagement. While we know that youth-serving organizations are essential for youth learning and development, less is known about how those organizations are faring during this time. In this study, we present findings from a citywide survey of Chicago youth-serving organizations (N = 126) indicating that although there are challenges and needs resulting from the pandemic, there is also an important story of resilience and adaptation as the majority creatively shift their practices and engagement to the virtual space to continue to support youth and families in the communities they serve.

Keywords: COVID-19, out-of-school providers, equity, youth participation, resilience

Introduction

Concerns about academic achievement and social and emotional health for youth and teens are widespread. Researchers predict lower standardized test scores relative to a typical school year due to remote schooling (Kuhfield et al., 2020). Youth and teens are experiencing anxiety and fear, and the closing of locations where they spend time and connect with others means less structure and supports essential for mental well-being (World Health Organization, 2020; Darling-Hammond et al., 2020). These and other studies (e.g., Dorn et al., 2020) suggest that negative effects of the pandemic may be greatest for low income, Black, and Hispanic young people.

Youth-serving organizations and program providers (e.g., mentors, library and parks staff) support young people in learning and developmental outcomes including and beyond traditional school measures, such as creativity, confidence, and plans for the future (e.g., Montgomery, 2017; Sebring et al., 2013). While those people and services are essential for youth in this time of crisis, the pandemic has destabilized employment and services across the country. Recent analyses of US Bureau of Labor Statistics data reveal that low wage, part time, young, and minority workers are the most likely to hold jobs in danger of being cut or reduced (Dorn et al., 2020; Center on Budget and Policy Priorities, 2020). People who work with youth in out-of-school settings often fit such a profile and their lack of job security is documented in general (Baldridge, 2020) and during the current global health pandemic (Moore, 2020). Places where youth workers are employed are also impacted. A survey of nonprofits reported loss of revenue, reduction in services, and employment cuts (The Independent Sector, 2020). Despite this bleak picture, we also know that communities that have historically experienced some of the most social challenges also demonstrate immense resilience defined as "patterns of positive adaptation in the context of past or present adversity" (Riley, 2005).

Though it is apparent that structural challenges are even more visible during a pandemic, little is known about what youth-serving providers and organizations in particular are experiencing during this time and how they are adapting services. In this study, we present findings from a citywide survey of Chicago youth-serving organizations (N = 126) to explore the questions of: (1) How did organizations shifted their practices during the first wave of the pandemic (i.e., spring/summer 2020)? (2) What worked and what challenges do they face? and (3) What are their plans for the near-term future while the pandemic remains a reality?

Methods

A 22-question Qualtrics survey was designed to tap into four primary areas, including (1) information about the organization and who they serve, (2) strategies and capacity for communication with and opportunities for youth during the summer of 2020, (3) what worked and what they struggle with, and (4) needs of community and plans for the remainder of the calendar year. Questions included Likert-scale and multiple-choice responses as well as open-ended queries. Researchers are collaborators in *My CHI. My Future*, a Chicago Mayoral initiative conceptualized before the pandemic, focused on building a community of practice with citywide youth-serving organizations with the goal of equity in out-of-school time opportunities. An invitation and link to the survey was sent out in the initiative's weekly email. The survey was open from August 20 through September 25, 2020.

Participants

One hundred and forty-three individuals responded representing 126 unique Chicago youth-serving organizations, including city agencies (e.g., parks and libraries) and community-based organizations focusing on particular areas of learning and practice (e.g., technology, STEAM, arts, boxing) and youth services more generally (e.g., faith-based centers, Boys & Girls Clubs, BSA). Organizations served youth from preschool through 24 years old; most served multiple age groups and over three-quarters served middle (79%) and high school (84%) youth. They represented both smaller and larger organizational spaces (31% served 0-25 youth at one time in their physical space while 24% served over 100). Forty-one percent of organizations served youth across the city while the majority (59%) served one or more particular community areas closely (Chicago is broken into 77 geographically defined community areas). Sixty-seven communities were represented, with the highest representation of service in communities identified as most "socially vulnerable" (Center for Disease Control, 2020).

Findings

Organizational impact: "I don't know where to start; it feels like everything has been impacted"

Impact on organizations due to the pandemic was both positive and negative. At the time of the survey, 10% of organizations reported that they had lost their physical space, 3% were in danger of closing, and many described reduced funding streams in open-ended responses. Nevertheless, the story of impact is more complex than expected. Descriptions reveal details about the adaptive and creative processes organizations engaged in and most focus on short-term but positive predictions about the future, with one respondent saying, "We were at risk of closing but are finding our way forward day by day, [COVID] impacted the way we roll out programming."

Staff who kept their jobs gained knowledge and support. While a quarter of organizations (25%) reported that staff were furloughed or let go, respondents also reported personal and professional benefits for staff employed through the spring and summer. Over half reported staff developing new pedagogical knowledge about how to serve youth remotely (59%), and close to a third saw an increase in mental health/social emotional support for staff (30%) and internal staff bonding and organizational support (27%). Over half (59%) reported new or deeper collaborations with youth service providers and organizations outside of their own.

Despite reduction in programming, organizations continued to serve youth and families. Half of organizations offered fewer youth programs and limited hours of service during the summer (49%), but the vast majority (91%) did manage to continue providing programs, activities, and/or resources to youth and families and 64% did so regularly. Some were able to offer face-to-face opportunities (32%) but the majority adapted their usual approaches. Most moved online: 80% offered live programs virtually, 51% held Internet-based community events, and 50% offered asynchronous online activities for kids and teens to do on their own time.

Breadth of service was diminished but some saw increased depth and formed new relationships. While more than half of organizations (53%) reported serving fewer youth and families than usual, almost a third established new or deeper relations with youth and community they serve (29%) and broadened their reach to serve new youth (27%). Sometimes both happened simultaneously within the same organization. One respondent shared, "Though some of the youth and schools that we serve have not participated in our virtual programming, we have seen new students and new opportunities appear (in other words, we were able to serve fewer youth than normal AND we broadened our reach to serve new youth)."

Successful strategies: "Providing activities that opened [youth participants'] eyes to the world"

Organizations reflected on what worked during their quick pivot to remote learning and reflected on plans for continued services during the 2020-21 academic year, which Chicago Public Schools (CPS) began remotely. One provider advised, "Patience is key, and adjusting expectations for an online environment is a must."

Individual and synchronous methods of communication were preferred. Almost all organizations (96%) remained in touch with the youth and families during the summer of 2020. When asked which strategies were most effective for keeping in contact, almost three quarters (73%) identified video conference tools, half relied on mobile phones (52% through text messaging and 51% through direct calls), and some reported email (42% through listservs and 40% through individual correspondence). Most used multiple strategies, with one person saying, "Not all households are the same and youth may or may not feel comfortable with that and will not respond to any calls. We had to adjust in our approach and how we communicated with the youth in a safe and healthy way which for some were video calls, phone calls, and others it was text messaging." Many emphasized that personal approaches were essential, saying: "Individualized contact is very important. Reaching out and making sure that families know that we are here to support in whatever way we can has made a difference and allows families the opportunity to open and share their thoughts, concerns, and feelings during this challenging time."

A range of participation strategies were utilized, with a preference for authentic opportunities. Most organizations offered remote participation opportunities for youth (87%) in a broad range of content areas, with the highest frequency in categories of music and art (18%), helping your community (16%), and digital media (15%). Organizations that offered opportunities for youth participation were asked what approaches they used (from a list of 12 possibilities identified through author participation in virtual *My CHI. My Future.* conversations) and how successful they were (on a scale from 1-4, with 1 being *not at all successful* and 4 being *highly successful*). Organizations utilized multiple strategies (M = 3.9, SD = 2.8) with a range of success (Table 1).

Table 1: Remote implementation strategies used and their perceived success by practitioners who used them

	N	% that used strategy (N = 126)	% of users that found strategy highly successful
Synchronous activities			
Structured online workshops or classes	86	68.3%	36.1%
Opportunities for youth work / community service	49	38.9%	47.1%
Access to mentor-led activities via live stream (social media)	37	29.4%	25.7%
Access to peer-led activities via live stream (social media)	11	8.7%	36.4%
Asynchronous project-based work			
Physical activity kits for projects (to be picked up)	49	38.9%	44.9%
How-to videos for self-directed exploration	48	38.1%	11.4%
How-to guides (printed) for self-directed exploration	27	21.4%	18.5%
Spaces to share and observe			
Virtual connections to people/places (e.g., tours, speaker series)	47	37.3%	47.8%
Online youth showcases (e.g., performances, gallery space)	33	26.2%	48.5%
Online youth challenges (e.g., talent shows, art contest)	27	21.4%	48.1%
Synchronous discussions/conversation			
Access to adult mentors through online/phone office hours	47	37.3%	25.5%
Peer- and topic-based town hall meetings or group chat	29	23.0%	34.5%

Structured online workshops or classes were most common (68%), as organizations translated existing in-person programs to an online format using Zoom or other video conferencing tools. Also common were work and community service programs for youth, physical kits that youth could pick up and work through at home, and asynchronous videos for youth to work through projects. Close to 50% of organizations who used the common strategies of physical kits and work/community service opportunities identified them as particularly successful. Both approaches have a focus on equity (i.e., opportunities that do not require high speed internet and where youth are paid for their participation) and were highlighted in open-ended responses asking providers about best practices. One organization wrote that "providing garden kits that they could tend to at home was engaging for both the youth and their families" and another provided kits with a mask-making activity, saying, "youth [were] able to send us a photo of their completed project…[and] some youth create more masks for their family members and others." City funding to pay youth for participation in remote jobs and internships was identified as critical "for youth who desperately need pay and stipends."

Less frequently utilized but with higher reports of success were opportunities that allow youth to contribute, share, and observe, including connecting them to people and places such as virtual tours or expert speaker series, and opportunities for youth to create and showcase their own work and see that of others through contests and showcase opportunities. This aspect of youth voice and choice was emphasized in open-ended responses, "Allowing the youth to be part of the program planning, scheduling and designing process."

Remaining challenges and plans for the near-term future

Nearly all of the organizations (90%) planned to offer virtual opportunities during the school year and 40% were planning non-digital remote approaches, but even while organizations adapted offerings in creative ways, getting the word out was a struggle. For example, one person shared: "We did offer our live streaming event interviewing music industry executives [over the summer], but unfortunately, it didn't really reach youth." Almost a quarter of organizations (22%) did not have their own physical space and relied on locations in the community, most of which remained closed, to both offer and advertise their programs. The majority of organizations (80%) had existing relationships with Chicago Public School (CPS) and depended on these relationships to connect with youth and broaden their reach, but new mandates and requirements due to the pandemic made it such that most had lost this connection and there was confusion about new processes required for new partnerships. From a list of 18 organizational needs to support youth and families (including financial, personnel, and technology supports), clarity of information from CPS was the most frequently identified (61%), followed by technology equipment and hi-speed Internet for families (51%) and information regarding basic services (51%). Brokering information was a common theme in open-ended responses about community needs, “Wellness checks to the youth and families work very well. Families and youth shared what they were going through and were able to ask about the food pantry and other essential needs resources.” Also of interest was professional development in remote facilitation (48%) and equity and social justice (45%).

Discussion

In this paper, we share results from a survey of 126 youth-serving organizations in the City of Chicago as they reflected on the first wave of pandemic-disrupted service while preparing for the 2020-21 academic year. While these organizations represent a range of communities, organizational size, and ages served, a limitation of this study is that we only heard from organizations that have the capacity to complete a survey during this stressful time. Nevertheless, results offer a more complex picture of organizational resilience during the pandemic than might be suggested. Findings suggest several directions for design and research, as organizations continue to offer opportunities remotely and in preparation for future events. First, providers have a lot to share and are struggling to find the information they need. Opportunities for youth-serving organizations to exchange ideas about what they are learning has the potential to increase professional capacity, strengthen community networks, and crowd-source connections to up-to-date information and resources. Second, approaches to engaging young people that providers found to be more successful align with informal learning literature that emphasizes youth voice and brokering connections to meaningful opportunities (e.g., Ching et al., 2015; Montgomery, 2017). Examples of how providers are doing this remotely can inspire new technologies to better support organizations to engage in synchronous and asynchronous communication and experience design. Finally, youth-driven experiences were less frequently implemented but rated among the more successful strategies. Including young people in this research is an important next step to understanding conditions and strategies *they* find engaging and to invite them as co-designers of potential future experiences, including opportunities for youth to take the lead remotely.

The Disciplinary Nature of Science Teachers' Talk in the Process of Formative Assessment Design

Abstract: Formative assessment is an important instructional practice in K-12 science classrooms and yet continues to be challenging for teachers to enact. Designing science-specific formative assessments requires teachers to leverage their understanding of science ideas, their understandings of how student understanding of content develops over time, and their understandings of pedagogical strategies that draw out student thinking. In this study, we analyze teacher conversations during the process of formative assessment co-design during a two-year professional development. We found heterogeneity in teachers' contributions both within and across meetings as teachers engaged in co-design. We document how the structure of the professional development process surfaced varied contributions on the part of the teachers, which led to the collaborative design and revision of a formative assessment task.

Introduction

There exists near-consensus in the science education community that formative assessment, or the practice of listening and attending to student ideas during the course of instruction, are essential elements of effective and equitable science learning & teaching (National Academies of Science, Engineering & Medicine [NASEM], 2018). Facilitating formative assessment successfully can be challenging for science teachers to implement (Sezen-Barrie & Kelly, 2017). It relies on science teachers having a repertoire of classroom practices that center student ideas and experiences alongside the science students are learning. Researchers have emphasized links between teachers' formative assessment practices and knowledge of how student ideas develop in a domain, or pedagogical content knowledge, in addition to their content knowledge of a discipline and general pedagogical knowledge of teaching strategies (Magnusson et al., 1999). However, how these different facets of "professional competence" (Blömeke et al., 2015) are represented within a professional learning community remains unexplored. In this paper, we investigate the distributed expertise of science teachers' knowledge base for formative assessment through an analysis of their conversations during a professional development on formative assessment task co-design.

Theoretical and conceptual framing

Teachers bring a wealth of experiences and resources to their learning (Putnam & Borko, 2000). As teachers make sense of new teaching practices, they draw on personal, social, and material resources to interpret these new practices and make necessary shifts to their instruction (Spillane et al., 2002). In professional learning settings, teachers' varied experiences across science teaching and learning become resources for the co-design of new instructional tasks and provide opportunities for learning (Penuel et al., 2007). This paper considers the ways in which the distributed expertise (Hutchins, 1995) of teachers in a professional learning community supported teacher development of formative assessment tasks. The cognition of groups is constructed through interactions between internal structures of individuals within the group and the structures external to the group that mediate their work (Hutchins, 1995). In the next sections, we describe the external structure of the formative assessment design cycle, which guided our approach to professional development, and the important internal cognitive resources that teachers may draw on within this cycle to co-design formative assessment tasks.

Formative assessment co-design as a site for teacher learning

While formative assessment tasks are often designed away from the school site by curriculum developers and measurement specialists (Bennett, 2011), the very teachers that enact them can contribute to their design (Ainsworth & Viegut, 2006). We have used co-design as an approach to develop common formative assessment tasks with teachers (Furtak, 2012). These tasks are common in that all teachers enact the same task in their classrooms, but they also create a common frame of reference in which to interpret student thinking. This supports teachers to clarify their own understanding of the content, clarify the goals for student learning, and forge professional consensus around the quality of teaching and student work (Danielson, 2007).

Our project followed an iterative, five-step professional development cycle called the Formative Assessment Design Cycle [FADC]. The purpose of this cycle was to situate teachers' work in their own classrooms and to draw upon their knowledge and experiences to develop, enact, and revise a set of common formative assessments (Furtak, 2012). In this cycle, teachers *Explore* student thinking in a domain, *Design* instructional tasks for drawing out student thinking, *Practice* using those tasks, *Enact* the tasks and collect evidence of student learning in the form of student work and video, and then *Reflect* upon that process of enactment and make necessary revisions to the formative assessment task.

Science teachers' personal resources for formative assessment task co-design

Teachers enacting formative assessment need to complement their deep knowledge of formative assessment strategies and domain-specific content with understanding of how students learn in a given domain, the common everyday experiences they are likely to leverage as they learn, and strategies for supporting students as they advance in their understandings (Bennett, 2011). Research on science teachers' formative assessment practices highlight key personal resources that they may draw on as they as work to collaboratively develop science-specific formative assessment tasks. These resources include their understanding of the science content (Forbes et al., 2015) and their beliefs about how students learn in science (Box et al., 2015). We add teachers' domain-general practices, such as stop lighting, which are common school-based formative assessment practices.

In this paper we consider how science teachers, with heterogeneous experiences relative to different science ideas, science teaching, and pedagogy in general, contribute to the process of co-design of a formative assessment task during a two-year professional development program. Specifically, we ask (1.) What personal resources did teachers draw on during the process of formative assessment co-design? (2.) How did the heterogeneity of teachers' contributions relate to the co-design of a formative assessment task?

Method

We explore data gathered in a two-year study in which a department of high school biology teachers collaborated with university researchers to co-design, enact, and revise a set of common formative assessment tasks about natural selection. The study was conducted for two years on-site with a team of biology teachers at large suburban high school of a large city in the western US. Seven teachers participated in the professional development meetings across the two years of the study with a range of teaching experience (3-29 years) and varied expertise in science.

Content and curriculum

The content focus of the professional development was evolution by the process of natural selection. Natural selection provides rich opportunities for teachers to explore the myriad ideas students have about how populations of organisms and individuals change over time (Anderson et al., 2002). At the beginning of the study, teachers did not plan together, and there were few activities shared among teachers and no common assessments.

Sources of data

Sources of data include videotapes made during each of the on-site professional development meetings, each about 60-90 minutes long, supplemented by field notes and drafts of the formative assessments. We trace the co-design of one common formative assessment task. Although teachers and researchers developed several formative assessments during the study, we chose to focus on the trajectory of a single assessment task, *Natural Selection vs. Individual Change* for two reasons. First, teachers were central in problematizing and developing this formative assessment. Second, teachers used artifacts of practice, in the form of written drafts of the assessment and videotapes of enactment, to reflect upon and revise the assessments for use in their classrooms during the project. We reviewed content logs and identified all instances of discussion around the task and created detailed transcripts. Overall, we sampled 125 minutes of videotape across 5 professional development sessions. The transcripts corresponded with video excerpts varying in length from 13 minutes to 34 minutes, with a mean length of 25 minutes and median length of 24 minutes.

Data analysis

We segmented transcripts of the videotaped meetings into speaking turns and gave each segment a set of tags for length and speaker. We developed a coding system to categorize talk turns as having a focus on disciplinary ideas, discussions specific to the teaching of those ideas (science teaching), or more general teaching topics (general pedagogy). Three of the authors independently coded all transcripts (disciplinary ideas: agreement=89%, r= 0.58, K=0.53; science teaching: r=0.43, K=0.38; teaching: r=0.62, K=0.59; transitions: r-0.31, K=0.23). We then discussed and adjudicated all disagreements.

Results

Our coding of the discussions reveals heterogeneous contributions to the conversation about task design. Figure 1 illustrates how each of the teachers and the facilitator (Carrie) had similar contributions in terms of the talk within the meetings, although their contributions were often in different domains, illustrating both the heterogeneity of teachers' contributions and their own experiences in science and teaching. Furthermore, the emphasis on working out the details of the disciplinary ideas around natural selection was reflected in the contributions of each of these participants during the design phase, and then equally transitioned to discussions focused on science teaching during the reflect and revise phases of the study.

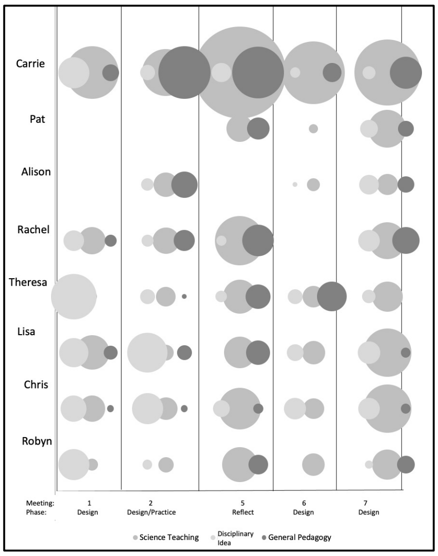

Figure 1. Bubble plot of relative proportion of teacher utterances.

Distribution of talk across the FADC

We next investigated the ways in which the types of talk and teacher contributions were distributed across co-design activities in different meetings. We mapped the distribution of the three types of talk segments across time for each of the meetings, which revealed differences in teacher talk between meetings focused on Design and Reflection (which includes revision of the task). When teachers talked about designing the task, they engaged in sustained conversations about disciplinary ideas, interspersed with conversations about science teaching, which involved turning those science examples into a formative assessment designed to get at student thinking about phenotypic variation and whether it was a result of natural selection or individual change. For example, in the following segment the teachers were working out an example for the task that asked students if rabbits' fur changing color in different seasons was an example of individual change or natural selection. Chris initiated a conversation about the science behind the example:

Chris:	Does anybody know about the rabbit, what if a rabbit had a baby in the winter?
Theresa:	But they are always born in the spring. [Laughter] Because they are hibernating in the winter.
Chris:	What if they had a baby in the spring and then you took the baby and put it in snow.
Alison:	In an environment, so you took it -
Chris:	Yeah, if you took out of the in the summer and stuck it in the freezer would it turn.
Rachel:	I believe you couldn't because there have been experiments you put ice packs on them.
Theresa:	Oh yeah, I've seen that.
Rachel:	It's an enzyme, it's a cold
Lisa:	That's one of the ones in the scientific method [referring to the textbook]
Chris:	I didn't know that.
Theresa:	Don't put the bunnies in the freezer [Laughter]

In conversations such as these, the teachers drew on each other's knowledge of the process of natural selection to better work out the mechanisms of change in the specific example of the arctic hare. While most of the talk in developing the assessment focused on disciplinary ideas during the reflection phase, teachers' conversations shifted to a focus on general pedagogical strategies and science teaching, with interspersed discussions on the science content as the assessment was revised. During meetings in these later phases of the design process, teachers watched a video of Theresa leading her class in a discussion around the examples and engaged in conversations about general pedagogy and science teaching early in the meeting, stimulated by the video, which then led into a sustained conversation later focused on a possible revision of the task. There are only a few talk turns dedicated to disciplinary ideas exclusively. Throughout these conversations, we observed teachers' different contributions to discussions as they raised questions about the nature of different aspects of natural selection, the ways it was represented in the task, and how they would lead the task with students.

Discussion

The analysis described in this paper provides evidence that the heterogeneity of the contributions by the group during the process of formative assessment task co-design provided opportunities for teacher learning about disciplinary ideas and practices, the students they teach, and pedagogy in general. Rather than looking at the knowledge within teachers' own minds, we explore how their contributions can productively contribute to the design of a task. In this way, we shift the focus from the knowledge teachers need to enact a task, to the ways in which their varied expertise in science and in schools contributes to formative assessment design. The majority of the changes to the formative assessment grew directly from teachers' conversations about science content, as well as student ideas and instructional approaches to teaching that content. Research models, such as research + practice partnerships (Coburn & Penuel, 2016) that include various stakeholders can further support these learning opportunities for teachers as they engage with various forms of expertise in the co-design process.

“I Kept Going because We were Close”: Deepening Understandings of the Relational Work of RPPs

Kristina M. Stamatis, University of Colorado Boulder, stamatis@colorado.edu
Ung-Sang Lee, University of California Los Angeles, ungsanglee@g.ucla.edu

Abstract: Research Practice Partnerships (RPPs) have emerged as a means of pursuing research that is of immediate consequence for K-12 U.S. education. While theorists have acknowledged the need to develop relationships between practitioners and researchers in RPP settings, questions remain about the ways that relational work can facilitate equity and support practitioner agency and engagement. In this paper, we look to feminist and sociocultural perspectives to examine two RPPs in the mountain west United States and the ways that practitioners and students expressed relational work as central to their engagement in the projects. We found that participants who engaged deeply over long periods of time with these RPPs felt mutual trust and personal connections with researchers, colleagues, and peers that led to their continued and deepened engagement.

Major issues

Over the past decades, research practice partnerships (RPPs) have emerged as a means of pursuing research that is of immediate consequence for K-12 U.S. education. Defined as “long-term collaborations between researchers and practitioners that leverage research to address persistent problems of practice” (Henrick et al., 2017), RPPs have extended design implementation research principles intended to include practitioners in the development of research questions and interventions. Because of their relative novelty and the extended timeframe that many RPPs require in order to successfully build equitable partnerships with practitioners, questions remain about how to effectively implement, assess, and sustain the success of these kinds of projects. A number of researchers have taken up these questions in order to develop parameters to assess and evaluate RPPs, while continuing to theorize about the parameters needed to define successful RPPs (e.g., Coburn, 2003; Henrick et al., 2017; Morrel et al., 2019; Penuel, 2019). In this paper, we focus on relationship building as a common feature across literature on successful RPPs and explore the ways that feminist perspectives on relationships can expand equity and extend the sustainability of these partnerships.

Theoretical approach

In this paper, we take up sociocultural, sociohistorical, and sociocritical perspectives on learning and human action that emphasize the social, cultural, historical, and political contexts of human activity . We understanding learning ontological, a process of development in relation to one’s self and others (Lee, 2017), and therefore centralize relational practices in our research. Additionally, we are concerned with the histories of the communities and participants with whom we collaborate and we take a critical stance toward the ways that historically marginalized communities have traditionally been positioned with deficits in educational spaces. Taking up an expansive understanding of learning means that we work to decenter whiteness, developing research-based solutions in educational settings that take into account the cultural funds of knowledge (Moll et al., 1992) of our participants. These approaches have direct implications for the ways that we build and work within research practice partnerships (RPPs) as well as beyond them.

Research practice partnerships

To conceptualize research practice partnerships (RPPs) in education, we rely on literature that describes the importance of interactions between researchers and practitioners as central to developing research that addresses the consequences of implementing educational policies and learning standards. For this analysis, we focus on RPPs grounded in design research and collaborative design of interventions by practitioners (teachers, administrators, and other district stakeholders) and researchers (Coburn et al., 2013). These authors described design research as a form of educational research that aims “to build and study solutions at the same time in real world contexts” (p. 8). In our work, we see solutions to longstanding issues in education as deeply intertwined with creating more equitable, representative, and just systems for all students. Because of these commitments, we study RPPs as a potential vehicle for articulating and addressing issues that have created opportunity gaps for historically marginalized students and students struggling with poverty (Carter & Welner, 2013). Coburn and co-authors (2013) wrote that RPPs that focus on design research tend to focus on long-term, place-based work so that designed interventions account for context. They emphasized that collaboration is a core tenet of these projects with practitioners' perspectives and expertise brought to bear on each stage of the process from defining the problem or challenge to assisting with adaptations and revisions.

Relationships as core design principle

Because RPPs are long-term partnerships, they often develop over a number of years and have proven difficult to assess (Coburn et al., 2003). However, researchers have begun to take steps to align the differences between RPPs by developing frameworks for assessing both their effectiveness (Henrick et al., 2017) and the ways their designed interventions and infrastructures can scale (Coburn, 2003; Penuel, 2019). Across each of these frameworks, relationships have been identified as a central practice to support both the initial development and continued adaptation of interventions within individual contexts. Additionally, a number of researchers have discussed the need to build and maintain relationships in design-based RPPs in order to identify the boundaries of collaborators roles and the ways that collaborators will participate in the design processes (e.g., Penuel et al., 2015). As Henrick et al. (2017) explained, effective partnerships are dependent upon "building trust and cultivating partnership relationships" (p. 5). While much of the research on RPPs appears to position relationships between practitioners and researchers as a means of addressing "the wide gap between the worlds of educational research and practice," (Penuel et al., 2015, p. 182), we question the ways that expansive feminist perspectives might expand and aid the development of relationships within these kinds of design environments.

Expanding approaches to relational work

Learning in relation to others is foundational to sociocultural theory. Similar to literature on RPPs, feminist theorists maintain that research cannot be successful without personal investment from both participant and researcher (Fonow & Cook, 1991). However, a feminist approach to also centers "friendship, intimacy, and trust" (Davids & Willemse, 2014, p. 1) and works to understand "the social through ourselves, [entering] a subjective, cultural space that is mediated *through* the researcher" (Olive, 2012, p. 75, citing Probyn, 1993). We take this perspective as an expanded view of relationships. While research often focuses on relationships as a means of developing successful RPPs (e.g., Henrick et al., 2017), we rely on critical feminist perspectives that support understandings of RPPs not just as long-term projects, but as long-term relational work extending beyond initial project goals. We see this perspective as essential in building RPPs that work toward equity and justice because we believe that self-reflection from researchers and practitioners is essential in understanding the ways that lasting problems of practice are tied to the social, historical, and cultural contexts in schools.

Methods

Participants and context

To examine the way that feminist approaches to relational work in RPPs support practitioner understandings of the RPPs in which they participate, we looked across two school-based design partnership projects in the Western region of the United States.

The Compose Our World (COW) project was a multi-year research practice partnership to collaboratively design and implement a year-long 9th grade English language arts (ELA) project-based learning (PBL) curriculum with nearly fifty practicing teachers and fifteen researchers. This paper focuses on relational work between researchers and three teachers who were part of the initial co-design team and continued to participate in research activities (i.e., participating in additional studies, supporting data collection, and publishing with researchers) even after the COW project had ended. The teachers, Elizabeth, Abby, and Evie, worked together as 9th grade ELA teachers at a rural high school and each described themselves as veteran teachers who had been in the classroom for at least ten years at the start of the study in 2015.

The Student Technology Action Research (STAR) was an RPP in collaboration with practitioners, students and other stakeholders at an urban university-affiliated high school. This project centered the ways that historically nondominant high school students were able to leverage community cultural wealth (Yosso, 2005) to participate in the participatory design (Bang & Vossoughi, 2016) of curriculum and practices intended to integrate meaningful technology practices into their school ecology. This paper focuses on relationships between one teacher partner, several students, and the researcher as they built relational practices that honored the diverse perspectives and cultural assets they brought to the design process.

Data collection and analysis

Each project took place over five years and used qualitative and ethnographic methods to collect observational fieldnotes, audio and video recordings, designed curricular materials, and student artifacts. Additionally, each researcher completed semi-structured interviews with participants to develop understandings about participants' interpretation of the relationships and relational practices that mediated the collaborative design process. Each project relied upon a design-based research model in which data collection and analysis was conducted while practitioners and students implemented designed materials (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). We also conducted retrospective analysis, using qualitative methods (Miles, Huberman, & Saldana, 2014) to code data, identify themes about relational work, and conduct member checks to establish trustworthiness. Cross-project analysis was then done through dialogic spirals (Kinloch & San Pedro, 2014) to compare themes and identify representative examples and counterexamples.

Findings

Feelings of closeness trust aided collaboration

Across projects, we found that when practitioner and student collaborators were asked their investment in the research partnerships, they nearly always referenced feelings of closeness and mutual trust with regard to their co-designers. These feelings emerged in interviews, as participants voiced growing confidence and closeness within the design teams. In the twelve interviews (six from each project) analyzed for this paper, each participant repeatedly noted that they chose to continue collaborating because of the investment they felt had been made by researchers, not only in their classrooms, but also in their personal lives and development as teachers and learners. For example, Elizabeth, who felt she had been distant with colleagues because of her husband's medical needs, explained that becoming a co-designer gave her a way to build relationships with her colleagues while also working to improve her practice, rather than in time spent outside of her classroom.

> I just wanted [my colleagues] to recognize that there's a lot of things going on with me *and* I can connect. I can be vulnerable and I can show weakness and be self-critical, but that being smart is also part of my identity… I didn't consider myself a leader… until getting involved with COW because you all thought I had good things to say.

She went on to emphasize that her participation on the project offered her opportunities to see herself as a leader. When asked how she had decided to continue participating in the project for five years, particularly given her time constraints, Elizabeth replied, "For some reason I decided I was just going to trust you all. And the more I trusted you, the more I felt valued, like you also trusted me...I kept going because we were so close." For Elizabeth, the relationships fostered in the project were both personal and professional; ultimately the personal feelings of closeness were key to her continued investment in the RPP.

Honoring funds of knowledge led to deeper relationships

In her chapter introducing funds of knowledge, Gonzalez (2005) described the phenomena of *confianza* or mutual trust as key to developing social relationships that attended to the intersections of cultural knowledge (see also Velez-Ibanez & Greenberg, 1992). Across projects, participants from historically marginalized backgrounds expressed feeling deeper investment when they felt they were given opportunities to question dominant narratives in curricula and to bring their own knowledges to bear on the designs. This was especially true of the student co-designers in the STAR project, who were engaged in creating an e-portfolio system that would shift student evaluation away from the traditional models to those that better represented their linguistic, political, and aspirational assets. In collaborating to design the new system, students expressed feeling more autonomy and agency, and explained that their relationship with the researcher, who brokered (Ching, Santo, Hoadley & Peppler, 2016) access to broader academic and social domains related to their expressed interests and assets, played a critical role in their participation in co-design. Ultimately, students expressed that their participation as collaborators supported them in deepening their interest in school because they saw their ideas directly represented in the changes that took place in their learning environments.

Personal relationships as extensions of research

Both of the RPPs examined in this paper resulted in extended work beyond the initial RPP timeline. We each found that our relationships had led to an investment in research from teachers that led to new questions and new kinds of design partnerships, even after the larger RPP work had ended. Each of the three teachers who participated in COW went on to develop their own questions and partnered with small groups of researchers to explore these questions in their own classrooms. Similarly, researchers and teachers from STAR sought and won additional funding in order to continue co-designing school process and anti-racist practices with students and teachers. In each project, co-designers identified the personal relationships they had built with individual researchers as key to their continued engagement. Abby, from the COW project, explained, "I guess I just saw what we were doing as so meaningful…Why wouldn't I try and continue?" She went on to explain that her feelings were in large part due to the personal investment of researchers. "They've become more than colleagues, they're friends."

Discussion

Researchers have long acknowledged the complications of attending to power dynamics while working in collaboration with practitioners in RPPs. However, questions remain about how to attend to issues of equity and representation in these collaborations. Feminist perspectives on research—"emphasizing such issues as reflexivity, relations with 'subjects,' representation, and voice, particularly to concerns about power" (Monk et al., 2003)—call for attending to relationships as core to successful consideration of participant perspectives. In applying these feminist perspectives to our experiences in two long-term RPPs, we found that participants who continued to engage in long-term partnerships felt their own funds of knowledge and personal experiences were honored and valued both by researchers and by their colleagues and peers. When partners felt valued, they invested more in the projects, and as relationships grew, these partnerships extended beyond the boundaries that had initially defined our roles and goals as RPP collaborators (Penuel et al., 2015). Our research suggests that feminist notions of relational work has potential to expand understandings of how to support practitioners and students to engage in RPPs and the ways in which RPPs can act as vehicles for equity and educational change.

Seeing Learning Sciences Research as Modeling

Jeremy Roschelle, Digital Promise, jroschelle@digitalpromise.org

Abstract: Researchers in the Learning Sciences take two prevalent stances: research as building theories or as developing designs. The connection between theories and designs is most often filled in by methods, but an alternative stance is possible: research as improving models. The modeling stance seeks parsimonious, useful, illuminating descriptions of learning activity systems. Models can help us understand and express how variability (in all its forms) plays into, is enacted during, and results from designed learning activities. Building models often requires employing multiple theories, methods, and design elements; a modeling stance recognizes that our research often elaborates a multi-level systems view. An explicit modeling stance may lead to developing descriptions of complex systems, inviting multi-stakeholder teamwork to improve these systems, integrating advances in learning analytics and educational data mining, and adding to ability of learning sciences research to tackle challenges at scale.

Introduction: Beyond theory and design

What do learning scientists do? Often our self-descriptions begin with broad ambitions. The ISLS website announces that we are "dedicated to the interdisciplinary empirical investigation of learning as it exists in real-world settings and to how learning may be facilitated both with and without technology." Learning sciences has is an applied science or in the terms of Pasteur's Quadrant (Stokes, 2011), a pioneering science. As a pioneering science, we aspire to use-oriented, foundational, impactful research. And yet what we report may be constrained by what we can publish. The opening description of the aims of the Journal of the Learning Sciences states:

> JLS provides a multidisciplinary forum for research on education and learning that informs theories of how people learn and the design of learning environments. It publishes research that elucidates processes of learning, and the ways in which technologies, instructional practices, and learning environments can be designed to support learning in different contexts.

Note that the requested types of contribution have theories and designs as the two clear anchor points. In a recent handbook chapter, Kali & Hoadley (in press) provide a diagram (Figure 1) that locates Design-Based Research as an epistemic game that connects theory-oriented and design-oriented work. DBR has been subject to critique, e.g., for missing or idiosyncratic argument structures (Kelly, 2004). Some have also observed that design-based research does not adequately address challenges of scaling up, leading to self-critique within the field (e.g. Wise & Schwarz, 2017). This short paper suggests an alternative conception of our work: research as modeling. Modeling also occurs at a middle level between abstract and concrete and between simple and complex. Unlike design-based research, it places greater accountability on developing a logic model or theory of action that can account for variability throughout a learning activity system. This is common in much work that learning scientists do, but we underemphasize our craft of modeling in what we report in publications.

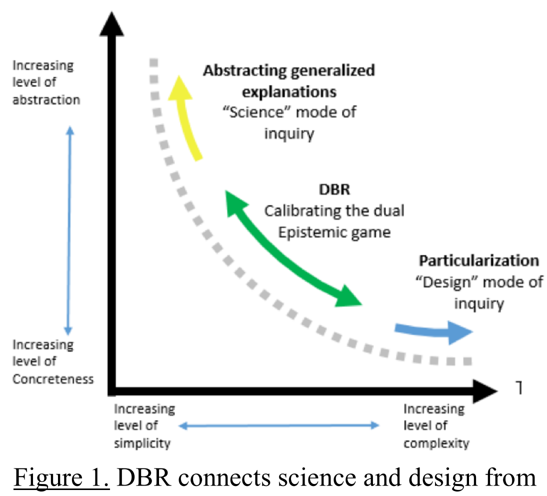

Figure 1. DBR connects science and design from Kali & Hoadley (in press), used with permissions

The aim of this paper is to foster discussion at our society's meeting about how to make the practice of *modeling* complex learning environments a priority pursuit for learning scientists. This could entail both a practice of doing modeling to improve theories and designs, but also a pursuit of models as a useful artifact in their own right. Models can help learning scientists to work with others in teams and that can enable scaling from smaller to larger data sets and from exploratory designs to designs ready for messy, real world contexts. This short paper will sketch what a modeling stance might look like in the learning sciences, discusses the potential significance of giving this stance more prominence, and draws out potential implications for individual learning scientists, for collaborations with other disciplines, and for the kinds of research reports our institutions solicit.

Sketching the Learning Sciences as modeling

The Oxford English Dictionary (2021) defines modeling as: "A simplified or idealized description or conception of a particular system, situation, or process, often in mathematical terms, that is put forward as a basis for theoretical or empirical understanding, or for calculations, predictions, etc.; a conceptual or mental representation of something." Models are useful to scientists because they enable gathering knowledge, forming concepts, clarifying theory, explaining and understanding phenomena, and evaluating truthfulness (Frigg et al, 2020) Modeling, thus, is the art of creating purposefully simple and useful approximations of reality. Credible models organize both knowledge and data to help us reason through a problem without becoming overwhelmed by every factor that could be relevant. Modeling is an iterative process. When we test an approach in expanding contexts, we see additional variation; we realize we need to address it and decide how best to capture and make sense of it. Modeling is purposeful or teleological; we build models to engineer improvement. Modeling is also often collaborative: a shared explanatory structure can make it easier for to integrate multiple perspectives.

What is a modeling stance?

In common with most work in the learning sciences, I suggest that the motivating or driving question for modeling work is to understand how a target population of students learns a complex or challenging subject matter. A tool like Activity Theory invites a modeling stance (see Figure 2, Bury, 2012). The interconnected relationships in the depicted triangles invite a team to look for and map the different interacting elements and processes that together form a learning activity system. In addition, in my experience as a reviewer of research proposals, many projects develop and refine a Theory of Action or a Logic Model, which is a spatial tool for organizing information about all the factors that have a plausible causal relationship to learning. A typical Theory of Action accounts for new inputs to a learning activity system, the training processes and other new resources that prepare teachers to enact it and the learning outcomes that are expected. Many logic models build on Cohen et al (2004). They express a contrast between the new and typical learning activity in terms of what changes among teachers, students and resources in a context. A conjecture map (Sandoval, 2014) can also serve as a logic model. Our field routinely uses models.

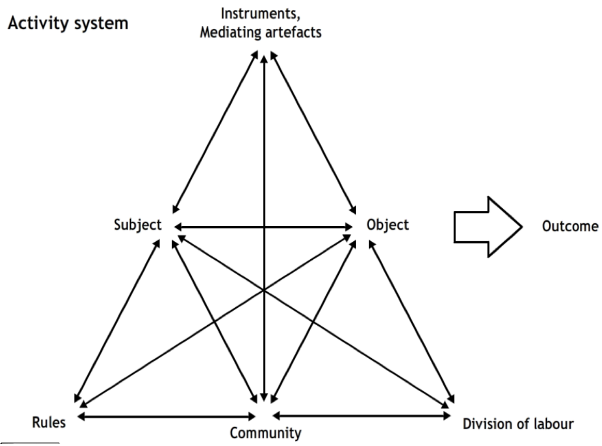

Figure 2. Activity Theory Diagram

The difference between a modeling stance and design-based research may the object of the activity (always in service of an outcome of better learning).

In **model-oriented research**, a more accurate model of how people learn is the *object* of the research; by having a better model, we can explain and predict all the factors that are important to determining the outcomes. A novel design is positioned as an *instrument or mediating artifact* that enables perturbing the business-as-usual model so we can better understand how learning might better take place

In **design-oriented research,** a novel learning design is the *object* of the research; the design is iteratively improved to incorporate what was learned about relevant factors in the learning process. A good model of these relevant factors is a *mediating artifact* that organizes information so that the design can be improved and/or tested with appropriate control of favors beyond the scope of the design.

To explore why this might make a difference, consider other elements of Figure 2. What happens when our community *rules* and *division of labor* are in service of publishing a design or theory? What happens when investigators (*subjects* in this use of Figure 2) are positioned as designers or theorists? My suggestion when the publishable object is only a theory or a design, much learning science competence is rendered invisible. If the publishable outcome could be a better model of learning in a context—a model that is simple enough to be widely re-usable and complex enough to account for the many factors that contribute to learning—I suggest we will make more visible our rules of good modeling building; we will invite a division of labor where different expertise can contribute to anticipating, explaining and predicting how learning may unfold; we may invite investigators who don't see themselves as theorists or designers, but have valuable contributions to make nonetheless.

An example may help:

Imagine that a newly available 5G sensor technology allows students in hybrid classrooms (some students are remote, some are together in a classroom) to more smoothly observe the presence of others and shift among different configurations of small groups.

With a theory stance, one researcher sees this as a system which could advance theories of embodied cognition, as the new sensors capture and represent gesture in new ways. With a design stance, another researcher sees opportunities to create new supports for classroom argumentation, based on allowing students to quickly change groups as they share ideas. With a modeling stance, a third researcher sees that in a data set emerging from early field studies, participation in the groups varies quite a bit – perhaps in ways that reflect who is remote and who is in the classroom -- and begins to wonder: in these patterns we see at scale, which kinds of variation should we focusing on? what different theoretical ideas might we need to explain all the variation we see? What kind of structured diagram would allow practitioners, developers and researchers to work together to make sense of what happens when classrooms use this technology? What structure provides the best tradeoff between simplicity and complexity and between particularity and generality? The stance may make an important difference, therefore, in how we frame our a project, what expertise we recruit, and what work gets done.

What are key objectives in modeling work?

As a discussion starter, I suggest some characteristics of model-oriented research below.

The system perspective is elaborated. Researchers taking a modeling stance elaborate a description of what makes up the relevant learning system. This involves *not* taking the designer's word for what the system is nor taking the learning environment for granted, but rather probing the other local resources, capacities, practices, agencies, and other forces that enter in to how the system is enacted and how it is adapted. Improvement Science, for instance, takes as a key practice "seeing the system" with useful but not too much detail (Carnegie, n.d.).

Multiple levels are considered. A modeling stance requires thinking about different levels of granularity and timescales. In one precedent, learning scientists talk about the meso-, midi- and micro-scales of learning activity. For example, Rogoff (2008) talks about cultural, social and personal "planes" of a learning activity. Learning scientists also think across different timescales, conceptualize interventions with different granularity, or developed nested systems of scripts to guide collaborative learning (references omitted to conserve space).

Multiple theoretical and design elements are integrated. In modeling complex learning environments, it is often the case that no one theory provides a comprehensive set of factors and relationships that is suitable for accounting how learning occurs or varies. Likewise, designs that scale incorporate multiple design factors (Roschelle et al, 2021). The modelling work brings heterogenous elements together in a comprehensive view, where theories are elaborated to fit the particulars of designs and implementations.

Logic models support fitting data. In modeling work, a theory of action is not just to organize the processes of evaluating a novel approach to learning, but also a guide to instrumenting all the relationship that need to be measured. As data comes in, we can see if expected relationships are present and strong, or whether the model needs to be modified to better predict and explain the phenomena. New theories or previously uninspected aspects of the design may need to be added to the model to better explain how learning unfolds. The process of fitting data is the key driver of model improvement.

Scaling research enables observing, making sense and adapting to variability. As others have pointed out (e.g. Coburn, , a large *n* is not necessarily the goal of scaling – for example, we should care about the depth of the innovation and shift of ownership (Coburn, 2003). Scale can also be an opportunity to understand and work with learner variability and variable implementations of teaching and learning processes. A modeling stance would collect data at scale not only to expand impact or improve the implementation, but also because we need to study learning at scale to get better at modeling. Gomez et al (in press) make the case, for example, that many issues of diversity, equity and inclusion really only emerge when a suitable scale of data is available.

Each version of the model serves as a parsimonious boundary object. Returning to the idea that the modeling stance involves multidisciplinary teams, success arises when a model is a useful common ground for conversations that bring together different roles and varied expertise. A good model gives each participant's perspective a place, but also enables a team to see the elephant and not just touch their own leg of the elephant.

Rigor is pragmatic and socially-constructed. Classically, rigor is in service of making a strong causal claim and eliminating threats to validity (e.g. in an RCT). Rigor in ethnographic or descriptive research can be about thoroughness and care in accountability to rich data – avoiding misrepresenting or overlooking phenomena. Although a modeling stance may incorporate aspects of rigor from these approaches, my sense is that the quality of modeling derives from contributions to a pragmatic goal of a community. As models are simplifications, methodological perfectionism nor empirically completeness are best criteria for rigor. A rigorous model should help a community pragmatically to organize its progression of inquiries to address a challenge.

Potential implications for the Learning Sciences

The learning sciences describes itself as publishing advances in theory and design. Yet, improving learner outcomes requires a middle ground between abstract and concreteness, as well as between generality and particularity. Design-based research is in the middle, but outputs a design. An alternative stance would produce models of complex learning phenomena. The field could consider how making modeling a priority at three levels:

- **Professional.** If our professional community were to better recognize individual contributions in making and using models, would that clarify what learning scientist do and open up additional career growth possibilities for early and mid-career scholars? Does this open opportunities for learning scientists who are not abstract theorists nor innovative designers, but are still exceptionally good at studying learning in all its glorious variability in complex contexts?
- **Scientific Community.** The International Alliance to Advance Learning in the Digital Era brings ISLS and learning analytic, educational data mining, learning at scale, and other scientific communities closer together. If learning scientists saw improved modeling as a core contribution (alongside advancing theories or designs), might that allow us to work with colleagues in other disciplines who build models? On a smaller scale, when multi-disciplinary teams form, would a focus on building shared models help the teams work better together?
- **Institutional.** Our journals and conferences more easily feature advances in theories, designs and specific research methods then they do contributions to our practices of modeling complex learning environments. We also often aspire to doing more in terms of diversity, equity and inclusion and we aspire to having impact at scale. Would considering modeling as an institutionally recognized form of scholarly contribution help us advance these aspirations?

The Invisibility Issue: High School Students' Informal Conceptions of Everyday Physical Computing Systems

Gayithri Jayathirtha, Yasmin Kafai
gayithri@upenn.edu, kafai@upenn.edu
University of Pennsylvania

Abstract: While making physical computational artifacts such as robots or electronic textiles is growing in popularity in CS education, little is known about student informal conceptions of these systems. To study this, we video-recorded think-aloud sessions (~10 minutes each) of 22 novice CS high school students explaining their understanding of everyday physical computing systems and qualitatively analyzed transcripts and student drawings for their structural, behavioral, and functional understanding of these systems. Most students identified the presence of programs in making these systems functional but struggled to account them structurally and behaviorally. A few students pointed out probable programming constructs in shaping underlying mechanisms, drawing from their prior programming experiences. To integrate these systems in computing education, we call for pedagogical designs to address the invisibility of computation—both of structural interconnections and of program execution.

Introduction

Physical computing systems (PCS) which involve microcontrollers, inputs, and actuators are used for designing art installations and robotic systems that can interact with the world (O'Sullivan & Igoe, 2004). As computing education grows in K-12 classrooms, these systems are being adopted across a variety of learning contexts. Novices' extensive user experience with everyday PCS may provide productive informal conceptions about these systems—what constitutes these systems and the mechanisms to realize observed outcomes. Indeed, one hope in using PCS in education is that in constructing these systems, learners will draw from their experiences as users, thereby transforming computing learning from being abstract to relevant and concrete (Przybylla & Romeike, 2014). However, relatively few studies have explored how novice learners interpret everyday PCS.

Physical computing systems traditionally consist of input (e.g., buttons and sensors) and output devices (e.g., actuators such as lights, speakers, motors) connected to a central processing unit. The processing unit receives input signals, performs required computation based on a program, and sends appropriate signals to the output devices (e.g., O'Sullivan & Igoe, 2004). PCS can be viewed as consisting of three key dimensions: structure, behavior, and function (SBF) (Bhatta & Goel, 1997). The physical parts of the system make the structural composition, while its overall purpose in terms of inputs and outputs covers the functional aspects; and, the underlying logic that brings together the different components in action accounts for the behavior (Bhatta & Goel, 1997). Extending this framework to understand PCS such as sensor-based stoplights and interactive toys: (1) the *structural* aspects include the different components such as sensors, lights, and the physical connections; (2) the *functional* aspects consist of the roles of each of these components and the overall goal; and (3) the *behavioral* aspects include the underlying logic causing the functionality.

Prior studies around novices' informal conceptions of PCS have touched upon certain aspects of SBF although they shed limited light on students' understanding of the role of computation. For instance, Cederqvist (2020) examined middle schoolers' conceptions of PCS such as car remote key to uncover their structural and functional understanding and found that most of their understanding pivoted around the visible components such as buttons and lights. Pancratz and Diethelm (2020) observed a range of ways in which middle and high school students understood the structural aspects of daily-use PCS such as robotic vacuum cleaners and video game consoles. But, this analysis—limited to uncovering students' structural understanding—revealed very little about how they understood the functional and behavioral aspects of the systems. With PCS making a foray into introductory computing programs, there is a need to examine students' informal conceptions of these everyday PCS, specifically their understanding of computation in shaping their function and behavior.

In this exploratory study, we conducted think-aloud interviews (Ericsson & Simon, 1998) with 22 high schoolers enrolled in an introductory computing class. We provided pictures of two common PCS, a sensor-based stoplight and an interactive plush toy, and invited students to explain SBF aspects of each. In this paper, we answer the following questions: (1) What aspects of computation did students attend to in their descriptions? And, (2) How did these descriptions qualitatively differ across students?

Methods

Context and participants

The study was conducted at a public charter high school located in a large U.S. west coast city. Students were in a year-long introductory computing course, *Exploring Computer Science* (Goode, Chapman, & Margolis, 2012). The class had 38 students, 22 of whom the teacher chose to participate in interviews (14-18 years; 11 female, 11 male; 8 White, 6 Latino/Hispanic, 6 Asian, and 2 African-American). At the time of the interview, they had 10 weeks of Scratch programming experience and this was the only programming experience for most of them.

Data collection and analysis

The first author conducted and video-recorded semi-structured think-aloud interviews (Ericsson & Simon, 1998) where every student was asked to draw and explain their understanding of two different PCS: a sensor-based stoplight and an interactive toy (see Fig. 1)—the former present within a mile radius of the school and the latter, an artifact that students can relate to. Each interview lasted about 10 minutes.

The first author annotated the interview transcripts to capture student gestures and gaze, and drawings to capture related utterances. These were analyzed initially deductively and later inductively (Creswell & Poth, 2016). Deductive analysis involved categorizing descriptions for SBF. Another researcher independently coded 3 student transcripts and drawings (~10% of data), reaching ~90% agreement. After discussing disagreements, the revised codebook was applied, and themes were generated to capture qualitatively differences among descriptions: *simplistic* descriptions that discounted any computation or automated control; *qualified* descriptions that only identified a control mechanism without elaborating on its nature or details, and *constructive* descriptions that involved details about computation such as specific programming constructs. Another researcher then coded 10% of the student responses with the new coding scheme, reaching ~85% agreement. Disagreements were discussed, and the first author coded all the student responses. Each student explanation of every PCS was considered as a unit of analysis in which SBF aspects were identified and a qualitative descriptor was assigned to each, resulting in 6 codes for each student across the two interview artifacts (6 circles per student in Fig. 2).

Figure 1. Interview artifacts: Sensor-based stoplight (left) and an interactive toy bird (right).

Findings

Qualitative variations within student explanations and relationships between SBF aspects revealed three student groups: one with qualified functional descriptions for at least one of the two PCS (n=15; middle group in Fig. 2); another with constructive articulation of computational unit structurally and functionally, and specific programming-related details within behavioral descriptions (n=5; left-most group in Fig. 2); yet another group with simplistic explanations (n=6; right-most group and Jade in Fig. 2).

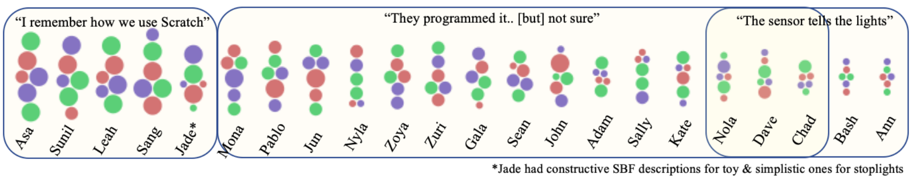

Figure 2. Visualization of student descriptions; red, blue, and green for structural, behavioral, and functional descriptions respectively; small, medium, and large circles for simplified, qualified, and constructive descriptions respectively (all student names are pseudonyms).

"They programmed it…[but] not sure:" Qualified functional descriptions

More than half of the students identified computation in their functional descriptions. They listed an automated mechanism that shaped the overall system functionality (n=15; students with at least one medium green circle, mostly in the middle group in Fig. 2). However, these students struggled to articulate the role of computation in the underlying behavior (medium or small blue circles in Fig. 2). Students identified components such as lights and audio devices as outputs, and the sensors, buttons, and cameras as input devices while describing the system's functionality; most of them (n=9) extended their structural descriptions to acknowledge some form of a computational unit in organizing these inputs and outputs (medium or large red circles in Fig. 2). For instance, Sally identified the control mechanism as a "machine behind [the stoplight]" to coordinate sensors and lights while others acknowledged the presence of a "motherboard," "chip," or a "control panel" structurally.

However, identifying the presence of a computational unit structurally or acknowledging its role functionally did not mean they connected it to system behavior. Many students in this group (first 8 of 13 in the middle group in Fig. 2), informed by their prior Scratch programming experience, thought of computation as distributed across different components such as input/output devices, similar to how sprites are associated with code fragments in Scratch (Maloney et al., 2010). This was evident in Zuri's descriptions of programs as residing in the toy's sensors that will control signals sent to the lights (see Fig. 3, middle). Others (last 5 of 13 in the middle group in Fig. 2) slipped back to simplistic descriptions, barely acknowledging any computation. For instance, Sally, who initially noted the presence of a computational machine controlling the system, dropped it in her behavioral description, and told that the sensors and the lights directly communicate with each other. Overall, students' struggles with articulating the role of computation in system behavior despite identifying its functional presence points to the accessibility of the functional compared to the behavioral or even structural aspects.

"The sensor tells the lights:" Simplistic SBF descriptions

A number of students missed accounting for any computation across their SBF descriptions for at least one of the two PCS (6 out of 22; right-most group and Jade in Fig. 2). The perceptual aspects of the artifacts were the most accessible for learners as they anchored their descriptions around visible inputs (e.g., sensors or buttons) and outputs (e.g., lights and speakers) while leaving out any processing unit. For instance, Bash drew (Fig. 3, left) buttons, a "tape recorder," lights, and wires, and directly connected them to each other without any computing unit. Simplistic structural descriptions led to simplistic functional explanations. In this case, Bash continued to explain buttons as simple electronic switches directly controlling the lights and the "tape recorder." leaving no room for any explanation related to its conditional outcomes based on different degrees of presses.

Simplistic structural and functional descriptions further led to simplistic behavioral explanations. Some students adjusted their simple circuits connecting inputs and outputs to make up for computation-based sensing functionality. For instance, Nola, similar to Bash, thought of the toy in simplistic terms as consisting of buttons, lights, and a microphone connected through wires. When asked about the conditional outcomes, she included computation within her simplistic structural descriptions by adding a set of wires between the buttons and the lights that could send "two different types of signals." She continued to explain the mechanism as one where the button allows for two different kinds of presses and sends different sets of signals for the lights to display patterns. Overall, visible aspects of the PCS such as input and output devices were most accessible to these students, similar to Cederqvist's (2020) observation, and this limited students' ability to see interconnections and computation across the structural, functional, and behavioral aspects of the systems.

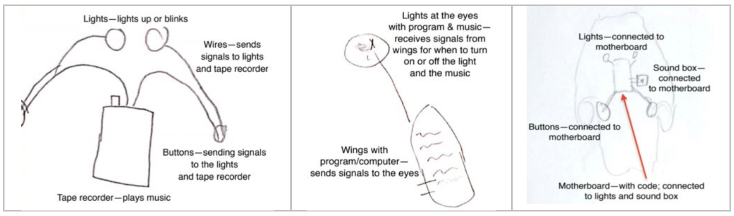

Figure 3. Annotated student drawings: Bash's simplistic connections between the buttons, lights and "tape recorder" (left); Zuri's qualified drawing of wings with computing abilities (middle); Sang's constructive drawing showing "motherboard" connecting the inputs and outputs (right).

"I remember how we use Scratch:" Constructive SBF descriptions

Although most students faced challenges in either identifying or integrating computation into their descriptions, a small proportion of them (5 of 22 in the left-most group in Fig. 2) described specific aspects of computation. They acknowledged the presence of a central processing unit in their drawings and explained its function as receiving inputs and sending signals to respective devices. Further, they drew from their limited prior programming experience to predict probable programming constructs controlling the system behavior. As seen above, Sang's explanation of the "motherboard" connecting the lights, "sound box," and the buttons in the toy bird clarified the connections between microcontroller-like processing, input, and output devices and supported his further functional and behavioral explanations (see Fig. 3, right). He connected the sensor-based interactive functionality to programming constructs by including *if-else* statements to explain conditional outcomes.

Similar to Sang, most of his peers elicited their explanations from their recent and yet limited Scratch programming experience: pointing to *if-else*, *delay*, and *forever* blocks while explaining the underlying behavior. For example, Asa employed these constructs to explain how stoplights work. "You do make a loop where certain things happen then certain activities occur… someone presses the button on the crosswalk, the green light will go a little bit faster," she said describing the loop and conditional constructs mediating interactions between human users and stoplights. Others identified the *forever* loop block in Scratch (e.g., Jade), the *delay* block to count down time for the lights (e.g., Leah), or the *if-else* conditional blocks to manage the input signals and affect outputs appropriately (e.g., Sunil). Though these students' descriptions were relatively advanced compared to their peers, they were limited too in further elaborating on the data and control flow between the computational unit, inputs, and outputs to account for the overall system behavior. In sum, students' initial articulation of different aspects of PCS promises its potential integration with computing teaching while pointing at pedagogical designs to meet where students are to relate computation to everyday PCS.

Discussion

Contexts such as stoplights have a potential to draw from students' user experience. At a functional level, they allow students to make connections to microprocessor-based learning systems such as Arduino construction kits. However, these user-facing PCS intentionally black-box complex underlying connections and this stands in the way of effective utilization of these systems for educational purposes. One way to get around this is to explore the affordances of student-generated drawings in revealing certain underlying aspects. As noted above, student drawings were effective in surfacing structural understanding and mediating functional and behavioral explanations when combined with the "what" and the "how" questions. Teachers can adopt similar practices to highlight the invisible processing unit and the interconnections and facilitate discussions about systems' function and behavior. To surface the invisible program execution that controls the system behavior, teachers can employ notional machines i.e., pedagogical devices to communicate program execution (Sorva, 2013) and be informed by students' prior programming experiences (e.g., Scratch in the examples above). Future research can explore learning activities to integrate everyday PCS with computing education. To conclude, future research, as well as careful pedagogical design can make room for everyday PCS within computing education.

Characterizing Student Theory Building in Computational Modeling

Hillary Swanson, Utah State University, hillary.swanson@usu.edu
Bruce Sherin, Northwestern University, bsherin@northwestern.edu
Uri Wilensky, Northwestern University, uri@northwestern.edu

Abstract: It is widely agreed that engaging students in authentic science practices is important for science education. Theory building is a central practice of science. Today, many scientists build theory through computational modeling. This paper characterizes the nature of student theory building in the context of computational modeling activities. Using a fine-grained grounded analysis, we identified theory-building moves in one student's goal-directed modeling in a block-based microworld. We present moves enacted during phases of model building, testing, debugging, and sense-making using a segment of transcript from the student's theory-building activity, which was focused on modeling a flu epidemic.

Introduction

It is widely agreed that engaging students in authentic science practices is important for science education (Duschl, Schweingruber, & Shouse, 2007). Theory building is a central practice of science. Many scientists build theory by constructing computational models that, when run, produce outcomes that can be explored and compared with experimental findings (Foster, 2006). A number of research programs have explored ways of engaging students in theory building through computational modeling. diSessa (1995) describes a case where high school students re-invented F=ma through their development of computational models. Wilensky and colleagues have investigated student construction of models of complex systems phenomena such as predator-prey dynamics, using the NetLogo computational modeling environment (Wilensky, 1999; Wilensky & Reisman, 2006). Recent work in this tradition has examined student construction of models using NetTango Web (Horn, Baker & Wilensky, 2020), a block-based interface to NetLogo. The present work builds on this tradition by examining the nature of student theory building in the context of computational modeling activities. It seeks to characterize elements of theory building supported by block-based microworlds.

Theoretical foundations

We define scientific theory building as a family of practices through which scientists and students systematically refine theoretical knowledge artifacts, including laws, models, explanations, constructs, and categories (Swanson, 2019). As these artifacts are refined, thinking is refined. Our perspective aligns with constructivist frameworks that view the construction of new knowledge as a refinement of prior knowledge (diSessa, 1993). It also aligns with constructionism (Papert, 1980), which argues that learning happens best through the construction of public artifacts, such as computational models. In our work, we seek to characterize students' theory building by describing the moves through which they refine their computational models. These are moves through which their ideas are systematized and formalized, and brought into alignment with evidence and observation. We are focused on identifying these moves for two reasons. First, we view them as productive resources that can be leveraged and developed by instruction toward expertise in theory building. Second, we are interested in mapping a gradient from less to more expert theory building, and in so doing, locating student theory building on a continuum with the theory building of scientists. In this paper, we focus specifically on characterizing the *process* of student theory building, leaving the science *learning* that results to other papers.

Methods

We present results from an analysis of data taken from a larger study focused on supporting middle school student engagement in different approaches to scientific theory building, including the construction of computational agent-based models. To make computational agent-based modeling more accessible, we are designing block-based microworlds using the NetTango interface to NetLogo. NetTango makes the computational power of NetLogo accessible to authors by using a block-based programming language curated to a particular phenomenon. NetTango blocks are not a full programming language, but domain-specific blocks relevant to the modeled phenomenon. Previously called *semantic blocks (*Wilkerson-Jerde & Wilensky, 2010) and now called *domain blocks* (Wagh et al., 2017) the blocks are, from a student's point of view, primitive elements of code that represent agents' actions, which can be combined to model a specific phenomenon. We are designing domain-block libraries for simulating complex systems phenomena and studying how children use the blocks to engage in scientific theory building. In this study, we ask the question *"What is the character of student theory building in the context of computational modeling?"*

To address this question, we tested NetTango modeling microworlds with middle school students (ages 12-14) during one-on-one 1.5-hour task-based interviews. During each interview, the student had full command of a laptop featuring an agent-based microworld. The interviewer guided them through tasks and questions from a semi-structured protocol, which introduced the features of the microworld and then prompted the student to model a particular phenomenon. This study focuses on an interview with Sage, a 13-year-old who had just started 8th grade at a public school in her small Midwestern city. Sage explored the *Spread of Disease* model, shown in Figure 1, below. Figure 1 shows the microworld with a model of Ebola built by Sage. The black box to the left is the *world* which depicts the activity of the agents that are programmed to behave according to the rules specified by the model. The *setup* and *go* buttons are controlled by procedures (red blocks) that the user must drag from the block library (far right) into the modeling field (middle) and then define by connecting with blocks (purple, grey, and green), such as *move*, *if contact person*, and *infect*.

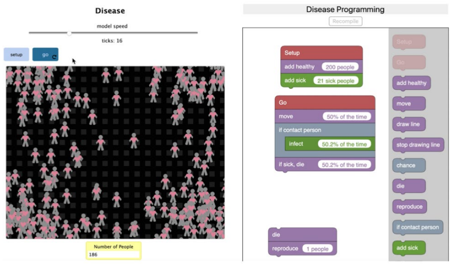

Figure 1. The *Spread of Disease* microworld featuring Sage's model of Ebola.

Sage's interview was recorded using video, audio, and screencast technology. The audio recording was transcribed. A fine-grained grounded analysis was applied to both the screencast and transcript to identify theory-building moves that Sage enacted (Glaser and Strauss, 2017). First, the screencast of Sage's interview was reviewed and times were noted during which she engaged in building models for particular diseases, namely Ebola, the flu, and a zombie apocalypse. These episodes were then marked on the transcript, which was read for evidence of theory-building moves, which were named and organized into phases of model building. These were: 1) building, 2) testing, 3) debugging, and 4) sense-making. For the purposes of illustrating the moves she enacted, the moves were used to characterize the episode of Sage's modeling in which she tried to model a flu epidemic. The episode was temporally decomposed into steps of model building, testing, debugging, and sense-making. The episode is presented in the Findings section as a piecewise trajectory. The transcript associated with each step is followed by a description of the smaller theory-building moves in which Sage engaged, highlighted in italics.

Findings

The grounded analysis of the three episodes revealed 46 theory-building moves across the four phases. We present a narrative account of a segment of Sage's modeling activity to illustrate how she engaged in building, testing, debugging, and making sense of her model. We offer a temporal decomposition of the first three minutes of the 10-minute trajectory through Sage's flu modeling activity, highlighting her theory-building moves in italics.

Modeling the spread of influenza

Sage is seated at a desk in an office, the interviewer sits at her left. She is looking at a laptop screen on which the *Disease Spread* modeling microworld is open. She has been exploring the microworld for the last 40 minutes. Her exploration began by trying out combinations of blocks and watching the resulting activity in the *world*. She then built and refined a model of Ebola (Figure 2), at the interviewer's request. Following this, the interviewer asks Sage how she would modify the code in the Ebola model, to model the flu.

Step 1: Building the initial flu model

Sage looks at the model of Ebola and considers how she might modify the code to represent the flu.

> Sage: If it was flu, hmm, it's less deadly [...] Like, I don't know, like 10%.

To match her understanding of the flu, Sage *purposefully selects a parameter value*, decreasing the probability that a sick agent will die, from 50.2% to 10%, and then to 5.5%. She appears to be *drawing on prior knowledge* she has about the difference in deadliness of the flu *as compared* with Ebola. She *approximates the parameter value* and shows an *awareness of the limits of her knowledge*, qualifying her choice with the words “I don’t know.”

Step 2. Testing the initial flu model

The interviewer asks Sage how she thinks her modification is going to influence the model outcome.

> Sage: I think the epidemic is going to spread like much further because, um, people like when people are moving around and infecting people, they're like, they're, they're not, they don't have like a 50% chance of dying every time. [...] And so people weren't, people were dying faster than they were coming in contact with people instead of-

Sage *makes a prediction for the outcome of the model run*, and *explains her prediction* by *comparing her expectation with results of previous runs* of her model of Ebola. She *explains the aggregate-level outcomes of those runs as the result of agent-level interactions*. Her reasoning is that for Ebola, “people were dying faster than they were coming in contact with people,” and the disease disappeared from the world before it could turn into an epidemic. For the flu, she reasons that the epidemic will spread because it is less deadly and therefore sick people will be in the world long enough to infect healthy people. She appears to be *drawing on knowledge* she constructed while modeling Ebola, that if the disease is deadly to infected individuals it will kill them off before they can spread it and decimate the population. Sage presses “go,” running the model to *test the effect of her new parameter* and *observing* as the model runs. She watches as the number of people in the world decreases as healthy people become infected and sick people die. This outcome stands in contrast with her Ebola model, where all of the initially sick people died in the first few ticks.

Step 3: Making sense of the initial flu model

The interviewer asks Sage if she thinks this model looks different from her model of Ebola.

> Sage: Yeah. Um, I think the percentage of population is like going down as you can see.
>
> Interviewer: Ah, so what did you change in the um, the flu case?
>
> Sage: Well, people died less and it spread less. And so, we went from like 221 people, 41 people because it's, um, it's very infectious, but it's like, like people don't die a lot. But when there are a lot of people then people start dying. [...] And so just people keep dying and then eventually [...] So, because no one's recovering, you can't, I didn't have it set to recover.

Sage tests the model and *describes its outcome*: that the population is decreasing over time. She *compares the results of this run with results of the previous runs* of the Ebola model, where fewer people died, because the sick people died before the disease could spread. She turns to the flu model-run results, *referencing numerical data* that she *calculated* by subtracting the value given in the box titled “number of people” from the total initial population (the population has decreased by 41). She *explains the aggregate-level outcome of the flu model in terms of agent-level behavior*. She explains that the flu is very infectious but less deadly to those infected. If there are a lot of people, some percentage of the population will die, so the population decreases. Through her sense-making, Sage *arrives at a powerful conclusion about complex-systems dynamics*: when a disease is less deadly to infected individuals, infected people die less and the disease spreads to more of the population. If there are enough people in the population, many people will ultimately die. Sage acknowledges that the population may have decreased too much in her model, because the only option for sick people is to eventually die, as she left out the “recover” block. Sage *connects the agent behavior with the model code* and engages in debugging, identifying this as a *problem with the model*.

Step 4: Debugging the initial flu model

The interviewer asks Sage if she thinks as many people die in a flu epidemic as shown in her model.

> Sage: Probably not. It's probably because I have the infectivity high and people aren't recovering. But let's say you recover like, I don't know, 50%? No, like 75 but that's going to be way too high. Yeah, 75 and less infectious, and this will be hard to start your... Wait, no, that's recover, wait. Yeah. Infect like 10%.

At the interviewer's prompting, Sage *assesses the reasonableness of her model's results*. She explains the unexpected *outcome at the aggregate level as the result of both an incorrect parameter setting* and *incorrect agent behavior*. She engages in debugging, *modifying the code to address the problem* by adding the "recover" block to the model and setting the probability of recovery to 73.1%. She also debugs the model by *modifying a parameter to address the problem*, reducing the probability of infection from 50% to 10.5%. Following this, Sage continues to work on her model for another 7 minutes, working through an additional 18 steps of testing, making sense of, and debugging the model. All the while her goal was to find a way to get the epidemic to sustain itself and work more like her image of the flu epidemic. Over the 10 minutes of the activity, Sage demonstrated many moves that may be productive foundations for developing expertise in areas of theory building, including model building, testing, debugging and sense-making.

Discussion

This study characterizes student theory building in the context of computational agent-based modeling. Working in the microworld with the support of the interviewer, Sage engaged in theory building by constructing, testing, debugging, and making sense of a computational model. By identifying and characterizing Sage's theory-building moves, we identified resources she brings to her learning that may serve as foundations for developing expertise in theory building. In this way, we make a contribution to literature concerned with identifying the resources novices bring to their learning that can be foundations for the development of scientific expertise. The work makes a contribution to the larger project of characterizing the nature of student engagement in different forms of scientific theory building by characterizing student engagement in computational agent-based modeling. By identifying the smaller moves of which this approach to theory building is composed, our findings are foundational for the development of science curricula and assessments that promote and capture rich student engagement in scientific theory building.

Student Perceptions in a Formal Makerspace: A Case Study of Two High School Senior Students and their Collaboration on a Computer-Aided Design Project

Sarah Lilly, University of Virginia, scl9qp@virginia.edu
Sarah Shepherd, University of Virginia, srs9kx@virginia.edu
Anne M. McAlister, University of Virginia, amm8km@virginia.edu
Jennifer L. Chiu, University of Virginia, jlc4dz@virginia.edu

Abstract: While collaboration is a major theme across makerspace studies (Papavlasopoulou et al., 2017), few studies consider how students perceive collaboration within makerspaces. This single case study explores secondary students' perceptions of their collaborative experiences while working on a computer-aided design project in a formal makerspace. Survey, observation, and interview data were collected and qualitatively coded. Findings demonstrate how a student with technical expertise can take on increasing ownership of a peer's project and limit learning opportunities for the partner student. Implications include how teachers can orchestrate and monitor collaborative relationships to support students' success and agency in formal makerspaces.

Background and significance

Many school systems are incorporating technology-enhanced learning environments as formal makerspaces (Peppler et al., 2015) to connect curriculum-based content to professional skills and engage students in communities of practice that cater to their personal interests. While collaboration is a major theme across makerspace studies (Papavlasopoulou et al., 2017), there is little consideration of the students' perceptions of collaboration or how passion-based learning may affect students' experiences within the makerspace. Our research seeks to privilege student voice by considering two secondary students' perceptions of their collaborative experiences while working on a computer-aided design (CAD) project in a formal makerspace. We consider: How do students collaborate within a formal makerspace and to what extent do students' perceptions of these collaborations affect their experiences within the makerspace?

All students should be supported in gaining the skills needed to engage in the professional communities of their interests and choice. Our findings can provide insight into student perspectives for educators toward better understanding the support that students need to actively engage in positive, collaborative learning experiences within a formal makerspace and creating equitable learning experiences for all students.

Collaboration and equity in makerspaces

Papavlasopoulou and colleagues (2017) suggest that collaboration is a major theme across makerspace studies. Prior research shows that students in makerspaces use collaboration to create relationships in which they work together for access to skills and a diversity of knowledge (e.g., Gutiérrez et al., 2014) by recognizing the skills and interests of their peers. The ability of a peer group to negotiate roles, allocate responsibilities, and build a collective product from individual work is called collaborative agency (Kafai et al., 2012). Additionally, makerspaces emphasize learning through doing where students build upon their existing resources, learn practices that are authentic to professional communities within their areas of interest, and develop their own identities through collaborative interactions (e.g., Baker & Lattuca, 2010). Thus, collaboration may be critical to helping students develop an identity as a member of a makerspace learning environment.

Formal makerspaces may offer an asset-based approach to help traditionally marginalized youth engage in passion-based learning. However, while formal makerspaces offer the opportunity for marginalized youth to engage in passion-based learning at school, collaborations within makerspaces can also hinder equitable participation in learning. For example, a student who needs help may begin to collaborate based on helplessness or replication (Sheffield et al., 2017). Similarly, when makerspace participants feel knowledgeable, they may choose to share their knowledge or either take over the work or refuse assistance (Maltese et al., 2018). While equitable collaboration on long-term projects increases the opportunities for marginalized youth to build supportive social networks, if collaborative roles remain consistent and become part of students' identities in the makerspace then hierarchies may develop that negatively affect future collaboration (Barton et al., 2017). Collaboration can then also promote inequity (Maltese et al., 2018). Thus, more research is needed to understand how students perceive collaboration in makerspaces to increase the likelihood for equity in collaborations.

Study context

In this holistic, single case study (Yin, 2018), we consider two students (Theodore and Joseph) who worked together on a CAD project in a formal makerspace, Maker High, over a two-week period. Maker High was available for high school seniors across a public school district to attend during the second half of every other school day and receive course credit. Although there were two teachers at Maker High, a preliminary review of Theodore and Joseph's surveys showed that their passion-based interests of using computers to create designs were outside of the teachers' range of expertise. Further, Theodore's survey included his plan to begin work on a CAD project that involved technology that he had never before used but that Joseph had promised to help him learn. The opportunity to focus on a student who may not have been able to seek help from a teacher but was seeking a collaborative relationship with a peer led to our decision to study Theodore and Joseph.

Methods

Over the course of two weeks in the spring, the two students were observed working on the design portion of their CAD project for four days, for four hours each day. Audio recordings of the students' discussions were collected and transcribed and the observing researcher wrote daily analytic notes in a reflexive journal. Immediately prior to and following each observation, semi-structured interviews were conducted with the students to understand their goals, challenges and successes, and perceptions of collaboration while working on the project that day. Data from surveys conducted at the beginning of the school year, mid-year, and at year-end, asking students questions regarding prior collaborative experiences in non-traditional learning environments and their current collaborative experiences at Maker High, were included in the analysis to increase construct validity using data triangulation (Yin, 2018). Two researchers coded 20% of the data from all of the sources with first-level codes in 5% increments, discussing and reconciling any disagreement after each set of 5% increments to obtain an inter-rater reliability above 80% (Miles et al., 2020). These codes included descriptive coding to summarize when students discuss different settings in which they have experienced collaboration and their perceived success and challenges of collaboration; concept coding, using a symbolic word or phrase that suggests an idea; and emotion coding, when participants recall emotions, to consider when and how students perceive emotional support. The researchers then divided and coded the remaining data separately, discussing any uncertainty. The researchers separately engaged in a second-level method of pattern coding to categorize potential themes and compared their analyses to reach consensus.

Results

Theodore and Joseph's collaborative roles

Joseph's prior experiences in four different CAD courses at his base school led him to have an expertise that no one else at Maker High (including the teachers) had. Theodore approached Joseph for help prior to beginning his project because he was aware of Joseph's expertise. For Theodore, this was an affordance of attending Maker High: "I have plenty of ideas but I have no idea how to do them and [Maker High] helps make my ideas happen." Through the two weeks spent working on the CAD design, Joseph took on a mentoring role that surpassed occasional help. As Theodore had questions, Joseph would leave his nearby computer station to provide help. By the second observation, Joseph had made the choice to abandon his project to sit by Theodore for the remainder of our observation period. He began to step into the role of a more constant mentor for Theodore. For example, he said "Theodore got past a mental barrier of not being able to get work done on it. Certain functions of CAD get annoying, but Theodore worked so hard and had a breakthrough today." Initially Joseph also focused on leading Theodore through the process of making design choices. However, as the project progressed, Joseph sometimes took the computer mouse from Theodore and edited the design himself. At times Theodore was receptive saying, "I see what you're doing. That looks good." But other times, he reminded Joseph that it was his project. For example, in the final observation, Joseph went even further in his contributions to the project by making a design change as he continued to work on the project while Theodore went to the bathroom. WhenTheodore returned, he said, "I said wait, I don't want you to do it for me."

After abandoning his own project to more closely help Theodore, Joseph began to express ownership of Theodore's project. This may have led him to begin to manage not only the project but also Theodore himself. Particularly, Joseph tried to keep Theodore on track and was concerned about his productivity. At first this involved checking in on the completion of goals without statements of judgement regarding progress. As they continued to work together, these statements became more critical. For example, as another group finished a project, Theodore suggested, "We should take a break and see what they're doing." Joseph replied, "Stop, you constantly want to take a break. You take too many breaks." These corrections then took on a more negative tone.

Joseph's perspective

Joseph's willingness to step into a helper role was surprising since, when asked at the beginning of the year who he hoped to work with during his time at Maker High, Joseph had written "a person that already has a ton of background knowledge because I'm not a fan of teaching other people something and would like to have a person I can work with, with the same sort of mindset". However by mid-year, he reported feeling that he did not have equals in terms of technical knowledge or even peers working in the same area of interest, writing, "I don't have many people doing engineering so I probably can't find someone to work with." When asked about helping Theodore manage his time and stay on task, Joseph stated that he was "looking to help to figure out what [Theodore's] next steps are because he gets sidetracked a lot which isn't always a bad thing but he needs sometimes someone to tell him what he should be doing next." Joseph's investment in the successful completion of Theodore's project went past simply finishing the CAD design. He offered to help Theodore use technology at his base school, unavailable at Theodore's, and use 3-D printers, CNC routers, and welding to build Theodore's project outside of Maker High.

Theodore's perspective

Throughout the project, Theodore seemed receptive and appreciative of Joseph's help. He believed that he needed help to stay motivated, and he stated appreciating that Joseph helped him to increase productivity. Yet, Theodore also showed a dependency on Joseph's help. This made him feel insecure in his lack of knowledge despite his recognition that he was doing this project as a way to learn more about CAD. Particularly, he felt that Joseph could be condescending and was not always willing to explain concepts. Theodore stated that Joseph is "… good at helping when he's good at helping. He won't explain what he's talking about, he'll say do it. And I want to know the reason behind it. When I ask him to explain sometimes he does, sometimes not." This was supported in observation:

Joseph:	I just made it for you
Theodore:	Yeah but you weren't explaining it.
Joseph:	Alright just ask questions if you need it.
Theodore:	I don't know what's happening.
Joseph:	Well now you do the work. Make a hole, is that what you want to do? It's your project, take control.

Other times, Joseph appeared to attempt to scaffold Theodore's understanding by asking questions. But Theodore showed signs of frustration, asking what Joseph would do next instead of thinking through the process. For example:

Joseph:	Make everything else wood, that doesn't make sense. What else could you do?
Theodore:	Do you have an idea? Are you trying to encourage me toward an idea? That could take a while.
Joseph:	First off, I think you should make this plate a little rounder. This could come down, you'll have a bolt. You're going to need washers especially with metal and wood it gives it a metal surface to attach on.

Discussion

In this study, two students formed a close collaborative relationship within their makerspace that enabled them to work on solving the problems of a project that were relevant to them (e.g., Sheffield et al., 2017). Theodore leveraged the expertise of his peer, Joseph, who became a mentor in CAD as well as a delegator of tasks and reminder of time management. We propose that collaborative roles of "helper" and "student-in-need-of-help" may be complicated in a formal makerspace. For example, in this data, the student in need of help is also the leader of a project asking a peer for help based on their valuing of that individual's expertise. As a helper, Joseph is then working for the student leader on their project, although at times it may seem that this helper student is taking on a leader role in the project by assigning tasks to Theodore. Although not necessarily a negative role, if students are always in the same collaborative role, as Theodore and Joseph seem to be within this project, then they may be missing out on opportunities to use their own expertise or receive help on their own project.

For these two students, support and collaboration during this project was limited to their partnership. Theodore was seemingly dependent on Joseph's prior experience to complete his CAD project. Although working at Maker High allowed him opportunities to engage in professional practices, his dependency and, at times, learned helplessness within the collaborative relationship may affect the development of his identity (e.g., Baker & Lattuca, 2010) as a CAD operator. Further, Joseph's perceptions of isolation due to a lack of surrounding resources throughout the school year may have led him to work with Theodore despite Joseph's statement of not wanting to be in a teaching role. Within this partnership, the students did not have support in using their collaborative agency (Kafai et al., 2012) to delegate work. Thus, without explicit structure or support, students may not be able to draw upon or develop individual expertise, which has the potential to reinforce traditional school roles and identities in formal makerspaces.

Implications and conclusions

At Maker High, there were opportunities for rich, sustained collaboration between students that fulfilled the promise of makerspaces as environments for collaborative learning (e.g., Peppler et al., 2015). Yet, despite the idea that students can find success in makerspaces if they have access to expertise and resources through collaboration (Gutiérrez et al., 2014), care needs to be taken to avoid putting undue mentoring responsibility on students. Further, the students who are helping their peers may not support the other students emotionally or mentally despite their content or technical knowledge. Collaborative relationships, as critical as they are for students' success in makerspaces, may then need to be more carefully facilitated in formal makerspaces to avoid creating too much burden for the helping student or feelings of dependency for the student receiving help. Preferably, partnerships can be formed where students support each other more equitably or students would engage in a variety of partnerships with different collaborative roles. Teachers could then help students to manage their time and learn to manage the progress of their projects. Student partnerships could be based more on the offering of expertise and learning from a peer's skills rather than being in charge of a peer's productivity. Teachers then may need support to put into place protocols and norms of collaboration to enable more equitable collaboration opportunities in formal makerspaces.

Collaborative Data Engineering: Strategies to support Macro-level Exploration of Youth Learning Ecosystems

Nichole Pinkard, Northwestern University, nichole.pinkard@northwestern.edu
Caitlin K. Martin, Northwestern University, caitlin.martin@northwestern.edu
Ugochi Jones, Jones Technical Enterprises, LLC, ugochi@jonestechnicalenterprises.com

Abstract: The time has come for the learning sciences to expand design and research methods in order to understand access and participation to learning opportunities at a macro level. Advances in technology allow networked social systems (such as out-of-school providers) to crowdsource and combine the data they collect and interpret collectively through data representations. Learning sciences can leverage networked data as a way to stress test theories based on ethnographic research with individuals or small groups and offer learning science perspectives to how we understand and address power-related infrastructure and historic racism. In this paper, we share a process for designing technical systems, refining data models, visualizing learning landscapes, and working with decision makers to impact change using an investigation of the 2019 Chicago summer learning landscape as a case example.

Keywords: learning ecosystems, out-of-school time, data engineering, equity

Introduction

The learning sciences practice of weaving design, cognition, and context together to investigate learning has birthed new ways of understanding how people learn and how environments influence what happens. Research and design efforts most frequently use person-centered units of analysis, including what we describe as micro- (individual, family) and meso- (e.g., program, classroom, affinity group) levels. Studies have generated powerful frameworks and models of learning ecosystems with youth at the center. These egocentric models show how youth learn across places and time, illustrating how social networks and events are critical development and identity shapers and identifying potential barriers and sparks that can influence participation and persistence (e.g., Barron, 2006; Ito et al., 2013). These models have advanced understanding of how youth learn out of school, and the interconnected relationships between home, virtual spaces, school, and other learning environments. For over a decade, our own design-based research has been grounded in these egocentric learning frameworks, meaning we spent many years at the meso level of classroom and program design and study. But there are limitations to designs based on understandings that hinge on small-scale studies of specific programs or organizations or synthesis of individual ethnographies (Hect & Crowley, 2019). In the past few years, we have expanded our research beyond individual programs intended to bolster youth and family participation in computational making to consider inequities in STEAM opportunities across geographic landscapes at a macro level (e.g., cities and communities) (Pinkard, 2019). There is a lack of attention in the field to this level of study and design and as such, research to understand neighborhood or city patterns of informal learning are rare or non-existent. Addressing this vacuum is urgent in order for American communities to establish equitable learning systems informed by a shared awareness of the historic systematic racism embedded in the placement and practice of civic learning, leisure, and performance institutions (i.e., schools, parks, libraries, museums, community-based organizations). Current tools and organizational connections make this work possible (Akiva, Delale-O'Connor, & Pittman, 2020).

In this paper, we illustrate how we are engaging in research and design at a macro level. We describe a process for operationalizing landscapes at a citywide level, a direct expansion of our earlier methodology to understand learning across formal and informal spaces at smaller scales. We ask questions about distribution of opportunities at a macro level to reveal issues of access related to: places (where are the locations where learning happens?), people (who designs and offers youth programming?), and opportunity (what programs and events are available for youth to participate in?). We also share how stakeholders have been engaged in data collection and interpretation to translate understanding macro-level data to actionable design intended to (re)allocate resources for more equitable distribution and youth participation.

Building blocks from micro-level analysis

We consider our earlier methods to be the building blocks for our current work. To understand interest and development over time for middle school students participating in a series of after school digital arts opportunities, individual learning timelines were developed that linked events across time (y-axis) and environment (x-axis) and social network connections (Barron, Gomez, Pinkard, & Martin, 2014). Researchers and practitioners used understandings about key events (such as interest-driven projects, parent collaboration, and showcase opportunities) and challenges (such as limited opportunities for advancement, competing interests, perceived identities or stereotypes, transportation, or costs) to design programs and opportunities to better serve youth learning trajectories, with special attention to equitable engagement. These types of micro-level representations of unique learners and their pathways over time and across places can help to conceptualize the importance and interconnectedness of key events in youth learning and development, and how they fit into different spatial (school, home, community, and online), social (parents, mentors, teachers, and peers), and temporal (grades, ages) dimensions. Representations can be shared with practitioners and youth and families, yielding new insights and ideas for design, but are often time consuming and crafted individually based on qualitative data. In the remainder of this paper, we reveal how we utilized these micro-level building blocks about where, who, and what is going on in the lives of young people that influenced their learning journeys over time to investigate similar questions at a larger scale, utilizing current powerful technologies and analytical strategies while staying grounded in person-focused understanding about learning and development.

Methods

Given the lack of methodology for citywide understanding of youth learning ecosystems, including opportunities and participation, the methods utilized in this work emerged from a collaborative data engineering design process, including the design and implementation of a sociotechnical data collection system, and corresponding processes of input, collection, and interpretation.

Developing a platform for collaborative input about OST opportunities

Agreement that out-of-school time (OST) learning is important is common but understanding what opportunities are available, accessible, and at the right level, especially in science, engineering, and computational disciplines, often remains a black box. This lack of visibility confronts multiple stakeholders, including youth, parents, organizations who offer programs, and city and community leaders who want to ensure equitable opportunities across the geographic areas they serve. In 2013 a multi-year collaboration was established between researchers, practitioners, and city leadership, with support from philanthropic funding, to address this issue. Our team developed a technical platform and invited OST providers to input their program information and key metadata as well as youth participation data. Providers can upload a batch of programs through a .csv file with required fields (common for larger agencies and organizations) or manually enter each program. Fields captured for each program have evolved over time, prioritized by those that are (a) important for families who want to participate, (b) feasible for practitioners to easily access and report, and (c) allowing inquiry in terms of access and equity, connected to our micro-level building blocks used to explore the individual-level learning events over time.

The dataset shared in this paper included programs for youth (ages 0-18) available during the summer of 2019, including 5,583 unique program records contributed by 166 Chicago youth-serving organizations.

Constructing data models from theoretical models

A first phase in the macro-level analysis is cleaning and transforming the provider-entered data into formats that are easy to manipulate and represent the networked connections (e.g., social groups, participation trajectories, content and activity relationships) and metrics that we have identified as important from our explorations of youth ecosystems and from related research. Examples include the number of locations that youth have access to that offer informal learning opportunities (related to youth connection with physical community spaces, each with cultural and place-based resources and facilities (e.g., Barron et al., 2014)), the number of organizations or agencies who offer those programs (related to connections with various types of organizational and adult mentorship, expertise, and human capital (e.g. Ching et al., 2015)), the breadth and depth of learning opportunities in different content areas (related to engagement and interest development and deepening (e.g., Ito, et al., 2013)), and proportions of opportunities with additional supports (related to participation equity (e.g., Pinkard, 2019)).

Because ecosystems evolve over space and time, the information that we collect needs to be stored in a manner that represents our theoretical perspective, maintains longitudinal coherency, and is flexible enough to facilitate a variety of analytical approaches. To achieve this goal, we implemented a data warehousing initiative. In the field of computer science, data warehousing refers to the computing architecture used to store analytical data and the way to design data models to support analytical processes (e.g., dimensional modeling, data marts, data vaults). Going into the specifics of these technologies are beyond the scope of this paper, but we do want to identify the design approach we have taken to create an effective data warehousing initiative. Our collaborative design process as a team of researchers, designers, and data scientists is as follows: (1) *articulate and synthesize* *theoretical goals* by generating and documenting new and existing research questions, (2) *information linking* to develop metric naming protocols, information relationships, and the interpretation of metrics, (3) *ideation & feedback* as prototype data models (including relational diagrams and sample data worksheets) are presented for testing and feedback, (4) *implementation* of selected data models in the data warehouse (e.g. AWS Redshift), and (5) *access* allowing researchers to pull data into visualization tools to construct publicly shareable representations.

Connecting and visualizing data for stakeholder interpretation

Our interpretive level for this work is the city of Chicago, while the analytical level is the community boundary. Chicago's 77 community areas have clearly defined borders that do not overlap and that are recognized by the people who live within them (unlike other Chicago geographic regions, like neighborhoods, that are less defined and open to individual interpretation). Summaries of the platform data are tabulated by community area to reveal dimensions of the learning ecosystem. We consider these to be macro-level representations of the individual learning ecosystems of the youth in these geographic areas. ArcGIS is used to develop static maps and online apps that allow presentation and exploration with stakeholder groups during citywide meetings hosted by the mayor's office and smaller community meetings organized by local community organizations (Erete et al., 2020). Importantly, these maps are automated and can draw from live data, allowing comparisons of different time periods. Maps are integrated with other data sources, such as city crime data and census data, as well as youth-collected data from organizational partners classifying the types of providers surveying features of unique learning hubs (e.g., asset maps of makerspaces, instructional kitchens, recording studios, and places to hang out).

Findings

In this section we show examples of the kinds of visualizations that help to reveal distribution of opportunities at a macro level, how this illustrates both richness and gaps in opportunities across Chicago communities, and how these visualizations can be utilized to promote deeper conversations about resources, design, and interpretation.

Learning hubs and human capital

Physical spaces where informal learning opportunities are offered are not necessarily the location where agencies or providers who offer those programs are located. For instance, the location of a science museum is different from the school location where that museum offers after school programs. This type of outreach programming is relatively common, but organizations infrequently have ways to look at the holistic distribution of where opportunities are offered in ways that can support understanding of learning landscapes and providing access to opportunities where they are needed. During the summer of 2019, our dataset revealed all but two of Chicago's 77 community areas included locations that offered programs. However, there was variability between communities. Communities with the highest abundance of locations were clustered around the vertical middle of the city (figure 1a). Stakeholders noted this was possibly due to the city's public transportation system and driving infrastructure which make it notoriously difficult to move east to west and to cross the vertical midline, separating the north and south sides. Similar maps with comparative abundance of providers were created to engage stakeholders in conversations about the human capital related to OST within and flowing into community areas. Maps, importantly, encourage stakeholders to take not just a deficit perspective on historically marginalized communities, but an asset model that sees richness of opportunity and assets using these alternative indicators.

Availability of opportunities

Looking at program content areas can help reveal yet another measure of learning landscapes, yielding portraits of communities who may have valuable knowledge or depth of experiences in particular areas. It can also drive conversations about what is offered in reality compared to what is desired, including how it matches youth interests and community perceptions about what their youth need in informal learning spaces outside of school time. Figures 1b & 1c show counts of programs in two different content areas by community. While both are present in community areas distributed throughout the city, the concentration of distribution looks different.

Coverage is related to historical infrastructure and intentional funding strategies, recognized by stakeholders who act as interpreters. One example is the equitable distribution of Chicago's parks, and physical infrastructure stemming from community-driven legislation for regional parks commissions in the late 1800s. Today the distribution and abundance of sports is tightly connected to the system (in our data, park sites accounted for 97% of sports programming reaching 75 communities). Another example is the distribution of computational opportunities. Although depth of coding opportunities is significantly less than sports, the breadth of communities in which computational opportunities are offered is tied to library infrastructure and research-practice partnerships formed and funded in the past few years to create a community of practice around coding in libraries. In our data sample, 45% of the programs classified as *coding* were located in public libraries, a significant change from earlier analysis when these opportunities were tied to universities clustered downtown (Pinkard et al., 2016). These visible infrastructure patterns and changes over time show how changes in policy and collaborative interventions directly impact learning landscapes and how successes and opportunities can be made visible to stakeholders.

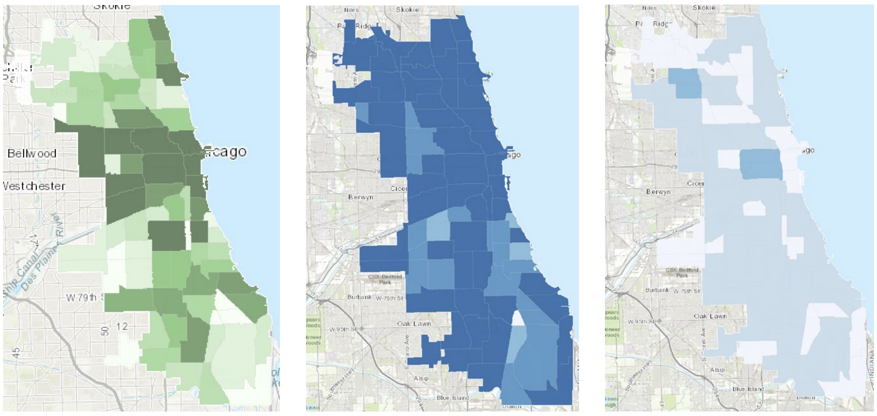

Figure 1. (a) Counts of unique *learning hubs*, and *density of programs* in the content areas of: (b) Sports and (c) coding and computational thinking (for all three maps, darker colors indicate higher counts)

Discussion and invitation

In this paper, we articulate the need for more approaches and frameworks to look at learning ecosystems at a macro level and share our collaborative multi-year effort to work at this scale. Our development of a citywide data system around OST opportunities and collaboration with stakeholders in the data collection (e.g., providers entering program data and metadata) and interpretation (through citywide and community meetings) is supporting conversations toward actionable design to (re)allocate resources for more equitable distribution and youth participation. Stakeholders can interpret patterns to consider where to offer (providers), invite (community leaders), study (researchers), or fund (city and philanthropic organizations) programming. We invite the community to utilize our platform, frameworks, and methods to support OST providers and decision-makers interested in reimaging their community's opportunity landscape. We consider this to be an ideal time for the learning sciences to expand the scope of study to a macro level in support of building a more just society.

From "Uh oh" to "I'm Curious If": Changes in Teachers' Stance over Time

Sarah Larison, Miriam Sherin
slarison@u.northwestern.edu, msherin@northwestern.edu
Northwestern University

Abstract: If teachers are to adapt lessons based on students' ideas, they must first make sense of students' ideas. In fact, a range of research has shown the importance of teachers taking an interpretive stance when discussing students' thinking in order to position teachers to promote opportunities for students' learning. Here we look at the extent to which teachers developed an interpretive stance toward students' mathematical ideas when tagging moments of classroom video in an online system. We also examine key characteristics of teachers' interpretive tags and shifts in the frequency in which these characteristics appeared in teachers' interpretive tags over time.

Background

Effective teaching requires close attention to students' ideas in order to make in-the-moment decisions that are responsive to students' strengths and needs (Richards et al., 2020). A range of research suggests that the development of teachers' ability to notice can help teachers effectively navigate this challenge during instruction (Sherin et al., 2011). Furthermore, video-based professional development has been successful in supporting teachers in learning to notice (Erickson, 2011; Sherin, 2007). In previous work, we found that a video annotation tool, what we refer to as the "tagging tool," supported teachers in attending to students' mathematical thinking while engaging with video artifacts (Larison, et al., 2019). In particular, teachers became more attuned to students' thinking over time while using the tool. Here, we expand that work by exploring changes in *how* teachers made sense of students' mathematical thinking as they noticed their thinking more routinely over time.

Examining how teachers notice has contributed nuanced understandings of teacher thinking and learning. When teachers notice they use varied lenses that influence how they interpret what they observe (Sherin & Russ, 2014). For example, when teachers notice students' thinking, they may do so from a deficit-orientation, searching for how to fix mistakes or fill "gaps," while overlooking strengths and logic in students' ideas (Jilk, 2016). Similarly, teachers tend to notice complete and coherent thinking and have more difficulty noticing students' thinking-in-progress (Diamond et al., 2018). Recent studies have shown that wider-held deficit ideologies along the lines of race and gender can also mediate teachers' noticing (Adiredja, 2019; Louie, 2018; Shah et al., 2020). These studies suggest that it may be particularly difficult for teachers to notice rich and varied types of student thinking, especially those that do not align with their expectations or that are in tension with their implicit biases. Both what teachers notice and how they notice set the stage for how they respond, and whether and how opportunities for learning are opened for students.

One approach to examining how teachers analyze classroom interactions involves characterizing the stance teachers apply in this context. By stance we refer specifically to whether teachers *describe*, *evaluate*, or *interpret* what they notice (van Es & Sherin, 2008). If we believe that students' thinking is the foundation from which teachers should adapt lessons, then we must better understand how teachers make sense of students' varied ways of thinking. For instance, we can examine how teachers seek to understand students' thinking that is not yet clear to them, or that perhaps that challenges what they expect to see and hear. Of particular importance is the assumption that when teachers seek to interpret, rather than evaluate or describe what they see and hear, they are actively working to make sense of what might not be initially obvious to them. In this study, we explore the stance teachers take specifically in discussing elementary students' mathematical thinking in classroom videos and ask three interrelated questions, (a) When using a tagging tool to mark moments of students' thinking in video, how did teachers' stance change over time? (b) What were characteristics of teachers' interpretive tags? And (c) How did teachers' interpretive tags shift over time?

Methods

The data from which we draw come from a six-week online professional development course adapted from Lomax and colleagues (2017). One goal of the course was to support teachers in strengthening their skills in noticing student mathematical thinking when watching and reflecting on their own and their peers' videos of instruction. Ten K-2 teachers from a suburban Midwestern school district participated in the course. Each week, teachers were asked to try a practice or routine designed to engage students in mathematical argumentation, video-record their lesson, and trim and upload a clip of their video to the platform to share with peers. Here we investigate teachers' use of the tagging tool to engage with videos.

Teachers were prompted to notice and mark interesting moments of students' mathematical thinking in their own and one another's videos using a tagging tool. The tool was integrated with the video itself, and teachers could press a button to pause the video at any moment. Doing so would pause the video and open a text box indicating the moment at which the video was paused, allowing teachers to make a note, or "tag," and then resume the video.

To analyze contributions teachers made using the tagging tool, we first segmented tags into idea units (Jacobs & Morita, 2002) which were then coded along the dimensions of actor, topic, and video-based. Each tag unit in which actor was coded as *student*, topic was coded as *mathematics*, and video-based was coded as *yes* were further defined as SMTV (students' mathematical thinking related to the video) tag units and serve as our variable of interest (n= 200). Next we coded the stance of all SMTV tag units as either describe, evaluate, or interpret. We characterize a tag unit with an interpretive stance as one in which the teacher sought to make an inference or hypothesis about what she observed in the video (van Es & Sherin, 2008), or explicitly surfaced a question or confusion. We believe that the latter part of our definition is important to capture how teachers grapple with the moments that are in tension with or different from their expectations. Of the 200 total SMTV tag units, 84 were coded as interpretive.

Finally, we used a bottom-up approach to coding (Miles et al., 2014) and a constant comparison method (Glaser & Strauss, 1967) to identify characteristics of teachers' interpretive tag units that were not captured by the interpretive stance code alone. In particular, we examined the ways in which teachers engaged with students' thinking as they attempted to make sense of what they noticed. This resulted in the identification of four approaches to interpreting students' mathematical thinking. The 84 interpretive SMTV tags were then coded along these four approaches, with 5 tags coded as "other." We also examined teachers' use of the four approaches over time.

Findings

We found that over time the teachers generally enacted a more interpretive stance when noticing students' mathematical thinking in videos (see Figure 1). In week 1 of the course, only 14% (3/22) of teachers' SMTV tag units took an interpretive stance. In week 2, interpretive tag units accounted for 31% (12/39) of SMTV tags. By week 3, 51% (34/67) of SMTV tag units were coded interpretive. The proportion of interpretive SMTV tag units decreased slightly in week 4, to 47% (34/72), yet remained significantly higher than in weeks 1 and 2 of the course.

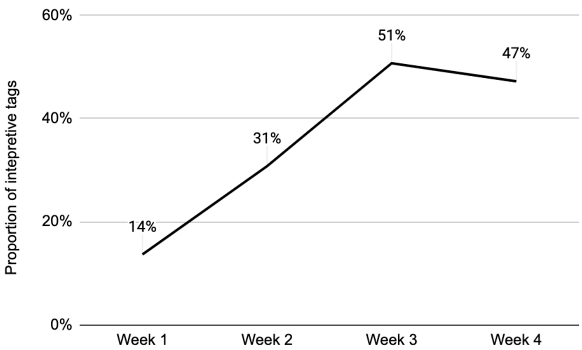

Figure 1. Percent of SMTV tag units coded as interpretive stance over time

Analysis of the nature of teachers' interpretive tag units resulted in the identification of four characteristics: fascination, curiosity, imagination, and hesitancy (see Table 1). Interpretive tag units that involved fascination were specific about what aspect of students' thinking was interesting or included inferences about why students knew, said, or did something. For instance, in a video of students solving "2 + 3 = __ + 1," a teacher tagged, "Here she is trying to rearrange the equation. She thinks that the equal sign should go after the 2 + 3 + 1. That's how she is getting to box being 6." Here, the teacher suggested that the student thought the blank space equaled six because she was trying to add 2, 3, and 1, rather than solve to make both sides equal.

When teachers' interpretive tag units were characterized as curious, they indicated that students' thinking challenged their own thinking or expectations, or surfaced an unresolved or rhetorical wondering. For instance, a teacher tagged, "I was mad the video ended... I'm curious if she then understood why 6 was not the correct answer." This tag makes clear that the teacher was unsatisfied by what she saw in the video and wanted to know more about the situation and what became of the student's thinking. Often tags that display teachers' curiosity explicitly included phrases like "I'm curious…" and "I wonder…" Further, teachers often made explicit when the things students knew, said, or did that did not align with what they were expecting.

Sometimes teachers' interpretive tag units were characterized as imaginative. In these cases, teachers considered moments prior to the video that were not visible, or a possible future moment(s). For example, a teacher noticed, "He recognizes that both sides of the equal sign have to be 'the same numbers,'" then subsequently imagined, "I wonder what they would think if they were given the equations with letters." Here, the teacher drew from what happened in the video to think about a specific, imagined future.

Finally, we found that a portion of teachers' interpretive tags were hesitant in nature. That is, teachers conveyed their understanding of students' thinking in tentative ways. For instance, a teacher tagged, "I had to re-watch this several times to understand why she put a one in the box. I think she was trying to express that the expression is counting on toward 7." The teacher explicitly notes that she was unsure of what was going on and therefore re-watched the video. Seemingly still unsure, she notes "I think she was trying to express…" as she interprets the students' thinking. A single interpretive tag could be coded as relating to more than one of these aspects.

Table 1: Characteristics of teachers' interpretive tags.

	Definition	**Examples**
Fascinated	Teachers focused on what they found interesting about student thinking or their inferences about why students thought what they did.	I was really intrigued by her thinking here. She is confident that this is incorrect because of how the equation is backwards.
Curious	Teachers indicated that students' thinking challenged their own thinking or expectations, or surfaced an unresolved or rhetorical wondering.	This explanation was a surprise to me since we talk about doubles + 1. He obviously understands making a group of ten and then counting on. He challenged himself without me asking him to.
Imaginative	Teachers considered moments prior to the video that were not visible, or a possible future moment(s).	…It's so interesting how one student sees a cupcake and the other a hexagon. *I wonder about how that translates to the way they see other things in the real world.*
Hesitant	Teachers conveyed their understanding of student thinking in tentative ways.	I was really excited when she said it was like two equations stuck together. *I thought that maybe she was seeing the equal sign in the middle and that the two sides should equal the same thing.*

When we looked closely, we found shifts in the appearance of these features in teachers' interpretive tags over time (see Table 2). Across all four weeks, the teachers' interpretive tags reflect their fascination with students' thinking. Over time, however, they became increasingly curious, imaginative, and hesitant in interpreting students' mathematical thinking. In part, this may be due to the increased number of interpretative tags that the teachers made leading to more variety in their interpretations. Yet in addition, we think these findings suggest that as teachers more routinely interpreted students' thinking using the tagging tool, teachers also routinely engaged with students' thinking in more nuanced ways.

Table 2: Frequency of characteristics of teachers' interpretive tags over time.

	Week 1	**Week 2**	**Week 3**	**Week 4**
Total interpretive SMTV tags	**3**	**12**	**34**	**34**
Fascinated	67% (2)	58% (7)	68% (23)	59% (20)
Curious	0% (0)	0% (0)	18% (6)	29% (10)
Imaginative	0% (0)	25% (3)	9% (3)	24% (8)
Hesitant	0% (0)	8% (1)	18% (6)	18% (6)
Other	33% (1)	8% (1)	6% (2)	3% (1)

Discussion and implications

In our analyses, we noted three main findings. First, teachers' SMTV tag units became more interpretive over time. This aligns with prior work that showed that teachers can learn to interpret student thinking as they attend to students' comments and ideas via video. Furthermore, related work (Walkoe, et al., 2020) suggests that a tagging tool such as the one used here may have aided the teachers focusing on sense-making around the students' thinking in the videos. Our second finding elevates the nuance in teachers' interpretations in their SMTV tags. Teachers demonstrated four characteristics in their tags: fascination, curiosity, imagination, and hesitancy. While tags that focus on fascination with students' ideas were most common, we believe particular attention should be paid to the other approaches. In particular, tags that reveal curiosity about and hesitancy towards student thinking may reflect teachers becoming more attuned to the ways that students' thinking surprises them or raises questions for them. This sense of oneself as a teacher-learner has been shown to be a powerful mechanism for change in teacher practice. Future work will examine the nature of the videos that seem to prompt these characteristics of tags. In addition, we will explore the potential value in sharing these approaches with teachers as they use the tagging tool.

Spatial Negotiation of Graffiti Artists: Pedagogical Actions in the Interest of Publicness

Beaumie Kim, University of Calgary, beaumie.kim@ucalgary.ca
Wing Ho, Independent Researcher/Artist, fhwing@yahoo.com

Abstract: This paper examines pedagogical actions and events practices by graffiti artists in different parts of the world. We examined their work through the lens of public pedagogy and based the literature on street art and graffiti, in terms of how their pedagogical actions are always forming and evolving, demonstrating how public spaces could look and be experienced differently. We examined five graffiti artists' work using the digital records of their work and online interviews. We argue through the examples of graffiti artists' practices that our design of learning environments should work toward learners' becoming public that embodies notions of plurality and difference.

Introduction

Learning sciences scholars have been advancing knowledge about how people learn and how we design learning environments in formal and informal contexts. Most recently, numerous efforts were made to critically examine and address equity and justice in public education, and the learning sciences scholars continue to find what has been relatively neglected in our field (Erickson, 2021), including our space, publics, and civic engagement. In this paper, we propose to bring public pedagogy, which concerns "the public quality of human togetherness" and "actors and events becoming public" (Biesta, 2012, p. 693), into the conversations in the learning sciences by examining the work of graffiti and street artists. Public pedagogy is about emergent forming and evolving of the public sphere, sustaining plurality and difference of human experience and interpretations (Biesta, 2012; Schuermans et al., 2012). Art on the public spaces could specifically open up "new ways of seeing, feeling, experiencing, and describing the world" (Schuermans et al., 2012, p. 677). The arts in formal learning spaces have often been a subject of token integration for gaining learners' interest toward other disciplines, especially STEM (Science, Technology, Engineering, Mathematics) (Kim et al., 2019). In this paper, we hope to show how pedagogical actions and events could look like when we demonstrate concern for publicness.

Graffiti art and public pedagogy

Graffiti and street art can be considered a "tacitly sanctioned" expressive form (Pennycook, 2010) when the street art scene contributes to the narratives and life as part of the urban landscape to the eyes of the public. Some scholars and art educators made efforts to recognize and include graffiti as legitimate art form within art education (e.g., Christen, 2010; Eldridge, 2013; Pennycook, 2010; Hampton et al., 2013), to incorporate youth's and young adults' values, subcultures, and activisms as important aspects of their learning, such as hip-hop and graffiti subcultures (Gosine & Tabi, 2016). Graffiti and street artists' practices of resisting power and existing structure have the resemblance to pedagogical approaches with criticality: the practice of "a constant unveiling of reality" (Freire, 1970/2002, p. 81) through problematizing what seems natural or inevitable in our world (Giroux, 2011). In fact, graffiti and street artists create the subcultures that constantly disclose and problematize the politics of urban spaces. Biesta (2014) describes public pedagogy as the collection pedagogies in the interest of publicness, which are activist, experimental, and demonstrative. They are activist pedagogies by resisting the private sphere and creating alternative ways of being in public relationships in plurality; they are experimental pedagogies by generating numerous ways and outcomes of actions that emerge from their socio-cultural interactions; and they are demonstrative by showing the possibilities of doing things differently (Biesta, 2014; Cooper & Sandlin, 2019). In this paper, we explore how the work of contemporary graffiti and street artists demonstrates activist, experimental, and demonstrative pedagogies in the interest of publicness and how we might consider public pedagogy as part of our scholarship and practices.

The study

This paper examines the practices of five active graffiti and street artists as a phenomenological reflection (van Manen, 2003) of their lived experience. The second author led the study and started by contacting the artists through Instagram, which is the artists' popular means of sharing their work. Data was collected through written interviews to questions (e.g., What are some of the significant moments in your artistic journey?), Instagram chats and posts, and other websites. The analysis was focused on this phenomenon of the artists' claiming their presence and voice on the walls of their cities. The approach is interpretive as we reflect on their personal narratives, practices, and artifacts. We considered their shifts in practices, their use of space, and how they reconfigure and appropriate the urban space. In doing so, we uncovered how their interventions diversify, alter and destabilize the narratives of the visual urbanscape that is monopolised by establishments of authority (hegemonic values) and how their practice resembles public pedagogy. We chose artists who engaged in legal and/or illegal graffiti and practising in non-US cities for this paper. We also foreground the practices and views of female graffiti artists.

Findings: Spatial contestations and plurality of practices

The manifestation of graffiti is regarded as a sign of societal inequalities, it is indicative of contrasting perspectives of what urban space should be and its meaning is negotiated and disputed (Zieleniec, 2017). Drawing from Harvey (2001, 2007, 2012), Zieleniec (2016) argues that the neo-liberalist economic model that decides the planning of space in urban cities champions efficiency and uniformity, but suppresses diversity. Surveillance is also one of the features of the neo-liberalist approach to spatial and social control. Existing in conflict, graffiti is often positioned within the contested notion of "destruction vs creation" (Dovey et al. 2012, p.22). Young (2012) observed that in more extreme cases, this resulted in "over-criminalisation" (p.2) of graffiti artists being handed down with harsh penalties. SeronMoon, a legal female graffiti artist from Hatay, Turkey shares that: "*There are more dangerous things in the world. Terror, war, murders, hunger, migration etc. but everyone thinks our art is dangerous. It is too silly. Laws must protect poor people but it does not protect them. It protects walls only.*"

SeronMoon's views question the rationale of the laws against graffiti artists, wall ownership and the right to participate in contributing to the visual landscape of the city. Further, the visual noise generated by corporations' billboards and advertisements are produced without consulting the residents residing in the urban space (Pennycook, 2010). This exposes the extent of control that corporations have over the urban visual scape (Christensen & Thor, 2017). Law and policing can affect the act of graffiti writing. Xiang201 from Keelung, Taiwan shares his experiences that contravene the strict enforcement of laws that persecute graffiti artists: "*the police in Keelung are relatively lax in enforcing the law because they also understand the beauty of graffiti art, this is very magical. But in Taipei, it may legally limit the creative space of graffiti artists, and I think it affects the artists who want to convey the meaning… I'm very lucky. I've met the police many times but they only told me to stop or let me continue to create.*"

Figure 1. PESKO's graffiti murals.

Xiang201 prefers to work on legal walls as it affords him the time to perfect his work without the pressure to complete his work quickly. In a study by Halsey and Young (2002), city councils demonstrating leniency allowing graffiti artists to work on local walls offered a bridge for them to communicate with the local community through their artistry. PESKO from Sfax, Tunisia is a typography street artist who juxtaposes graffiti-influenced lettering with typography advises that permission is absolutely needed to paint on any walls in Tunisia. His unique lettering style (see Figure 1) is a sharp and refreshing contrast to the drape and uniform architectural landscape that dominates north African cities. It may seem that legal graffiti is constrained by strict local regulations, but PESKO's creations do not conform to the aesthetics of a typical northern African city and transform the visual landscape populated with rectangular-structured buildings. There is no critical theme in PESKO's graffiti, but we see how his benign art adds to the city's visual narrative with bold and pastel palette along with peaceful messages.

Drawing from Lefebvre, Zieleniec (2016) argued that the inhabitants of streets have the right to the city's urban space, and that graffiti and street art show "the possibility of refashioning, recreating, reclaiming the city and the urban for people and not just for profit" (p. 4). PESKO's work demonstrates to the public how the city space could look different when embracing plurality of human actions (Biesta, 2012).

In emphasizing plurality in public pedagogy, Biesta (2012) suggested "[a]s soon as we erase plurality we deprive others of their actions and their freedom, and as a result we deprive ourselves of our possibility to act, and hence of our freedom" (p.688). Working on a very broad spectrum of materials and tools, Nemo, a Barcelona-based female graffiti artist who practises both lawful and unlawful graffiti shows that one need not be bound by the parameters established by those who set it. Nemo refuses to homogenize the urban space as well as the work of graffiti art. In the interview, Nemo mentioned, "*Graffiti is total freedom…I always avoid copying. I experimented a lot even if people couldn't understand me… I'm making my own DIY tools, combining ideas and get inspired by improvisation directly in the streets.*"

She tested and developed the graffiti-form using computer and video technology to project graffiti images on the wall, called graffiti mapping. Crossing over to the non-digital realm, she invented ways to create graffiti-tags (quick rendering graffiti artist's signature on street wall) using paint rollers and flip-flops to make imprints of her graffiti name on street surfaces (see Figure 2). Graffiti-tags are often produced by using markers, and Nemo contributed new techniques to the existing graffiti forms using banal items drawn from daily life. Through her experimental actions, she re-interprets how the graffiti-tag may be executed and manifest visually.

Figure 2. Nemo's walk tagging flip-flops.

Figure 3. Ladies on Wall group's graffiti mural painting.

Bunga, a female graffiti artist from Indonesia who now paints on legal walls, must deal with the disparaging comments from the graffiti community made up of men. She recalled that, *"one day I've found that my graffiti buddies are making fun of my endeavours searching my 'identity', I've been judged that my skill sucks but I've got lots of job and opportunities from it and they thought that I don't deserve that much. It hit me hard"* (Bunga, Interview 1). Male members within her graffiti circle have the assumption that, *"females can't do better artwork than males"* (Bunga, Interview 2). Working within this male-dominant subcultural art form, women are often met with biases that discredit their capabilities (Pabon, 2017). Bunga later started, "Ladies on Wall" (LOW) group (see Figure 3) to recruit women of Muslim and Hindu backgrounds to support them for graffiti mural painting skills. Not totally free from male criticism of their creations, the emergence of this legal female graffiti crew, however, signifies the aspiration to develop a system separate from an established one monopolized by men. Further, it acts as a competing voice that seeks to assert a spot in the urban space where women express themselves in solidarity. LOW group's street artwork shows their actions of becoming public (Biesta, 2012), practicing activist and demonstrative pedagogies of encouraging young women with artistic talent to express themselves and showing others in public new possibilities of being as religious women.

Discussion and conclusions

As urban spatial expressions, legal and illegal graffiti reflect multifaceted perspectives and practices as demonstrated by the graffiti and street artists in our paper. Working in different contexts, the artists navigated a complex terrain, most of them pushing boundaries implicitly or explicitly, contesting the obstacles that are constructed to subdue their voices. For instance, SeronMoon resisted and disputed the grounds of the law that persecutes graffiti artists who pursue to decorate city surfaces. Introducing new visual elements to the Tunisian cityscapes, PESKO paints graphic and calligraphic letterings on surfaces that clash and invigorate the space. Challenging the practice of graffiti, Nemo implemented new ideas using mundane objects like flip-flop sandals as a tool to execute graffiti tags. Operating in a patriarchal environment, Bunga led a collective effort for women artists to occupy the walls with their graffiti murals. Working in exceptional circumstances where authorities demonstrated leniency towards graffiti, Xiang201 experiences freedom to express and hone his craft to communicate with the public. These examples of graffiti artists' practices evince a world depicted by Biesta (2014) that centers on public pedagogy and plurality that serves the community, providing experimental, activist and demonstrative approaches to spatial and visual politics. The artists introduced in this paper might be practicing the same art form, sometimes prohibited and other times sanctioned. On the other hand, each of them engages in spatial negotiation differently within their own sociopolitical situations. In the interest of publicness, their pedagogical actions are deeply ingrained within their communities, while considering and challenging the existing power structures, hegemonic values, and dominant practices. We suggest that bringing public pedagogy into the conversations in the learning sciences is an important step in exploring how we might centralize publicness in our scholarship and practices.

Scientific Modeling Practices Through Perspective Taking in a Mixed Reality Embodied Learning Environment

Morgan Vickery, Joshua Danish, Xintian Tu, Mengxi Zhou
moravick@iu.edu, jdanish@indiana.edu, tuxi@iu.edu, mz13@iu.edu
Indiana University - Bloomington

Abstract: We present a study for first grade students engaging in Science through Technology Enhanced Play (STEP) – a mixed reality embodied learning environment which tracks student movements as they act as honeybees collecting nectar. We attend to how students take up first and third-person perspectives as they work to communicate the location of flowers to their peers through the design of a "waggle dance" and collaboratively make sense of agent behavior in complex systems through embodied modeling. We discuss patterns in students' perspective-taking and its intersection with iterative modeling practices and report on how facilitating these shifts allows students to be positioned as the designers and subjects of their own models while fostering the synthesis of abstract and concrete ideas.

Keywords: perspective-taking, modeling, mixed-reality, science education

Introduction

Developing scientific models is a core practice in K-12 science education. In previous research, we've explored how embodied play can serve as a tool to help young children develop these scientific models (Tu et al., 2019). However, we often see gaps and obstacles in how students conceptualize elements of their models across perspectives and contexts. For instance, we notice that students often struggle to make associations between their movements and the abstract concepts they are representing upon embodying their dances. Therefore, in this research, we use two episodes to illustrate the ways in which students embrace first and third-person perspectives within their modeling and sense-making to answer the following three research questions:

1. What does the taking up of first and third-person perspectives accomplish for students?
2. What leads students to shift between perspectives?
3. How does perspective-taking foster students' engagement in modeling practices?

Theoretical framework

We build on sociocultural theories of learning, which note the importance of social and interactional contexts for shaping and defining learning (Danish & Gresalfi, 2018). Researchers have noted that the ways individuals position themselves or are positioned within social contexts can influence how they interact, how they perceive the world around them, and what they take out of the social situation (Goodwin, 2017). In our work, we also build on theories of embodied cognition, which note the important role of the body in learning. A sociocultural approach to embodied cognition combines these two strands, noting how physical movement can simultaneously support cognition and perception, while also drawing upon and helping to reify the social context in which it occurs (Danish et al., 2020). In the present study, we are interested in how students' draw on these shifting embodied social perspectives while creating scientific models, to better understand how embodiment may support modeling in unique ways.

The present study builds on our prior work on the Science through Technology Enhanced Play (STEP) project (Danish et al., 2020). In STEP, students collaboratively develop an embodied model of a phenomena; in this case, student are modeling how bees communicate the location of flowers with nectar to other bees in the hive using a "waggle dance" as they collect nectar. Students act out how they believe bees will behave as the STEP software environment tracks their movement using computer vision. Their movement is used as input for the computer simulation and students see a honeybee avatar on a shared screen which moves virtually as they move physically.

As students embody the bees, they are engaging in the process of creating and refining models of how honeybees collect nectar. While modeling is an underutilized practice in elementary education contexts, research has demonstrated that such practices have merit for young learners' science education (Louca & Zacharia, 2015). We use Fretz et al.'s (2002) modeling practices taxonomy to conceptualize modeling as an iterative process of planning, searching, synthesizing, analyzing, explaining, and evaluating. These classifications, alongside understandings of modeling and play that define each as rule-based activities and position play as means to introduce scientific modeling to young learners (Tu et al., 2019), offer a theoretical grounding for understanding how students collectively negotiate meanings in practice and understand the underlying phenomena.

In the context of an embodied model using STEP, students coordinate their motion as part of the modeling process, shifting between roles as they move from a first-person perspective of embodying a bee, to a third-person perspective of describing how bees behave. We know that first and third-person perspectives utilize the body in distinct ways (Stec, 2012); however, it is less clear how moving between these viewpoints be conducive for model development and revision, particularly in a fully embodied context such as STEP. The present analysis aims to build on this prior literature by examining how students develop and shift between these two viewpoints while creating embodied models, and how this process supports their engagement with the underlying phenomenon being studied.

Methods

Participants

Twenty-three first grade students from a Mid-western classroom in the United States participated in an eight-session activity to learn about honeybee nectar collection from a systems perspective. Each session consisted of a 30-minute STEP activity where students explored how honeybees collect nectar by embodying the role of honeybees within the STEP environment. While students physically moved around the classroom, the STEP system tracked their motion as input into a computer simulation that was projected at the front of the room. Thus, as a student moved to the front of the room, they might see their bee avatar moving away from the hive and towards a flower, helping them explore how bees collect nectar from the flowers. All classroom activities with the simulation projected on the screen were videotaped for further video analysis.

Analysis

In this study, we attended to how shifting between first and third-person perspectives foster students' science modeling practices in the STEP environment (Danish et al., 2020). We applied Mediated Discourse Analysis (MDA, Scollon, 2001) to identify students' perspectives in video data, and to construct explanations for how these perspectives supported their modeling practices. Our team co-watched videos of students using the STEP environment while iteratively constructing and refining our account of how varying perspectives were present and what they accomplished for students. We then worked to identify key characteristics of first and third-person perspective–taking within the dataset.

While taking up a third-person perspective, students 1) used iconic gestures to communicate ideas to their peers, 2) oriented their attention towards facilitators, and 3) made small modifications to the design through a back-and-forth with facilitators or peers. This often takes the form of a cyclical questioning and revision of designs by facilitators and students. Moments of first-person perspective taking manifested as students' 1) full-embodiment of the target agents (in this case, bees), 2) attending towards one's own movements as represented on the projection, and 3) immediate modifications of designs triggered by real-time failure. Using these markers, we revisited these episodes to determine if and how these perspectives supported distinct modeling practices. We coded each group participating in the waggle dance activity using Fretz et al.'s (2002) modeling practices coding scheme in addition to isolating moments of first and third-person perspective taking using the criteria above. We present two episodes to illustrate how students shift between perspectives in response to the needs of the moment.

Findings

Question 1: What does perspective-taking accomplish for students?

Students engaged in collective, iterative design and refinement of their models. They typically started an episode with a question such as: "how do bees communicate to each other about nectar quality so that they know to visit the best flowers?" and then iterate between discussing and testing their theories.

The planning phase of the activity involves students adopting third-person perspectives as they propose an initial design that is challenged as facilitators and peers introduce new pieces of information. We see the collection and merging of new and old information into a single design as students define and articulate the core requirements and constraints. For example, when trying to understand how bees might indicate nectar quality in their "waggle dance," Abigail and her peers planned a dance that would include walking in a circle. The plan included discussion with peers, references to prior knowledge and naïve understandings, and the interweaving of novel design considerations by facilitators

Students adopted a third-person perspective while discussing how bees might behave in the model, allowing for valuable back-and-forth between students and facilitators. When ready to embody and demonstrate their ideas publicly, students shifted into a first-person perspective. This exploration allowed students to test and evaluate the efficacy of their dances while being exposed to new challenges to their design. For example, when Abigail embodied her proposed dance by walking in a large circle, and a constraint of her design became apparent to the group: the inability to use the full classroom space while one's bee must remain stationed in the simulated hive. This realization allowed for the final iteration of the dance: the replacement of the large circles with spinning in place. This design satisfied all the requirements of the waggle dance and the concerns raised by observers.

Question 2: What leads to students shifting between perspectives?

Students routinely adopted third-person perspectives early in the lesson as they planned their dances. Further analysis illustrated that students' shifts to first-person perspectives were prompted by circumstances in which teaching, clarification, testing, and/or evaluation of the design was needed. Earlier in Abigail's episode, the discovery that her design cannot be sufficiently conveyed through iconic gesture alone prompts a shift into a fully embodied first-person perspective. Abigail's design becomes a public representation of her naïve assumptions around the waggle dance and opportunities for iterative feedback.

Students frequently shift back to a third-person perspective when they acknowledge the need to debug and revise their designs based on newly realized constraints, requirements, or shortcomings of the original design. In a separate episode, Camille – a dancing student – attempted to communicate the location of the target flower to an observing student – Josie. Camille's first demonstration resulted in a failed attempt by Josie to locate the flower, prompting a revision of the dance to account for this miscalculation. Josie returned to 'the hive' and shifted into a third-person perspective to narrate and represent Camille's second performance via gestures. This second attempt was successful.

Question 3: How does perspective-taking foster students' modeling practices?

To understand students' perspective-taking within the context of scientific modeling, we coded episodes using Fretz et al.'s (2002) modeling practices coding scheme which decomposes modeling processes into *planning*, *searching* (for information), *synthesizing*, *analyzing*, *explaining*, and *evaluating* practices. As illustrated in Table 1, we see patterns in which modeling practices were present and were leveraged. Earlier in Abigail's episode, she drew upon naïve understandings of bee anatomy to develop an initial draft of the dance, defended her design to critical observers, but eventually conceding and produced a second iteration of her plan based on newly gathered information. This episode is representative of a larger pattern of perspective-taking intersecting with student engagement in scientific modeling practices; we see third-person perspectives promoting *planning*, *searching*, and *evaluating* within iterative model design.

Camille and Josie's episode exemplifies how the first-person perspective can be leveraged to instigate other scientific modeling practices – namely *analysis* and *evaluation*. Camille's first version of the dance was only revealed to be inadequate and in need of revision when Josie fails to locate the flower while embodying in a first-person perspective. This prompts Camille to reassess their dance and revise based on inconsistencies between her and Josie's interpretations of her instructions.

Table 1: summarizing affordances of perspective-taking & shifting for scientific modeling practices

	First-Person	**Third-Person**	**Cycling Between Both**
What does this perspective afford students?	Testing & Evaluation ▪ *revealing new design requirements & constraints* ▪ *making naïve understandings visible through direct action*	Explanation & Revision ▪ *defining requirements & constraints* ▪ *allowing for critical reflection and iteration*	Synthesization ▪ *bridges abstract and* ▪ *concrete concepts to develop a single design*
What produces shifts to this perspective?	Opportunities to *embody*, *demonstrate*, *teach*, *test*, and *clarify*	Opportunities to *design*, *debug*, and *revise*	

	First-Person	Third-Person	Cycling Between Both
What modeling practices are fostered?	Analyzing Evaluating	Planning Explaining Searching	Synthesizing

In these episodes, we see students engage in two sets of practices that both utilize and are prompted by the adoption of first and third-person perspectives during embodied modeling activities (see Table 1). The generation of ideas, the explanation and justification of those ideas, and the gathering of new information is made possible by students embracing third-person perspectives while first-person perspectives mediate the analysis and evaluation of those ideas. Furthermore, it is when these two perspectives are cyclically leveraged together that Fretz et al.'s (2002) sixth modeling practice, *synthesization,* is present. During this synthesis, students' theoretical solutions can merge with practical findings hereby bridging the abstract with the concrete. We argue that the sense-making embedded in this synthesization both produce and is produced by students' shifts between perspectives.

Discussion

The use of modeling practices through the lens of perspective-taking is understudied. We provide this analysis as support for the leveraging of third-person perspective during model generation and first-person perspectives during evaluation. Furthermore, by facilitating shifts between perspectives we might offer students opportunities to take on the role of designer as they draw upon observer critiques during iteration and position them as the agents within their own simulated and experimental models. The abstract and hypothetical that is negotiated amongst students during third-person generative phases of design is made concrete through direct action and immediate feedback during the first-person moments of evaluation while the frequent transitions between the two perspectives foster a synthesis of ideas and practices. Students socially negotiate understandings of agent behavior within complex systems, author models of these understandings, and experientially evaluate them firsthand.

Teacher Frameworks about Students' Capacity to Engage in Science Discussions

Ashley Bachelor, Vivian Leung, Sherice N. Clarke
abatchel@ucsd.edu, vyleung@ucsd.edu, snclarke@ucsd.edu
University of California San Diego

Abstract: How do teachers conceptualize the capacity of their students to engage in rigorous science discussions? Through a comparative case study we examine two contrasting cases that provide insight into the interpretive schemas that teachers adopt, which shape instructional practice. We use narrative analysis to examine teacher narratives around salient moments in science discussions. Our findings show that the frameworks that teachers bring to discussion shape what they notice about student contributions and thinking, their reasoning about what they notice, and how to support student learning. We use these findings to inform iterative design of personalized teacher professional development on facilitating science discussions.

Introduction

In this paper, we examine the *frameworks* (or schemata of interpretation) that undergird teachers' pedagogical reasoning about facilitating science discussions (Goffman, 1974). Teachers play a critical role in shaping *opportunities to learn* through the ways in which they orchestrate classroom discussions. How teachers use talk in the classroom shapes what counts as knowledge, marks how it is constructed and who has the right to participate in that process (Clarke, 2015).

While there's a growing body of evidence on the benefits of carefully guided subject matter discussions on student learning and conceptual development (c.f. Resnick, Asterhan & Clarke), it is rare to find this kind of pedagogy in classrooms that serve black, indigenous, people of color (BIPOC) and students from low-income backgrounds (McNeill, Pimentel & Strauss 2013). Some studies have documented the relationship between teachers' beliefs about students' capacity and their speculative reasoning and decision making around how they would orchestrate science discussion as a consequence (e.g., McNeill et al, 2013).

In the present study, we focus on teachers' memory, their recollections about facilitating science discussions, and in doing so, we excavate these memory traces to examine the ways in which teachers *code* these moments of facilitating science discussion. It is through a systematic discourse analysis of how teachers code salient moments in discussion that we seek to better understand the schemas that inform what teachers notice about facilitating discussion, and how these noticings relate to their orchestration of them. This study is situated within a longitudinal design-based research project, thus we seek to generate actionable insights that can be used to ground co-design and ongoing professional development with teachers.

Conceptual framework

We are interested in what teachers *notice* (van Es & Sherin, 2008) about practice as an indicator of their professional vision (Goodwin, 1994). More specifically, we are interested in what teachers notice as objects to make-sense of, what we refer to as *pedagogical reasoning*. Pedagogical reasoning is defined as the sensemaking processes that teachers are constantly engaged in while teaching (Shulman, 1987). This includes planning (e.g., how to uncover student thinking and foster sensemaking about concepts), facilitating (e.g., helping students to reason about each others' thinking in discussion), assessing in real time (e.g., making sense of what students currently understand based on what they say, and there their thinking may still be nascent), and reflecting with rationale (e.g., what objects seem to be mediating understanding and what you can do to further students' conceptual development). We conceptualize pedagogical reasoning as reasoning that is mediated by institutions, histories, beliefs, knowledges and experiences.

In the present study, we examine the ways in which teachers think about practice, specifically facilitating science discussions. Central to our design is the notion that teacher practice is not simply an operation on canonical knowledge and pedagogical repertoires, and learning not simply a linear pathway between PD and practice. Rather, we conceptualize teaching and teacher learning as dynamically and recursively shaped by institutions, histories, beliefs, knowledges, and experiences (Clarke & Hollingsworth, 2002). Thus, in our work to understand teacher cognition and conceptualize how we support its development through PD, we seek to trace the interconnections between the ways teachers conceptualize and enact practice.

Following Goffman, we refer to coding as the meaning ascribed to what is noticed and reasoned about (see Goffman, 1974). That is, coding is the classification schema that categorizes a student statement as "emergent thinking", a student's reasoning as "argumentation", a word as "a concept", a hand raised as "a request to participate", and a student idea as "correct". Frameworks, however, are the interpretive schemas that organize our experiences. In this sense, where pedagogical reasoning points to specific ways of reasoning that are tied to the profession of teaching, and coding points to the ascribed meaning giving to noticing and reasoning, a framework is the connective tissue that binds that reasoning--what teachers notice, the pedagogical reasoning about what is noticed, how that noticing *coded*, and then instructional decisions that derive from that noticing. Berland & Hammer note that how teachers frame practice, specifically engaging in science argumentation, informs the frameworks that students themselves take up (Berland & Hammer, 2011).

In what follows, we utilize these concepts to investigate the following questions:

(1) What are teachers' frameworks about facilitating science discussion?

(2) How do teachers' frameworks inform their a) reasoning and sensemaking about instructional decisions around facilitating discussions?

Methods

This study is situated within a longitudinal design-based research project, *ClassInSight*. The partnership is focused on secondary science teacher professional development (PD) on facilitating class discussions. Through iterative design cycles, we are co-designing a personalized app for teachers to notice and reflect on their discussion facilitation practice, and utilize these noticings and reflections to engage in deliberative goal setting around subsequent lessons.

Secondary science teachers from two school districts in Southern California are participating in the longitudinal PD study (n=22). Baseline narrative interviews were conducted with teachers prior to participating in PD to elicit their beliefs and practices around facilitating science discussions for student learning.

In this paper we report on the analysis of baseline interviews with teachers to drive our ongoing PD design work. We seek to understand the lenses through which teachers notice and reflect on how they orchestrate student thinking and conceptual development through science discussions. We posit that teachers' pedagogical reasoning and decision making are operating on and mediated by their interpretive schemas. Through examining teachers' interpretive schemas about facilitating student learning through science discussions, we can trace the perspectives that give shape to pedagogical moves, and instructional practice.

We utilized narrative analysis to examine the interpretive schemas within the narratives told in these interviews (Riessman, 2008). Structural analysis segment interviews by narrative, then constitutive narrative clauses, which capture the internal logic of a story. Through systematic segmentation, we are able to examine thematic features of the narratives within and across participants. Two raters independently coded each story for its constituent narrative clauses then discussed and resolved disagreements.

In order to elucidate the findings, we focus this paper on a detailed contrasting case of two focal teachers, *Jeff* and *Ronald*. We selected these cases as they embodied similar philosophies about dialogue for learning, but oppositional frameworks about student knowledge and their role in facilitating discussions. Thus, these contracting cases help to delineate the connective tissue between teachers' noticing, pedagogical reasoning, and decision making.

Jeff is a 15 year veteran teacher of engineering and physics at Baxter High School. Baxter HS has a population of 26.9% percent of students who qualify for free and reduced lunch and a population of 0.7% English Language Learner (ELL) students. Ronald is an 8th grade middle school science teacher at Riverdale Middle School, having taught for 5 years. Riverdale MS serves a student population, with 85.3% of students qualifying for free and reduced lunch and a population of 55% ELL students.

Findings

We present three key themes that emerged from the narrative analysis that provide insight into teachers' frameworks: their *epistemic stance* about participation in discussion, *how they conceptualized the purpose of discussion*, and their *role as a facilitator of learning* in discussion.

Epistemic stance and role in facilitating discussion

One of the themes that emerged in the narratives of Jeff and Ronald were differences in the epistemic stance they adopted with respect to students' roles in discussion. By epistemic stance, we refer to orientation that teachers adopt around what counts as knowledge in science discussions, in this sense, what teachers code as valued contributions to knowledge building in the class.

For example, in referring to which discussions were high points, Jeff shared the following:

> "...every semester we do that discussion on time travel… that gets a lot of contribution from the students. So that one is definitely a high point in terms of students throwing out, not just ideas and theories about how time works, but things that are very close to if not identical to a lot of the ones that are accepted in the scientific community or at least um, being considered in the scientific community."

In this excerpt, we see that Jeff highlights student contribution as a key component of a successful discussion. He frames these contributions as a reflection of student knowledge and attributes value to that knowledge by describing students' contributions in terms of the kind that are "accepted" or "considered" in the scientific community.

Conversely, when Jeff recalled a discussion that he coded as less successful, he expressed: "... I wanna start with what they know but that's usually near zero...". In this excerpt, we can see that the interpretive schema (or frame) that Jeff applies to students' participation interprets students participation not knowing, where in the previous except expressing ideas like a scientist is interpreted as productive. His expectations are not that students are coming up with new ideas, but rather that they are prepared to do so later in their academic career. Jeff seemed to frame discussion as the space in which students are preparing for "pushing boundaries" later in their academic career, as the place for students to share *appropriate* knowledges and establish a foundation upon which they can later engage in argumentation and the sharing of new ideas. What seems important to note here is an absence of reference to his role and agency in the process of supporting knowledge building in discussion.

Ronald, on the other hand, adopts an epistemic stance centers students' agency and voice:

> "And I wanted to make sure that we were practicing some sort of science skill ... it's like giving them a voice to making, giving them the, um, agency to, to write the questions and be the like, be the ones to contribute... And in that process, they were collecting data, they were, um, you know, who picked yes, who picked no, who's in the middle."

Here we see that Ronald's epistemic stance codes students' resources as assets to discussion. When describing this low point in classroom discussion, Jeff frames himself as the driver of discussion and knowledge disseminator. In a narrative about a low point in discussions Ronald describes as:

> "And I think I was also at a place personally and like mentally where, um, I, I couldn't think of thoughtful feedback. Like I, they, and they would ask for help and, "Okay, tell me your question" and I sit there and I'm just like, "Oh, I'm just as stuck as you"...Um, they're not getting my help, uh, I'm not even providing help."

In contrast to Jeff, Ronald's places his role at the center of what he coded as a low point. He interprets a moment where he had challenges supporting their thinking in discussion as a point of failure. In addition centers idea development as what matters to him the most about what happens in discussion, e.g. "what mattered to me was like that development, you know, and like the development of one's ideas." He highlights the importance of the skills of argumentation for the negotiation of ideas, and his desire that students will learn these thinking practices through engaging in discussions.

Discussion and conclusion

This study investigated teachers' frameworks about science discussions and the relationship between the interpretive schemas they adopt to frame discussion in their classes and instructional decisions about how to facilitate them. By contrasting the case of Jeff and Ronald, we see that whilst teachers' might code forms of participation as productive in discussion, they can differ in interpretative schemas employed to make instructional decisions.

What connects what Jeff notices about salient high points and low points, how he makes sense of and reasons about these moments, what meaning he derives from them (coding), and then subsequent instructional moves he makes, center on the framework, that *students need to meet him where he is*. Thus he conceptualizes the discussion as a context where students should demonstrate that they know what he knows. Despite the experiences and knowledges that students may have brought with them into the classroom, Jeff does not code them as useful in the discussion. This is significant, in light of research that shows how carefully guided discussion can not only support students' knowledge and conceptual understanding, but that the process of joint construction of knowledge and negotiation of meaning is productive for the development of reasoning itself

(Clarke, Resnick & Rosé, 2016). Thus, this framework seems to inform Jeff's interpretations of experiences in discussion where students do not seem to rise to his standard, as moments of failure and not productive.

What connects what Ronald notices about salient high points and low points, how he makes sense of and reasons about these moments, what meaning he derives from them (coding), and then subsequent instructional moves he makes, center on the framework that he needs to *meet the students where they are.* His attention seems to be organized around making sense of what students need, what they know and what he can do to support them so they engage and learn. Ronald seems to be engaging in the ubiquitous work of understanding where students are and making instructional decisions dynamically and reflexively to attend to student learning. Further, Ronald's framework seems to center his own agency in supporting student learning, acknowledging that he has the capacity to make alterations in discussion to increase student learning and participation.

How Jeff and Ronald frame these discussion events directly impacts the opportunities for engagement that students are afforded in classroom discussion. In Ronald's classroom students are given space for exploration, whereas Jeff's focus on knowledge may potentially lead to decisions that decrease the opportunities for students to engage in discussion. This understanding allows us a glimpse into teacher cognition and reasoning.

Our analysis shows that when a teachers' framework attunes to engaging students in argumentation as an intellective and social practice, their instructional decision making focuses on scaffolding that process. Conversely, when their framework attunes to science as an acquisition of knowns, then their decision making seems to center instructional moves that focus on disseminating and validating these knowns.

Our work focuses on teachers' frameworks as a means to ground teachers' ongoing professional development around their sense-making about classroom discussion as a form of learning. Surfacing teachers' existing and emergent interpretive schemas about aspects of practices may help to support teachers to engage in critical reflective practice about what they notice, highlight and the forms of participation they value, and how their decision making is tied to that reasoning. In our work, we are leveraging these insights to map the design space for personalized professional development on facilitating science discussions that engage students in sense-making about science.

Identifying the Practices of Girls' Maker Hobbies: The Case of Doll Makeovers

Priyanka Parekh, Transylvania University, pparekh@transy.edu

Abstract: Making is a popular endeavor and a rich learning opportunity for children. Yet, we know very little about how children self-initiate and pursue making as hobbies, and the value of such engagements as learning opportunities. To support STEM learning in relevant, familiar contexts for all interested children, we need to know the diverse experiences that support maker hobbies, including those not immediately apparent as STEM-rich (Bevan, 2014). I describe three young girls' doll makeover projects where they fix old dolls and make clothes and accessories for them as a maker hobby. Conceptualizing maker projects as representations, I examine the girls' practices as they give makeovers to old dolls throughout a summer break. Using a qualitative content analysis method, I identify Maker practices as a combination of STEM, literacy, social practices, and making as a hobby situated in the fabric of young girls' interests and contexts.

Introduction

Maker education research, just like the nature of making that youth engage in, is extensive in scope. The bulk of the research in making and learning concerns a pedagogical approach to developing students' interests, capacities, and productive learning identities by building and exploring ideas. Although this educational approach breathes new life into STEM education by emphasizing learning by doing as opposed to by reading only, it is distinct from making as a hobby that children pursue solely out of interest. Diverse ways of making and the related skills and practices are critical to our understanding of STEM as practiced by children and the merit inherent in such activities.

Despite the continuous and well-intentioned efforts, we continue to associate a restricted range of knowledge and practices with STEM learning. Our understanding and acknowledgment of STEM learning is also related to gender and identities (Gutiérrez, 2013), and tools, materials, and technologies (Searle & Kafai, 2015) with histories in and of themselves. Disconnects between these two sets of attributes can discourage youth from engaging in STEM (Calabrese Barton et al., 2013). Based on this rich knowledge of making, gender, and STEM learning, I describe three young girls' experiences passionately pursuing a doll makeover hobby over a summer break. I illuminate their interest-based making as a rich learning experience and answer the following research questions.

1. What constitutes girls' interest-based maker practices?
2. How do these practices relate to other interests and skills that the girls have?

Making as a way of STEM learning has been welcomed by the education community to engage learners with a wide range of STEM learning interests. Application of STEM practices, processes and phenomena are possible in a range of contexts beyond robotics and 3D printing. For example, Calabrese Barton & Tan (2018) recognized that cooking and embroidery projects could have some STEM orientations in unique ways. Halverson (2013) examined digital art as representations of the sense-making process. Studying making as a hobby affords new opportunities. First, it helps us study making in natural settings and document the many ways in which children use technologies that are available to them. Second, technologies that have become popular because of widespread interest in educative making have been used to educate youth, but in projects and ways we deem suitable. However, related activities such as crafting with available resources have received little attention. Owing to this gap, we don't know about the other uses of these technologies, situations in which they become meaningful, and the skills children employ to use them. Children's own interests in making is a rich domain of practice and merits scholarly attention.

Maker projects as representations and constructions

Research on making and maker practices draws from a range of settings, material and technological resources, and educational contexts. To bridge children's making across these domains, I first examine the conceptualization of maker projects. Maker education research values maker projects as constructions (Papert, 1980) - objects-to-think-with that lie neither solely in the head nor in the world but rather at the intersection of the two and relies on the general constructivist idea that children actively build ideas that represent what they know of the world around them. Through the creation of representations, artists are known to transform the materials and express ideas (Eisner, 2002, p. 80). Designers abstract irrelevant details in the process of creating representation as a valuable experience (Norman, 1993). Overall, experts across these domains agree that the process of creating representations is an iterative one that compels creators to address assumptions, test new knowledge, identifying problems, and look for solutions. I conceptualize maker projects as representations that require the use of tools and materials, as engagement in habits of thinking, practices, cultures, and contexts, and as documentation of our knowledge of the natural and material world.

Making, STEM learning, and gender

That a restricted approach to making and makerspaces might reinforce the existing gender disparities and stereotypes in STEM fields concerns many. Initiatives to combat such a disadvantage include raising awareness of the lack of representation of women in maker movement press, organizing all-girls Maker clubs, and offering workshops designed to further girls' technological fluency in working with e-textiles. Some scholars (for example, Sengupta-Irving & Vossoughi, 2019; Calabrese Barton & Tan, 2018) have criticized the deficit perceptions of STEM participation that often shape girls' experiences in STEM including the suggestion that girls *can* and *should* engage in STEM the same way as boys do, that special spaces be created for girls because they *must* pursue STEM careers, and that girls of color *need* to be STEM practitioners to gain access to a better life. These suggestions highlight the belief that choosing certain kinds of STEM careers reflects a sound judgment on girls' part while ignoring girls' possibility to be interested in other kinds of STEM or not be interested at all. In studying doll makeovers as a maker hobby, I consider girls' making a domain unto itself worthy of scholarly pursuit. In the following sections, I describe the methodology and findings in response to the research question.

Methodology

I examined children's interest-driven making as a collection of multidimensional practices across STEM, Maker Education, and STEM literacy. I employed Maker practices as identified by researchers (Bevan et al. 2014; Wardrip & Brahms, 2015), Computational Thinking practices (Wing, 2006); and STEM literacy practices (Gravel, Tucker-Raymond, et al. 2018). In doing so, I explored making beyond the constructions, the projects to the process of their creation. This is important because STEM includes a wide variety of practices and literacies, but are often ignored in understanding and contextualizing learning. I collected data for this study as a participant-observer and mentor in a series of loosely structured making activities involving my daughter and two of her friends. At the time of data collection, the girls were eleven, nine and eight years old respectively. I considered transcripts of the girls' conversations in the recorded videos, logs of girls' actions on projects supplemented with photographs, transcripts of interviews with them, and extensive field notes as data. I conducted content analysis (Schreier, 2012) with two attributes of the girls' work in mind - a) making processes and b) maker practices with the meaning unit as the unit of analysis. I began with an inductive approach and open coded the data using definitions of the practices. I then used thematic content analysis (Carley, 1990) to compare these instances to understand the nuances of these practices. Later, I applied this understanding in a second round of coding involving fewer practices with related practices collapsed in suitable ways. Finally, I organized our findings into three categories - STEM thinking and learning skills, literacy skills and social skills. Once I had identified the findings, I shared and discussed the findings with the girls as a way of member checking (Lincoln and Guba, 1985).

Findings

Doll makeovers as a hobby comprised of several pre-existing interests that the girls already had. These include playing with dolls, digital art, printing on transfers, slime making, play dough constructions, and 3D art using 3D pens. Doll makeovers include repairing old dolls (untangling doll hair, cleaning the dolls by removing stains carefully, etc.) to give them new looks by changing their hairstyles and clothing, making new clothing from scratch, changing their skin tone, and replacing them hair, and facial makeup.

STEM maker practices

The girls purchased doll clothing patterns on Etsy stores run by older women trained seamstresses and experts in pattern making and aware of the many dolls. With no experience in using patterns to make clothing for dolls, the girls faced steep challenges. First, they had to learn to "read" and use a pattern, and second, they had to learn to modify the patterns for dolls of different shapes sizes. For example, patterns for clothes for Barbies did not fit other dolls (Ever After High, Disney princess dolls, and other unknown types) well. Realizing the need for modified patterns, the girls adopted a few trial and error approach. The girls eventually tried out all three ideas and finally found a way to create their own doll clothes patterns using masking tape. Overall, they could either consider the dolls' proportions or the pattern measurements to make clothes that were to scale. Their approach to look for "a pattern (of solving the problem) to make patterns" required them to understand the problem as a combination of not knowing the rules and a lack of skills. To solve the problem, they used the practice of abstraction that later helped them understand patterns better. Further, in their pursuit of making doll clothes alone, the girls made and traversed multiple representations created by practitioners and transitional ones that they created for their own use. As the girls explored the digital drawing tool, they talked about a digital drawing tool's unique affordances in contrast to paper and pencil drawings. The girls explained technical concepts such as that of layers to each others, weighed their options when using the digital drawing tool while not compromising the desired visual effect , and acknowledged that "it takes time" to explore a "dense" tool thoroughly. Each of the girls explored the drawing tool to meet her individual goal.

Literacy practices

Across their projects, the girls switched back and forth between identifying goals, seeking information relevant to those goals, experimenting with applying the information to physical objects and tools, and seeking further information when problems arose in their work. The girls' work on doll makeovers was iterative; despite the range of information and inspiration available on YouTube, the girls had to make room for their inexperience and the lack of specialty supplies. For this reason, their work was heavily shaped by emergence. Throughout each of their many projects, they actively sought and evaluated information from various texts (e.g., websites, product descriptions, images, instructions); their ability to locate relevant information was crucial to each project's success and how they planned to further their interest. Making draws on multiple domains and a crucial component of literacy practices involves identifying relevant knowledge domains and communities (Gravel et al. 2018).

Social skills

Each girl positioned herself as an expert or novice concerning each of their hobbies and assumed an expert's role, a fast-progressing learner, and a novice. When they needed help locating and procuring fabric and thread and needles for the clothes, they sought assistance from their grandmother, an expert seamstress who later taught them to take apart doll clothes to create clothing patterns carefully. The girls explained processes and problems and provided and made sense of information for each other. In doing so, they collaboratively constructed their activities in a way that allowed them all to assert their opinions and ideas. Further, the roles they assumed while working on each project shaped how their social interactions with each other and adults unfolded. Having described the practices that the girls engaged in as they pursued interest-based making through doll makeovers, I now describe how these practices were embedded in their everyday lives and related to their other interests and skills.

Maker hobbies as lines of practice

The above observations indicate that interest-based making is a line of practice – "a distinctive way in which a person's preferences are attuned, over the long haul, to specific conditions of practice"(Azevedo, 2011). The girls' persistence in making as one line of practice was also attuned to the context and practice conditions (support for children's independent, playful engagement, supportive adults, access to materials and tools, and their mutual support), and their more extensive repertoire of practices and skills. Each girl had developed skills in the pursuit of an existing interest; working on doll makeover was the context in which these skills gained relevance.

Making as a collection of complementary identities and practices

The girls were novices in some areas and experts in others, even within their work on one project. Each girl was a novice in some tasks (pattern making and sewing), tools, and technologies and well versed in others; their identities of expertise were complementary and the tasks they performed were complementary too. Based on the above analysis, we see that the practice of interest-based making, such as doll makeovers requires youth to implement STEM thinking skills such as abstraction, problem decomposition, and traversing multiple representational forms, and posing and solving problems in a process, as well as literacy practices and social skills.

Discussion

A frequently stated goal of maker education is to help youth develop STEM interests and identities and potentially venture into STEM careers. That informal childhood experiences in science often spark initial interests and identities as scientists is widely acknowledged. I have demonstrated that children can engage deeply and meaningfully in STEM literacies through self-initiated maker hobbies that are not traditionally thought of as STEM.

One implication of these findings for educators, parents and mentors in informal settings is to find ways to find out and understand the richness of children's experiences at home and with peers so that these can form the basis for science education and connecting students to relevant communities of practice. Additionally, the girls' practice of doll makeovers indicates that identities, too, are relevant to such an embodied experience. These findings iterate what we already know of identity as malleable, tied to circumstances and social contexts, as well as individually constructed. Studying girls' hobbies brings an opportunity to study their STEM engagement as multidimensional and involving multiple intersecting social identities beyond the usual stereotypes surrounding the conceptualizations of both STEM activities and identities.

Improvisational Dance as Enactive Cognition

Lindsay Lindberg, Ananda Marin
lindsay.lindberg@ucla.edu, amarin1@ucla.edu
University of California, Los Angeles

Abstract: We show the ways an improvisational dance workshop provided the opportunity for participants to be autonomous actors and engage in embodied sense-making through dance – two key parts of the conceptualization of *enactive* cognition. As part of a Design Based Research study (DBR Collective, 2003) we use Interaction Analysis (Jordan & Henderson, 1995), Diagrammatic Transcripts (Lindberg & Marin, 2020) and in-depth qualitative analysis to present examples of autonomy and agency in dance learning in a contemporary art museum. We describe the interactions of two pairs engaging in a designed dance activity, and the ways their improvisational movements highlight the ways in which dance is a tool for sensemaking.

Introduction

We present data in which an improvisational dance workshop provided the opportunity for adults to be autonomous actors, and engage in embodied sensemaking through improvisational dance. Improvisational dance as a learning activity has been studied by many, and has no simple definition (De Spain, 2014). For the purposes of this paper we define the term improvisational dance as an activity in which people participate as active agents and observers (Dils, 2007) and generate spontaneous movement in creative play and exploration (Lord, 2001; Blom & Chaplin, 1988). Building on research on enactive cognition (Menary, 2010) and analyses of collaborative dance making as a cognitive process (Giugere, 2011), we ask two questions. First, how do we see autonomous activity and sense-making (components of enactive cognition) in improvisational dance? And second, what methods allow us as researchers to represent dance - aesthetic, embodied movements - as cognitive acts when making sense of art in a museum?

4E cognition in relation to dance

4E cognition aims to explore the role of the whole body in interaction with a context - how bodies embody, embed, extend, and enact with and in their environments. Enactivists in particular conceptualize learning as "whole-body engagement" (Gallagher & Lindgren, 2015, p. 391) through autonomy and embodied sensemaking. Despite this, the ways in which the "whole-body" is conceptualized is typically not attended to in education with the nuance that dancers bring. Cognitive processes, according to 4E scholars, are not separate from the body and environment but are influenced through interaction with the physical and social world (Menary, 2010). This is especially relevant for this analysis of improvised dance, as an embodied conceptualization of learning has long been held by dancers (Snowber, 2016). While tensions between dance theory, 4E cognition and embodied cognition are clear throughout the literature, at the center of each field are similar assumptions about cognition and interaction - that movement influences the act of making sense of interactions with the world. This paper positions dance as an *enactive* process looking at two key aspects: autonomy and sensemaking.

Autonomy in dance

Described by enactivists, "[a]n autonomous system is defined as a system composed of several processes that actively generate and sustain an identity under precarious conditions" (De Jaegher & Di Paolo, 2007, p. 487). We extend the idea of an autonomous system by drawing upon literature exploring autonomy in language learning (Toohey & Norton, 2003; Little, 1995) to expand the ways in which autonomy can be seen in learning interactions, specifically through dance. In these conceptualizations of autonomy in learning, the individual takes on active roles of engagement with the material – applying their learning from formal schooling contexts to their lived experiences. The learners in this paper demonstrate autonomy through improvisational dance choices in location, spacing, speed, and movement – making their thinking and sensemaking physically visible, and therefore actionable, for their peers and analysis.

Participatory sensemaking in dance

Autonomous beings, as described above, interact with themselves and the world by actively making sense of their surroundings. *Participatory sense-making* (De Jaegher & Di Paolo, 2007) regards social cognition and interactions as central to the concept of enactive cognition. Hanne de Jaegher (2013) describes participatory sense-making as "the coordination of intentional activity in interaction, whereby individual sense-making processes are affected and new domains of social sense-making can be generated that were not available to each individual on her own" (Cited in Hermans, 2019, p. 23). Dance provides a unique context in which to study enactive participatory sensemaking, as we have social, interpersonal, intrapersonal, and interactive responses magnified through the visibility of danced movements and audibility of verbal utterances.

Cognition as a collaborative process in dance

We draw on work that emphasizes the collaborative nature of cognitive processes like choreographing and improvising movements (Rogoff, 1998). This is an important distinction, as much of the research on dance and cognition (e.g., Giguere, 2011) and cognitive science has studied individuals engaging in the creative process (Moran & John-Steiner, 2003). Recent research on creativity in the learning sciences (Sawyer, 2005) attends to the more collaborative nature of learning (Enyedy & Stevens, 2014), which this work builds upon - using collaborative dance and enactive cognition as a site for thinking, learning, and creating.

Methods

This Design Based Research Project (DBR Collective, 2003) positions postmodern and improvisational dance as enactive resources for learning in the context of a contemporary art museum. In partnership with a staff member at the museum, we designed a 90-minute dance workshop that was implemented for 15 University students learning to become museum docents. Participants were between the ages of 19 and 35 and each was a paid employee at the museum, participating in a docent training program. We collected video data from the intervention using four Go-Pro cameras that were placed in different locations in the gallery. This paper reports on our analysis that we hope to use to inform future iterations of the workshop.

The workshop design

Closely inspired by Liz Lerman's postmodern conceptualization of dance (Borstel, 2007) that every action can be done with intention, each movement can be a dance, and dances take up space and shape, we designed a series of dance improvisation games to promote engagement with and observation of artwork in an art gallery. After a mindfulness warm-up, an improvisational dance-based "mirroring" practice moved into a "See and Move" designed dance game, and finally participants engaged with a "Docent Dance" exercise with a partner. All four elements of the workshop invited participants to improvise and share postmodern dance movements inspired by the visual art in the gallery and were followed by discussion and written reflection. These activities were designed as low-stakes entry points to begin improvising movement spontaneously, being physically alert, and relating to a partner while in motion. In the remainder of this paper we report analysis on the "Docent Dance" design.

Data analysis

Using interaction analysis (Jordan & Henderson, 1995), diagrammatic transcripts (Lindberg & Marin, 2020), and the lens of movement as enactive cognition, we analyzed the "Docent Dance" design. The first author viewed the video from the 90 minute workshop and content logged in 30 second increments. Participants' physical location in the gallery, what designed activity they were participating in, who they were with, the scale of their movements, and verbal utterances were all noted. Attention was paid to participants who were in full view of the cameras when participating in each of the designed activities. We then traced all 15 participants' physical locations in the museum gallery using diagrammatic transcripts (Lindberg & Marin, 2020) to understand their facings and location over the 90 minutes. Through an inductive analysis of the data, moments of interest were identified in which participants improvised dance movements and described their sensemaking verbally. These instances were analyzed using Interaction Analysis and then cross-referenced with interview transcripts, and students' written reflections during the workshop. In this paper, we focus on the ways in which both autonomy and participatory sense-making are seen in one activity, for two pairs playing the "Docent Dance" game.

Major findings

This section presents an analysis of two pairs of participants from the data corpus making sense of the same piece of art. We also show how we used both interaction analysis and diagrammatic transcripts together to represent dance as a form of enactive cognition. In each instance, we see dance as a context for cognition, as learners demonstrate autonomy and participatory sensemaking. We also demonstrate the ways in which diagrammatic transcripts are useful as a tool of analysis with which to add depth and rigor to an analysis of improvisational dance in representing bodily positions.

Autonomy and sensemaking In the Docent dance: Case 1

In Figure 1, we see Partner 1 acting as the docent, engaged in both autonomous activity and sense-making through improvisational dance. She first demonstrates autonomy by selecting the artwork she wants to guide her partner to. Out of the more than 60 pieces on display in the gallery, she chose this piece. She then transformed the rules of the game by adding a traveling element - she took three long, low-level running steps to her left, before she struck a final pose. This change in location is represented in the diagrammatic transcript 1.1 to 1.2. While the transcripts look similar, the movement is significant for the experience and sensemaking of the pair. They are still in front of the painting, but they have traveled, which we analyze as an autonomous choice made while engaged in improvisational dance in response to the artwork.

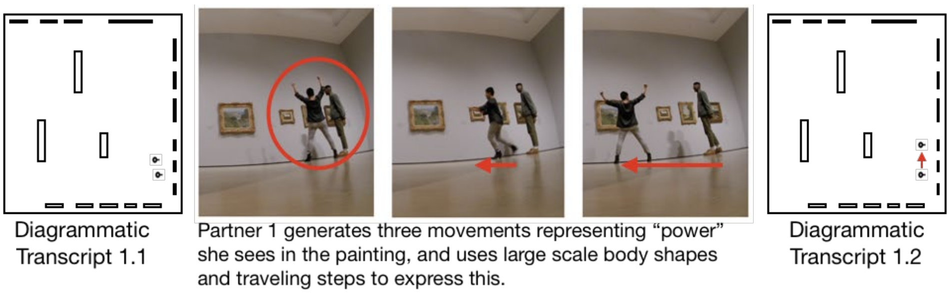

Figure 1. One pair of participants, Partner 1 and 2, use improvisational dance during sensemaking.

After verbally describing what Partner 1 interpreted from the piece (per the *Docent Dance's* design), she improvised a dance sequence demonstrating her sensemaking. She represented the "power" she saw in the painting with strong, large-scale movements with her arms raised over head and her legs wide, feet planted into the ground. We regard this as sensemaking because she actively transformed what she saw in the painting into her own movement as an active, autonomous agent in the environment, rather than mimicking the painting or gesturing towards an element in the artwork. Her sensemaking is recognizable here in part through her verbal descriptions of the "power" and strength in the painting into a movement phrase which she shared with her partner. Autonomy and sensemaking were both recognizable in this interaction because of the designed nature of the workshop.

Autonomy and sensemaking In the Docent dance: Case 2

For the second case, we present a second pair of participants in front of the same artwork. Their starting position seen in the diagrammatic transcript 2.1 is similar to the first pair, however the movement responses and sensemaking were quite different. In this case, Partner 1 stood in a split stance with her left foot forward, right foot back, arms positioned at an upward angle towards the painting – right hand cupped as if embodying the shape of a shell, as the left hand caressed the right hand, exploring the crevices of the concave shape (Figure 2B). She shared with her partner that she was responding to the seashells carved into the frame of the painting, which she had not noticed before. This careful embodied attention to a newly observed portion of the artwork – a pattern of carved shells on the frame of this painting – was brought into the conversation after engaging in dance-based observation protocol. The movement response required close observation, autonomous decision making, and enactive sensemaking.

Figure 2. A second pair of participants use careful attention to detail when observing an artwork.

Analytic precision with interaction analysis and diagrammatic transcripts

By comparing the diagrammatic transcripts of all participants in the workshop, we were able to see where there was overlap, and which pairs autonomously chose to visit which paintings. This allows us to compare the different autonomous choices and sensemaking strategies used in response to the same artwork. Both cases attended to the same painting, and the diagrammatic transcripts look very similar. However, participants observed, commented on, and improvised very different dance movements. Thus, interaction analysis in conjunction with diagrammatic transcripts helped surface the expansive ways we can understand dance as enactive cognition.

Discussion and conclusion

This article aims to build on the conceptualization of dance as enaction, attending to the ways in which dance supports thinking, learning, and interaction. Positioning improvisational dance as a tool for demonstrating autonomy through movement, and sensemaking in response to external stimuli (visual art) makes improvisational dance more accessible to a broad audience of learners. We have endeavored to describe how dancing provides an opportunity for participants to actively engage with themselves, their surroundings, and provide examples of how dancing *is* thinking – not merely a representation of cognitive thought. This research aims to demonstrate both the ways enactive cognition can be used as a lens to view dance as a cognitive act, and the ways in which both diagrammatic transcripts and interaction analysis can support a rigorous approach to an analysis of improvised dance movement as a cognitive act. Newly designed methods can help to support data collection and analysis methods for consequential improvisational dance movements moving forward.

Integrating Data Literacy into Secondary School Science: An Exploratory Study of a Pilot Professional Development

Katherine Miller, Susan Yoon, Jooeun Shim, Amanda Cottone
kmmiller@gse.upenn.edu, yoonsa@upenn.edu, jshim@gse.upenn.edu, amandaco@sas.upenn.edu
University of Pennsylvania

Abstract: In our data-rich world, data literacy is becoming an increasingly important goal in education as data sets become bigger, and more complex. However, data literacy falls outside the traditional topic domain of secondary science curricula and so may be beyond the scope of the pedagogical content knowledge (PCK) of teachers who have received training in only one subject area. This paper presents an exploratory study of how secondary school science teachers learn and use the content and skills of integrating data literacy into their curriculum, within the context of a PD program for bioinformatics. The findings suggest that there are a separate set of PCK components that teachers need to master in order to successfully teach data literacy, and that successful PD must support teachers in developing them.

Keywords: data literacy, pedagogical content knowledge, professional development

Introduction

In our data-rich world, there are strong calls for greater focus on data literacy within education (Gebre, 2018; Gould et al., 2016; Rubin, 2020). Though it is interdisciplinary in nature, data literacy suffers from being nebulously defined and having no clear home within the traditional secondary school subject-based curriculum (Gebre, 2018; Lee & Wilkerson, 2018). As integration of subjects has been shown to present a challenge to teachers who have received training in only one subject area (Aslam et al., 2018), teachers may need additional support to develop knowledge and skills for teaching data literacy, also known as pedagogical content knowledge (PCK) (Neumann et al., 2019). Data literacy as a component of teacher education is a relatively new concept. As the way we interact with data through increased technology exposure, and greater computing power changes, the way we seek to teach students to interact with data also needs to change to promote a broader relationship with data (Lee & Wilkerson, 2018; Wise, 2020) and a greater focus on the context in which data is collected and used (Rubin, 2020). In this study, we sought to better understand how PD can support teachers in developing PCK for data literacy. Through analysis of interviews, surveys, and classroom observations we asked, how does a PD program for bioinformatics support teachers in learning and implementing the content and skills of integrating data literacy into their science classroom and existing curriculum?

Background

Researchers and practitioners are thinking about what it means to teach data literacy and what the pedagogical implications are for integrating data into the classroom (Gould et al., 2016). Wilkerson and Polman (2020) outline two core pedagogical commitments for teaching with data. (1) that teachers should be flexible with learning and promoting new tools and methods for working with data, and (2) that data based teaching should be grounded in full cycles of inquiry using real, consequential data. Lee and Wilkerson (2018) also support the notion that work with data should be conducted within the context of meaningful scientific investigations, and add that the interdisciplinary nature of data should be highlighted with connections between math and science classes, and that the complex and dynamic nature of data should be explicitly discussed and multivariate relationships explored. Since training for secondary school teachers is often specialized by subject, these pedagogical skills may be new to many teachers (Aslam et al., 2018) and require new PCK. A review by Neumann and colleagues (2019) offered a consensus definition of PCK as "teachers' personal knowledge that drives their planning for, implementation of, and reflection on instruction" (p. 856). In merging knowledge of pedagogy and knowledge of content, PCK is topic specific, which can hinder a teacher in integrating new content material that may fall outside their learned topic domain (Aslam et al., 2018). Data literacy currently exists in that space outside of traditional secondary school topic domains (Gebre, 2018) and as such, most science teachers are not supported in developing PCK for data literacy. Additionally, data literacy as a concept is still being defined which further complicates efforts to support teachers in integrating it into their classrooms

Data literacy is an emerging concept without a clear definition or set of core competencies that are widely accepted across different fields (Wolff et al., 2016). A recent review of literature on data literacy attempted to synthesize a working definition of the concept as "the ability to ask and answer real-world questions from large and small data sets through an inquiry process, with consideration of ethical use of data" (Wolff et al., 2016, p. 23). However, this definition leaves space for a number of different competencies, especially as data sets become more complex, and as students become participants in data creation (Gebre, 2018; Wise, 2020). In their report on data use in secondary school, Lee and Wilkerson (2018) begin to create a framework for some of these competencies which could help in defining PCK for data use. They outline four understandings that are required to develop data literacy: a) *measurement and sampling*, b) the *characteristics of data*, c) different types of *data representation*, and d) *making inferences from data*. Rubin (2020) supports these themes, and adds a fifth understanding, which is e) *context*, the who, when, where, what, why and how of data collection and use.

Defining competencies that lead to development of data literacy is a helpful step leading to integrating data literacy into science classrooms, but teachers also need to be supported in learning these competencies and developing PCK for data. Though research has shown that PD can enact change in teachers' practice (e.g., Darling-Hammond et al., 2017), it is important to design PD in a way that is mindful of the unique challenges posed by promoting data use in science classrooms. Lee & Wilkerson (2018) lay out a number of recommendations for improving teachers' knowledge and practice when it comes to working with data in the classroom. These include: providing extended time for teachers to use the technology through a full cycle of inquiry; highlighting that though technology and data-based inquiry can be used to teach content, additional data literacy skills also need to be taught in order for content learning to be achieved; and provide case-study examples of students working with data and technology. Where we know that integrating data literacy in science education content has presented challenges, teachers will need support for developing PCK in PD opportunities. For this reason, considering high quality PD characteristics (Darling-Hammond et al., 2017) is important.

Methods

This is an early stage, exploratory study that draws on qualitative data from a small pilot group of teachers. The goal of the full project is to support teachers in implementing a problem-based learning (PBL) curricular unit that challenges students to come up with data-based solutions for addressing asthma rates in their urban district. The curriculum requires reasoning with less traditional data sources such as that collected by digital sensors, and that available in large public data sets (Lee & Wilkerson, 2018).

Designing for data literacy

The PD was designed and developed in the winter and spring of 2019 and implemented over three weeks in July 2019. Teachers attended in-person for 6 hours of learning time each day, for a total of 90 hours. Of those, about 7 hours were devoted to data literacy. Data literacy instruction utilized five primary activities: a) defining data literacy, b) learning new tools for working with data, c) working with data as a learner, d) reflecting on learning about data, and e) reflecting on teaching with data. These activities were based on design principles for high quality PD and emerging theories on developing data literacy as outlined in the above section. In defining data literacy, participants explicitly highlighted the need for data literacy skills while grounding learning in the context of their classroom. The PD engaged participants as active learners while learning a new app for data analysis. Participants worked in pairs to conduct a full cycle of data collection, analysis, and communication of results, using student-facing materials from the example PBL unit. The PD provided time for reflection both on the process and experience of learning with data, and on how to apply what they learned to strategies for teaching with data in their classroom. All data literacy instruction was grounded in a community level scientific problem (high asthma rates in urban areas) and structured around a full inquiry-cycle to address that problem. Throughout the PD, the facilitators modeled effective instructional practices and encouraged collaboration.

Participants

The pilot study consisted of six teachers from a large urban school district in the northeastern US where over 85% of students are racial minorities and 100% of students are considered economically disadvantaged. Three of the teachers taught biology and three taught environmental science. Three of the participants identified as female and the other three as male. Half of the participants identified as Black and the other half as White. They had an average of 9.8 years of experience ranging from 2 to 18 years.

Data sources and analysis

The sources for this study consisted of surveys conducted pre and post PD, external evaluator memos from focus groups during the PD, classroom observations during implementation, and interviews conducted post implementation. A content knowledge survey which included a set of questions about teachers' understanding of data literacy and their pedagogical practices was given at the beginning and end of the PD. On the last day of the PD, participants were also asked to complete an Evaluation Survey of the PD experience with a few questions specifically aimed at the data literacy content. The external evaluator on the project conducted focus group interviews with the participating teachers three times during the PD (Day 1, 5 and 10) and wrote up notes summarizing themes with supporting quotes that were shared with the research team. Classroom observations were conducted throughout the school year by different members of the research team. At the end of the school year, semi-structured post-implementation interviews were conducted with five of the six teachers which included questions that asked teachers to reflect on their teaching and their students' learning.

The data was qualitatively mined for articulations of data literacy themes in order to study the pilot run of the PD and teachers' impressions of it and success with implementation. There were some prompts in the surveys and interviews that specifically asked about impressions of the data literacy content, and these were used to frame pre and post self-reported beliefs from the six teachers. These beliefs and experiences were then compared to observation notes from classroom implementation to determine the fidelity with which the data literacy components of the curriculum were enacted.

Findings

Three primary themes were drawn from the data analysis: a) teachers came into the PD with hesitations about working with data; b) the PD helped some but not all teachers feel prepared to teach with data; and c) teachers encountered a number of challenges in implementing integrated data literacy content.

Initially, teachers demonstrated hesitancy in working with data. The pre-surveys showed that five of the six teachers held a traditional view of what working with data means in a classroom, highlighting skills such as analyzing data and creating graphs, with only one participant linking skills to larger ideas such as solving problems. This focus on discrete steps for working with data is evidenced in this typical response from the pre-survey: "[Data literacy is] the method individuals use to collect, interpret and analyze data. This can include building data tables, using variables and/or drawing graphs." Though all six teachers indicated that they had worked with data in their classrooms previously, they came in with a range of experiences for how often data was used in their classrooms, and the level of rigor it was taught with. Throughout the first week of the PD, teachers expressed nervousness about the data literacy components of the curriculum, with one teacher on the first day saying, "The most difficult aspect will be helping students analyze data and interpreting graphs. This is something that they have rarely, if ever, done in their life." Additional notes from the focus group interview on day one support this quote, stating that "they [the teachers] mentioned students struggling to understand the X and Y axis of graphs. They rely on math teachers to teach graphing; they feel insecure in doing this themselves." This shows that they were expressing uncertainty about certain aspects of data collection and analysis.

By the end of the PD, in the post-surveys, teachers showed more confidence than they had at the beginning and midway through the workshop. When asked about the efficacy of the data literacy component of the PD, all six teachers responded positively, suggesting that the goals of the PD were met and that teachers felt they had learned something useful for implementing data literacy instruction. When asked what additional support they would need in order to implement the PBL curriculum in their classroom, most teachers said they felt prepared to teach, however some of them mentioned that they were still feeling insecure, such as the teacher that wrote in response to a prompt about foreseen challenges for implementation, "the most difficult challenge will be data analysis, and chart making. I just foresee the students having difficulties... and with my own insecurities about the topic." There were hints that more teachers felt this way than chose to admit it. In response to the question *What would you have liked to spend more time on?*, universally, teachers requested more time with data collection and analysis and "More practice analyzing and creating graphs." So, despite praising the PD for adequately preparing them to teach data literacy, most teachers desired more time to internalize the concepts.

The fidelity of the data literacy components during implementation was low. Though teachers were encouraged to modify the example curriculum to fit the needs of their students and classroom, every teacher cut out at least some of the data literacy components, with some teachers skipping entire lessons and sets of objectives. During the lessons that were observed, many of the teachers struggled with aspects of working with the data. As in the following example where the researcher noted that their "Overall impression of Tamara' data analysis class is that only a surface level of data analysis (getting average) is being taught. Tamara looks a little discouraged since she has been struggling with facilitating these lessons with students." As the teachers struggled to implement the data literacy components of the unit and cut back on the activities and lessons being presented to the students, the bigger picture of the meaning and relevance of data to real-world problems got lost. Teachers fell back on approaches to data literacy that they were comfortable with, which deprioritized focusing on the meaning and relevance of the data sets for exploring real world problems. Together, these findings showed that teachers felt underprepared to teach data literacy in their science classrooms, and though a three week intensive PD helped them to feel more prepared, that increase in confidence did not translate into effective teaching of data literacy.

Discussion and implications

In this preliminary study, the goal was to highlight themes that would help guide the researchers in modifications to the intervention and further support for teachers in developing PCK for data literacy integration. The analysis of data sources tells a story that aligns with common pitfalls of PD (Darling-Hammond, 2017) and the limited literature on teachers engaging with data literacy concepts in their classrooms (Lee & Wilkerson, 2018). By studying how teachers learned and implemented data literacy integration, this research has highlighted the ways in which the PD failed to adequately support teachers in integrating data literacy into their science classrooms, and in the process uncovered the need to focus more on PCK development. Teachers entered the PD a little wary of the data literacy and technology components. They reported learning a lot during the PD and feeling prepared to teach, while simultaneously wishing for more time to grapple with data literacy concepts. However, once they were in the classroom, the confidence faltered, and they mostly fell back on more traditional and conservative understandings of data literacy that divorced the data engagement from the content and framing problem.

The designers and facilitators of the PD overestimated the extent to which teachers would be prepared to implement the data literacy component of the PBL curriculum. The PD was designed based on assumptions that participating teachers would have knowledge and skills about the complexity of data and tools for data analysis that would translate quickly onto the new technology and data sets. However, the challenges that teachers faced in implementing align with the two core competencies for teaching with data laid out by Wilkerson and Polman (2020) and suggest that there may be a separate set of PCK components that teachers need to master in order to successfully teach data literacy, beyond those commonly considered part of science teachers' PCK. In order to better support teachers in integrating data literacy into their science classrooms, PD needs to focus on not only the content of data literacy and its' connections to science content, but also on the separate PCK that teachers need to implement with complex data and new technologies. The findings from this preliminary study add to the growing literature (e.g., Wilkerson & Polman, 2020; Wise, 2020) that highlight the need to support teachers in rethinking the way they engage with data in their science classrooms.

Abstract: This paper presents the Critical Action Learning Exchange (CALE), an international professional learning community of educators for development and exchange of Critical Action curriculum, resource sharing, and empowerment of students in responding to issues including climate change, social and environmental justice, pandemics, or economic inequality. Our research focuses on teacher knowledge and learning, and examines the role of a pedagogical framework grounded on Knowledge Building (Scardamalia, 2002) and Critical Pedagogy (Freire, 1970) in supporting collaborative design of curriculum. This paper maps our analysis of our first design cycle to Reeves' (2007) four phases of design-based research.

Introduction

This paper presents the Critical Action Learning Exchange (CALE), an international professional learning community of educators for development and exchange of Critical Action curriculum, resource sharing, and empowerment of students in responding to issues including climate change, social and environmental justice, pandemics, or economic inequality. Our research focuses on teacher knowledge and learning through collaborative design, enactment and reflection about Critical Action curriculum with a theoretical perspective grounded in Knowledge Building (Scardamalia, 2002) and Critical Pedagogy (Freire, 1970). This paper adopts a design-based methodology, explicitly mapping our analysis of the CALE design and first year's activities to Reeves' (2007) four phases of design-based research. We focused on three research questions: (1) How can a professional learning community support teachers in designing curriculum that empowers students in relation to pressing social challenges like climate change, pandemics, racism, poverty and inequality? (2) What forms of materials, activities and technology environments are needed to scaffold such a community? And (3) What is an accessible framework to guide teachers' designs of Critical Action curriculum?

The first design cycle culminated in a 5-week online workshop that established CALE's inaugural cohort, with 60 participants from Brazil, Canada, Colombia, and the United States. During the workshop, teachers engaged in collaborative design of curriculum, reflected about classroom practice and student learning, and discussed pedagogical approaches to Critical Action, defined as the engagement in individual and collective action to produce socio-political change in aspects of society that generate unjust, oppressive, harmful, or unhealthy conditions (Jemal & Bussey, 2018). This paper describes our first design cycle of community activities, scaffolds, and technology environment. It reports on the ideas brought in by initial participants and their progress over the workshop, focusing on teachers' developing ideas, as manifested in their curriculum designs, and discussions related to those designs. We close with a discussion of how these analyses contribute to refinements of our theoretical framework, technology environment, and teacher scaffolds.

The need for critical action

This project grows from an understanding of the current global landscape as a point of confluence of several crises, as reflected by the UN Secretary-General António Guterres in his opening speech of the 75th UN General Assembly:

> *"We face simultaneously an epochal health crisis, the biggest economic calamity and job losses since the Great Depression, and dangerous new threats to human rights. COVID-19 has laid bare the world's fragilities. Rising inequalities. Climate catastrophe. Widening societal divisions. [...] Our world is struggling, stressed and seeking real leadership and action." (Guterres, 2020)*

Each of these multiple crises—environmental, sanitary, geopolitical, economic, civilizational—have a direct effect on students. In recent years, new terms such as *eco-anxiety* (Ojala, 2018) and *climate anxiety* (Wamsler & Brink, 2018) have emerged to describe a range of psycho-emotional responses to the perceived threat of climate change, including worry, anger, and hopelessness. Similarly, these kinds of psycho-emotional responses have been reported in groups and communities worldwide that are particularly affected by other situations perceived as oppressive and overpowering, such as systemic racism and other forms of discrimination, war, poverty, etc. (Ridley et al. 2020; Thabet, Thabet, & Vostanis, 2016; Williams, 2018).

Typical school curriculum addresses such complex socio-environmental problems by helping students understand the mechanics of those issues. But such approaches may have the unintended consequence of reinforcing a passive perspective in which students feel alienated from consequential decision-making and action. Research suggests that anxiety might be alleviated by engagement in some form of committed action (Hoggett & Randall, 2018), indicating that approaches that emphasize students' collective agency and connection with others may help educators counter the potentially damaging narrative of overpowering, insurmountable calamities. Moreover, problems such as climate change and threats to democracies around the world decisively affect the future of the current generation of students. Thus, if a goal of Education is to equip children with the means to thrive in the future, we must emphasize pedagogical approaches that reinforce students' agency and empower students through critical action. CALE aims to respond to this challenge by providing both a pedagogical framework for Critical Action education and a structure for teachers' peer support, in the form of a community of educators engaged in collaborative design, enactment, exchange, and advancement of curriculum that empowers students as agents for positive change.

Methods

Design-Based Research (DBR) is an approach used to improve design practice as well as to enhance scientific understanding of how design affects learning (Barab & Squire, 2004). DBR is well suited as a methodology for this study because it will help produce new understandings, theories, artifacts, and strategies that account for and potentially impact knowledge building in a teacher professional community. Figure 1 shows the first iteration (year) of our research design, structured according to Reeves' (2007) 4-phase framework for DBR. Through this cyclical process, a specific design is informed (phase 1), produced (phase 2), implemented and tested (phase 3), and evaluated and refined (phase 4). In this sense, the designed artifact or intervention becomes, in itself, an important outcome of the research, and an object for further inquiry.

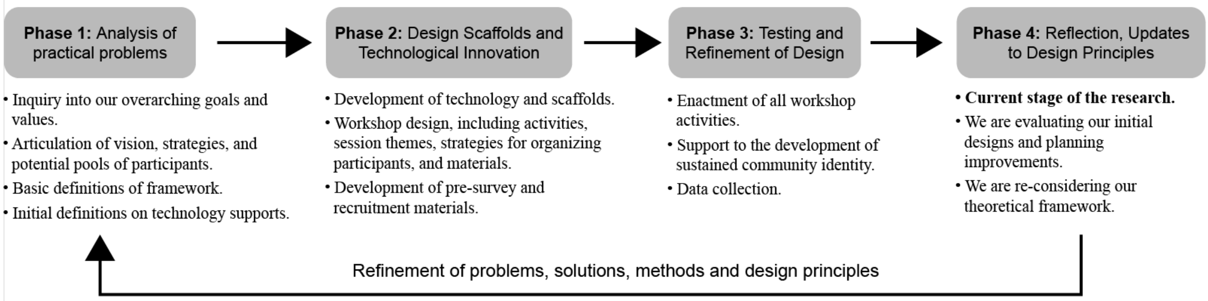

Figure 1: Four phases of our research design. Adapted from Reeves (2007).

Findings

As described in Methods, we present our findings here in terms of Reeves' (2007) four phases of DBR. We focus on the first three phases, as research outcomes, and address the fourth phase in our Discussion.

Phase 1 – Analysis of practical problems

Articulating a theoretical perspective. In Knowledge Building (KB; Scardamalia, 2002) and Critical Pedagogy (CP; Freire, 1970) we identified a set of mutually reinforcing similarities and some important complementary features that offer a solid theoretical foundation for Critical Action education. KB contributes to our approach by proposing a series of practices and principles that foster epistemic agency and collective responsibility to promote continuous improvement of ideas through dialogue and joint investigation (Scardamalia, 2002). CP complements our framework with a philosophy of praxis that stresses the importance of an educative process that interweaves theory, action, and reflection as a means to advance the broader society towards social change and justice (Freire, 1970). CP's commitment to transformative action (Jemal & Bussey, 2018) is articulated around the "problem-posing model" of education proposed by Freire (1970), which intends to reframe inescapable "realities" as actionable "problems".

Conceptualizing goals. A primary goal defined in this phase was to support collaborative design and exchange of Critical Action curriculum. We also sought to support sustained discussions across the community, both within groups of teachers working on the same subject or grade level and among groups to promote cross-cultural collaborations for symmetric knowledge advancement. To support peer feedback and recursive design cycles, we identified the need for a technology environment to make thinking visible, promote discussions, and support international participants engaged in exploring local issues and contexts.

Outlining design elements. Building on our theoretical framework, we began to delineate the forms of technology, materials, and activities that were needed in the design, as well as the survey instruments and communications modes. A website would be needed to support design activities and curation of resources, as well as social networks. Some form of shared document editing, and design templates would be needed for creating curriculum projects. The curriculum could span multiple iterations of design and enactment, such that designs should be versioned, to support derivative use by others. A workshop model was advanced, including theme groups and synchronous and asynchronous modes of interaction.

Phase 2 - Initial designs

Critical Action Pedagogical Framework. We produced the initial version of a pedagogical framework for Critical Action curriculum design, comprising five dimensions: (1) *Knowledge:* How does your design provide opportunities for students to build their understanding of the issue and advance on some ideas?*; (2) Criticality:* How does your design provide opportunities for students to develop a critical perspective of the problem they are exploring and the social structures that might constrain or leverage their actions? (3) *Action:* How does your design help students to move from understanding to acting on the issue? (4) *Individual*: How does your design help students to reflect on their potential unique contributions to this issue, and develop a sense of direction in schooling and career? (5) *Community*: How does your design help students to organize and coordinate their skills, perspectives, and experiences within a community of peers?

Workshop design. We developed a 5-week workshop model, built around the five dimensions of the pedagogical framework, and supported by a website with discussion areas, shared resources, and design templates. Week 1 (Introductions and orientation) introduced the framework and focused on its first dimension (Knowledge). Participants curated resources and strategies, and developed ideas for lesson designs. Week 2 (Curriculum, Pedagogy and Peer Community) engaged teachers in discussions about Critical Pedagogy and design strategies. Week 3 (Designing with a critical eye) focused on Criticality; Weeks 4 (The critical designer's toolbox) and 5 (Teaching practices, reflections and professional communities) progressed through the framework and focused on helping teachers advance their designs and engage in peer review.

Phase 3 - Outcomes and evaluation of initial designs

Participants. Overall, 60 participants signed up to take part in the CALE summer workshop, coming from Minas Gerais (Brazil), Alberta, Quebec, and Ontario (Canada), Bogota and Cali (Colombia), and California (USA). From the total participants in the workshop, 52 consented in participating in the research, and 47 filled out the pre-survey and shared both their past experiences and expectations of the workshop. Our research participants included 3 school administrators, 8 higher-ed instructors, 2 instructional designers and 39 K-12 teachers teaching a wide range of subjects. 25-45 teachers participated in the weekly Zoom meetings.

Workshop outcomes. 8 discussion topics were built upon with 170 different notes in the asynchronous online community discussions. Overall, 10 lesson designs were created by 11 design teams during the 5-week period. Participants worked in 4 different theme groups negotiated during the first synchronous meeting session: Science, Social Justice, Elementary and Higher Education. All four themes saw at least a medium to high level of activity in three coded dimensions: Peer exchange, Sharing of tools and resources, and use of Critical Action elements. During the final synchronous session, all teams shared their designs with the community, and all 28 participants in that meeting expressed interest in continuing within the CALE community.

Community dynamics. We relied on Knowledge Building principles throughout the workshop to support the collective advancement of community knowledge. Every design team received some peer feedback from a different team. On the final day of the workshop, a high school teacher in practice who had designed a "Science at Home" lesson plan stated: "I would not have been able to think of this goal without the CALE group. Having such passionate people come together [...] makes you change your mind and be curious again."

Discussion

After concluding the workshop, we entered Phase 4 of our DBR—Reflections and Updates to Design Principles. This phase generated three main outcomes: (1) a series of modifications to our pedagogical framework; (2) identification of new features to be added to our technology; and (3) the definition of a model for expanding CALE community to a wider international audience

Improvements to the pedagogical framework

To provide improved support for Critical Action learning designs, we modified the framework to include six components—adding an element of "Global" and organizing according to two axes. The first "vertical" axis includes components that move the community increasingly "deeper" towards action. The second "horizontal" axis increasingly broadens the scope of Critical Action from the individual, to the community, to the whole globe:

Vertical axis (depth): (*1) Knowledge.* Critical Action demands a comprehensive understanding of the issue being addressed. This goes beyond helping students acquire knowledge within a domain, to help them develop abilities to acquire, assess, and build new knowledge. (*2) Criticality.* The process of social transformation implies a value judgment on the issue in hand, and a critical analysis of forces and structures in play that might constrain or empower transformative action. (*3) Action.* A Critical Action curriculum recognizes students' potential as transformative agents, contributing to shift their perspective towards socio-environmental issues from "that's just the way things are" to "that's a problem that I can act upon."

Horizontal axis (scope): *(4) Individual.* Students must have opportunities to explore their intersections with the issue, helping each student create personal meaning and purpose in learning and develop a sense of direction. (*5) Community.* Students must be able to coordinate their individual work and collaborate as a community. (*6) Globe.* Socio-environmental problems transcend borders. Students must comprehend the diverse regional contexts, and how their actions interconnect with other local or global initiatives.

New technology features and future events

We identified two important features that will be implemented in future versions of our technology environment: "Projects" and "Exchange". The Projects area will allow participants to create short descriptions of their intended designs to attract possible collaborators and serve as a project management environment to facilitate the definition and tracking of goals, tasks, deadlines, etc. The Exchange area will allow participants to submit completed designs of lesson plans, resources, and enactments. These materials will then be available to other participants to create copies that can be edited, modified, or adapted to different contexts. Finally, the result of our workshop will inform the design of a series of events to establish CALE cohorts in different countries with the intention to move towards the establishment of a fully open global community. For this purpose, workshops will be conducted in India, Brazil, and Tanzania during the first semester of 2021, and a MOOC will be offered in Summer 2021.

Expansive Framing of Engagement Survey for Online Learners: A Situative Alternative to the Community of Inquiry Survey

Daniel T. Hickey, Tripp Harris, Grant T. Chartrand
dthickey@iu.edu, triharr@iu.edu, gchartra@iu.edu
Indiana University

Abstract: *Expansive framing* is a situative instructional perspective that (a) pushes students to make connections with people, places, topics, and times beyond the course, (b) positions students as authors (rather than consumers) of disciplinary knowledge, and (c) holds students accountable to disciplinary discourse. A new survey of perceived expansive framing was completed by 6,452 fully online students as experimental items within the larger National Survey of Student Engagement (NSSE). Exploratory factor analysis uncovered five of the six intended factors in our 16-item survey and the internal consistency of the six scales ranged from 0.77 to 0.86. Significantly, one of our scales (*Outside Places*) was more highly correlated with the NSSE *Perceived Learning* scale (0.56) than any of the NSSE scales. Pending confirmatory factor analysis, we hope the survey will be more predictive of actual learning outcomes than the popular socio-constructivist *Community of Inquiry* survey or the atheoretical NSSE survey.

This study concerns a new survey of student engagement that is based on situative theories of learning (Greeno, 1998). We contend that the design principles for "expansive framing" of learning that emerged in the work of Randi Engle (1965-2012) are among the most useful to emerge from situative theory. These principles suggest learners "problematize" learning from their own perspective by framing their engagement using people, places, topics and times from outside of the course. This positions learners as authors (rather than consumers) of knowledge participating in a larger intellectual conversation while holding them accountable to disciplinary discourses. Expansive framing is proposed to result in *generative* school learning that transfers widely and broadly. This paper first summarizes the roots of these design principles and our own efforts to use them to create engaging online courses. We then describe the socio-constructivist *Community of Inquiry* (CoI) framework and survey that is widely used in online education. After reviewing our concerns and evidence that CoI scores are unrelated to learning outcomes, we describe our new Expansive Framing of Engagement (EFE) survey and our initial efforts to validate it with responses from 6,452 fully online college students alongside the National Survey of Student Engagement (NSSE).

Productive disciplinary engagement

Expansive framing is rooted in Engle and Conant's (2002) introduction of *productive disciplinary engagement* (PDE) to explain a particularly compelling extended discussion that was recorded in a 5th-grade environmental science classroom. Engle and Conant's analyses were distinctive because they used situative theories of cognition (i.e., Greeno, 1998). Most prior characterizations of student engagement (i.e., in the processes of learning) focused on cognitive associations and thinking processes. In contrast, PDE characterized engagement fundamentally in terms of *discourse*. While this engagement is most obvious in classroom discussions, it can also take place as students interact independently with educational resources. From a PDE perspective, engagement means that students are making substantive contributions to discussions, coordinating their contributions with those of others, attending to others, demonstrating passion or emotion, staying engaged for long periods of time, and spontaneously re-engaging. Regardless of its form, PDE refers to engagement that concerns the *discipline* at hand.

Engle and Conant concluded that there were four "guiding principles" that had caused the PDE they documented. The first principle was *problematizing content*. This principle suggests that educators "should encourage students' questions, proposals, challenges, and other intellectual contributions, rather than expecting that students should simply assimilate facts, procedures, and other 'answers'" (p. 404). The second principle for fostering PDE is *giving students authority*. This is about "students having an active role, or *agency*, in defining, addressing, and resolving such problems" (p. 404). The third PDE principle is *holding students accountable to others and to disciplinary norms*. This means that "the teacher and other members of the learning community foster students' responsibility for ensuring that their intellectual work is responsive to content and practices established by intellectual stakeholders inside and outside of their immediate learning environment, as well as to disciplinary norms" (p. 405). The fourth PDE principle, *providing relevant resources*, reminds educators that students need time and resources to accomplish the goals of the first three principles, and warns that the quest for "authenticity" may lead to disciplinary resources that are too advanced to be used productively by intended students. Arguably, the PDE principles are among the most useful and used instructional frameworks to emerge from situative theories. Engle's (2012) retrospective review identified fourteen other widely cited efforts to reform mathematics or science instruction (many of which occurred before 2002) that had been described by others (i.e., not Engle) as being consistent with the PDE framework.

Expansive framing

The design principles for expansive framing emerged across several studies that moved PDE into the study of *transfer* and the search for generative school learning. This includes Engle's (2006) further analysis of the data from Engle & Conant (2002), the quasi-experimental tutoring studies in Engle and Faux (2006) and Engle et al. (2011), and the extended program of secondary biology research reported in Zheng et al. (2011/in revision). All of these studies pushed learners to frame their learning expansively by (a) finding connections with *settings* (*times*, *places*, and *participants*) and *topics* beyond the learning environment, and (b) positioning learners as authors (rather than consumers) of disciplinary knowledge who are participating in a broader intellectual conversation that extends over time.

The insights across this program of research were summarized in Engle et al. (2012), which presented five explanations of why expansive framing should promote transfer. These included *creating more "intercontextuality" between settings during learning*. Practically speaking, this means that it is crucial for teachers to help students make connections between the learning context and potential transfer contexts. The second closely related explanation is that students will be *more likely to recognize the relevance* of the learned content in the transfer context. The third is that students should *transfer in more of their prior knowledge* because they see the relevance of the prior knowledge and because that knowledge might be uniquely useful for framing and therefore socially desirable. The fourth explanation is that positioning students as authors is likely to *foster accountability to content* which engenders confidence in using that knowledge in potential transfer contexts. The closely related fifth explanation is that positioning students as authors should lead them to *position themselves as authors in transfer settings* independent of the transfer content. In other words, multiple experiences authoring knowledge should result general disposition toward authorship in all settings. The paper provided detailed examples from multiple prior studies for each of these five explanations and went on to consider the potential interactions between the explanations.

While not as widely taken up as PDE, a review by Hickey et al. (2021) identified several promising efforts by others to use expansive framing to support generative learning. This includes our own efforts to use expansive framing to foster PDE in a wide range of online courses, including secondary, undergraduate, graduate, professional, and conventional, open, self-paced courses (e g., Hickey et al., 2017, 2020). Beyond this work, PDE and expansive framing have yet to be taken up widely in online education and computer-supported contexts (but see e.g., Sinha et al. 2015; Fasso & Knight, 2015; Damşa, 2014; Mendelson, 2010). This is surprising because framing seems particularly important in online courses, where curricula must be developed in advance and instructors cannot frame content "on-the-fly" in classroom discussions. This is presumably due in part to the dominance of didactic/expository approaches (as in most MOOCs) and socio-constructivist approaches (embodied in CoI discussed below) and the tensions between them. This situation is likely further due to the emergence of "connectivist" theories of digital learning (Siemens, 2005) that capture some (but we believe) not all of the aims of expansive framing.

The Community of Inquiry framework and survey

Our secondary purpose is creating an alternative to the popular *Community of Inquiry* (CoI) framework and survey that are widely used in online learning research. Consistent with modern socio-constructivist learning theory, Garrison, Anderson, and Archer (1999) characterize the ideal educational experience as "a collaborative communication process for the purpose of constructing worthwhile and meaningful knowledge" (p. 92). CoI is organized around three aspects of "presence." These include *social presence*, *cognitive presence*, and *teaching presence*. The factor structure of the COI survey has been validated (Garrison et al., 2004); and it has been used in over 1,500 empirical studies of online learning (Kineshanko, 2016).

Our concern is in part that the CoI survey seems likely to encourage relatively bounded framing of course contexts. This is because most of the 34 CoI items define presence *within the context of activities and courses themselves*. Just two of the cognitive presence items appear to capture perceptions of anything remotely related to expansive framing. From our perspective, this explains the lack of evidence that CoI scores are related to actual learning outcomes (not just *perceived* learning outcomes). Rourke and Kanuka (2009) reviewed 48 empirical studies of CoI published between 2000 and 2008, and they concluded that only 5 studies measured perceived learning and that none measured actual learning. More recently, Maddrell et al. (2017) found no relationship between the three CoI presences and instructor-assessed learning outcomes.

A practical concern is that the CoI framework encourages practices like individual student-teacher interactions and complex group projects that may be unnecessary, unmanageable, and/or exhausting. Our own approach to online expansively framing (Hickey et al., 2017; 2020) minimizes private instructor grading and student interaction, maximizes public instructor and peer-to peer interactions, and minimizes group projects. More generally, we believe that the interactions encouraged by the CoI framework are partly responsible for the workload and instructor burnout associated with high-quality online courses (e.g., Fox & MacKeogh, 2003; Shea et al., 2010).

With a small internal grant, our original goal was creating an Expansive Framing of Engagement survey and administering it alongside the CoI survey in several large undergraduate online STEM classes that included a high-quality learning outcome assessment. We expected that some of the EFE scales would be highly correlated with those learning outcomes and that all of our scales would be more highly correlated than any of the CoI presences. However, we were unexpectedly presented with an opportunity to administer our new EFE survey items as experimental items to at least 6,000 fully online college students who were also completing the 170 items on the long-running National Survey of Student Engagement (NSSE) administered by the Indiana University Center for Postsecondary Research.

Method

Drawing on Zheng, Engle, and Meyer (2011/in revision), 16 items were drafted to create six scales: *Time:Past*, *Time:Future*, *Other Places*, *Other Topics*, *Roles:Authoring*, and *Roles:Accountability*. Thus, one of the Other Places items asked, "During the current school year, about how often have you ... made connections in a course with settings outside of that course?" ("very often," "often," "sometimes," "never"). Draft items were revised in three cognitive interviews and reviews by NSSE experts; items were deleted to meet a 16-item limit on experimental items, resulting in two to three items per scale.

The 16 EFE survey items were completed by 6,452 fully online college students alongside 170 other NSSE items in 2019. An exploratory factor analysis (EFA) was carried out with odd-numbered participants. The correlations between six EFE scales and other NSSE measures of perceived engagement were explored, with a focus on the *Perceived Learning Gains* NSSE scale.

Results

The EFA showed that the hypothesized factors were indeed present in the data, with the exception of Time:Future and Other Places collapsing into a single factor. This exception made sense in retrospect, because any activity outside of a course necessarily takes place at a different time. Nonetheless, the original six-factor model yielded an acceptable fit with $CLI = 0.944$, $TLI = 0.925$, and $RMSE = 0.064$. Each of the six scales demonstrated reasonable internal consistency (alphas 0.77 to 0.87) and the scale intercorrelations ranged from $r = 0.81$ (Time:Future and Other Places) to $r = 0.42$ (Time:Future and Roles:Authoring). Most importantly, the Roles:Authoring and Roles:Accountability scales (which theoretically reflected the result of the of the other four perceived aspects of engagement) demonstrated acceptably low correlations with the other four scales (< 0.56), though we acknowledge that correlations were attenuated by the lower reliabilities of the two Roles scales. Notably, scores on the EFE Other Places scale were more highly correlated ($r = 0.56$) with the NSSE Perceived Learning Gains scale than any of the ten NSSE perceived engagement scales (though NSSE *Supportive Environment* was $r = 0.55$).

Conclusions and next steps

These results are promising. Our intended factor structure was mostly confirmed, and the scales were sufficiently reliable. Our next step is conducting a confirmatory factor analysis with the existing 16 items. We will then add one item to each of the two 2-item scales, resulting in a 19-item scale. We will also revise the existing items to (a) increase divergence between Other Places and Time:Future and between Other Places and Other Topics and (b) increase the reliability of the crucial Roles:Authoring and Roles:Accountability scales. Consistent with our original goals, we will then administer the revised EFE, the CoI survey, and one or more of the NSSE engagement scales to students in one or more large general education STEM course that includes outcome measures that estimate likely transfer to subsequent educational, professional, and personal settings.

Abstract: We examine how individuals from non-dominant communities and very young children engage with others in ways that affirm their educational dignity—"the multifaceted sense of a person's value generated via meaningful participation in substantive intra- and inter-personal learning experiences that recognize and cultivate one's mind, humanity, and potential" (Espinoza et al., 2020, p. 19). We analyze dignity through the lens of agency and affect to explore interactions between an autistic child playing with a family friend, Indigenous families on forest walks, young people's use of media for affective and sociopolitical action., and a young child recruiting adults to engage in an occasioned knowledge exploration practice. Through pairs of junior Learning Scientist with experts from child development, cultural psychology, anthropology, and linguistic anthropology, we articulate how sharing agency and centering affect can support new possibilities for dignity affirming learning contexts.

Symposium overview

Learners conceptualized as "normal" receive vastly different treatment than those seen as abnormal, outside the norm, or even defined as what they are not-yet (e.g., not-yet adults, Annamma et al., 2013; Goodwin, 1990). The developmental trajectories of White, middle-class neurotypical older children are used as a marker for normality. These trajectories become set-points leading to the categorization of many youth and families from non-dominant communities and neurodivergent learners as deficient or less than "normal" (Annamma et al., 2013; Rogoff, 2003). Young children who are often viewed as not-yet fully developed can also be categorized as less than fully human (Canella, 1999). These deficit perspectives operate at the intersections of identities and differentially lead to lower expectations for learning, restricted learning opportunities, and we fear reduced opportunities for dignity affirming experiences in learning contexts. Although deficit perspectives are leveraged against youth of color is different is critical ways from those leveraged against neurodivergent persons (Annamma et al., 2013) or young children, scholars are increasingly identifying patterns in how repertoires of practice for communicating, attending and observing, resisting and transforming, and inquiring across diverse communities co-constitute dignity-affirming learning contexts that expand and transform conceptualizations of typical developmental pathways.

We seek to spark conversation about how particular populations are/aren't positioned with dignity in consequential learning contexts through analysis of everyday activity. To do so, we present a framework addressing the need to attend to agency and affect when seeking to understand dignity-affirming learning contexts. The overview then provides a brief description of symposium organization. We then present four sets of junior-senior scholar-pairs as they engage together in analysis of junior scholars' data through the lens of senior scholars' work from diverse disciplinary perspectives (i.e. child development, cultural psychology, anthropology).

Conceptual framework: Affect and agency in dignity affirming learning contexts

We position those often framed as not-fully- or not-yet-human as multi-faceted beings engaged in making sense of the fullness of their humanity and their worlds. This at once feels like an obvious call and a radical push against oppressive conceptualizations of limited human capacity for those at the margins and not-yet-grown. It is a necessary move to understand the diversity of human learning (Gutiérrez & Rogoff, 2003; Philip et al., 2018).

We take up Espinoza, Vossoughi, Rose, and Poza's (2020) definition of educational dignity as "the multifaceted sense of a person's value generated via meaningful participation in substantive intra- and inter-personal learning experiences that recognize and cultivate one's mind, humanity, and potential" (p. 19). This definition recognizes a person's value is inherent in the person, but that such dignity is affirmed and fully realized only within social interaction. Thus, it is not enough to state someone has dignity; it must be enacted and affirmed. This framing of dignity is positioned within a sociocultural lens on everyday learning, being, and doing in the world. This lens on life recognizes that abstract ideas like dignity, agency, and affect are brought into being through persons-in-interaction (Blumer, 1954). Just as "dignity relies on social action for its manifestation" (Espinoza, 2020, p. 19), agency is also a collaborative endeavor (Damşa et al., 2010; Gresalfi et al., 2009), and affective stances help create the social order of interaction that affirms dignity (Goodwin & Cekaite, 2018). Thus, each scholar-pair examines these sociocultural understandings of persons-in-interaction in their analyses.

Our selection of dignity, agency, and affect is purposeful. Returning to our central construct of educational dignity, we recognize vulnerability between participants creates "emotional and cognitive conditions" that facilitate "sharing of histories and testing of ideas" (Espinoza et al., 2020, p. 14) in learning interactions. Each scholar pair examines how particular affective states (e.g., playfulness, wondering, love, curiosity) create contexts for learning, drawing on affect as central to learning as an emerging theme in Learning Sciences research (e.g., Jaber & Hammer, 2016). Agency as an interactional accomplishment, a core Learning Sciences conceptualization of agency in learning contexts (e.g., Damşa et al., 2010; Gresalfi et al., 2009), sheds light on processes supporting engagement in particular ways of knowing as well as their inquiries about knowledge itself. By this we mean that we wish to understand how young people already take initiative to create learning contexts (e.g., de León, 2015) and how learning designs can further position those who historically occupy social positions deemed to have less power (e.g., nonverbal neurodivergent individuals, Indigenous families, youth of color, young children) as agentic co-creators attending to "pressing philosophic concerns" (Espinoza et al., 2020, p. 18). In doing so, we hope to better understand how sharing agency may lead towards imagining new possibilities and transforming existing structures to achieve those possibilities (see Calabrese Barton & Tan, 2010). Taken together, we believe this framework will allow us to better understand how participants-in-interaction can respond with care—attending to another to enhance their wellbeing (Goodwin & Cekaite, 2018)—through dignity affirming interactions.

Format

We propose a non-traditional format based on a successful special session on the socio-political and ethical horizons of the Learning Sciences (Vakil et al., 2020) that was designed to support learning with and from junior and senior scholars. Scholars were matched with the intent of shedding light on the conceptual and methodological focus of junior scholars through the extensive bodies of work from senior scholars (Figure 1).

Chen	draws on	Cekaite's work to	explore how learning ecologies that uphold the communicative agency of autistic individuals occur through the creation of flexible sociomaterial spaces
Marin	draws on	Rogoff's work to	examine the role of attention and observation as Indigenous families with young children take walks through forest preserves together
Cortez	draws on	de León's work to	examine the ways non-dominant populations develop agentic and political stances as they leverage digital technology in their everyday lives
Keifert	draws on	Goodwin's work to	examine how adults respond to a child's spontaneous curiosity by following his lead to affirm his family occasioned knowledge exploration practice

Figure 1. Junior-Senior Scholar-Pairs and their Analytical Focus

Following a brief introduction (3min), junior-senior scholar pairs will present data from junior scholars' work and analysis based on foundational ideas from senior scholars' theory with a lens on dignity, affect, and agency (10min each). Scholar-pairs will then respond to prompts from our discussant (5min). Following these cycles of junior/senior scholar pairs (total 60min), our discussants, Drs. Kris Gutiérrez and Shiri Vossoughi will provide reflections (12min) before guiding our discussion with all attendees (15min). These pairings and the process for reflection provide avenues to expand disciplinary boundaries of LS and contribute centering educational dignity.

Significance

There continues to be a need to draw on research of interactions and learning in ways that support "humanizing creativity" (Espinoza et al., 2020, p. 9) requiring the continued development of research approaches that center diversity (Medin et al., 2017). This includes deepening understandings of how marginalized young people and those construed as not-yet-developed navigate the multiple communities in which they situate themselves. The analyses shared in this symposium as well as the scholarly pairings will support dialogue about how people collaborate in meaningful ways in their own learning, being, and doing in the world. In so doing, this work contributes to understanding the "diversity of human cognition and development beyond participants, methods, and purposes" rooted in White-dominant norms (Philip et al., 2018, 83). We present now our four scholar-pairs: Rachel Chen & Asta Cekaite, Ananda Marin & Barbara Rogoff, Arturo Cortez & Lourdes de León, and Danielle Keifert & Marjorie Harness Goodwin.

The transformative role of a stimming object in autistic interaction

Rachel Chen and Asta Cekaite

Autistic individuals form close, affective, sensorial relationships with objects (Conn, 2015). Many of these objects are involved in the enactment of repetitive movement (e.g. tapping, rocking, flapping), a category of behaviors that diagnostically defines Autism (DSM-5, 2013), otherwise termed *stimming* by the Autistic community (Kapp, 2013). Whereas autistic object usage is traditionally conceived as rigid and inflexible, especially if involved in stimming (Leekam, 2011), the prevalence of objects in children's sensory play suggests they may be used more creatively than previously assumed. The propensity to repeat and innovate is prevalent in neurotypical children's interactions, through playful recyclings of repetitive language (Cekaite, 2004) or locomotor imitation and elaboration (Hoey et al., 2018) as an affective context for play. Embracing the significance of objects in autistic interaction may reveal inventiveness that may otherwise be missed. This line of work has implications for Special Education and the creation of flexible sociomaterial environments that reveal, and thus celebrate the communicative agency of the Autistic student.

Background and methodology

The video data selected for analysis is of Matt, a 6-year-old non-speaking boy on the Autism spectrum, and his interaction with Ben, a 17-year-old family friend. The data come from a video ethnography corpus of naturally-occurring interactions between Autistic children and their families, educators, and friends. The object of focus in this extract is a plastic hair comb, which at the time of data collection, was Matt's most frequently held object. Due to its flat surface and its ergonomic size for Matt's hold, it became an object for his repetitive tapping (Figures 2-5). Prior to the start of the recording, Matt's sister finds his comb lying on the floor. She picks it up just before Matt runs towards it, and playfully passes it to Ben. This analysis focuses on the evolving role of the comb as the interaction unfolds.

Data analysis

Establishing new understandings of objects as something other than its original function requires complex interactional work (Cobb-Moore, 2010). Ben first transforms the function of the comb into the object of play by dangling it in front of Matt's face (Lines 21 and 26), lifting it beyond Matt's reach just as Matt attempts to grab it (Lines 23-25, 28-29). As the interaction unfolds, the comb's function is continuously transformed, and the emerging game between both participants traverses through different play genres. After Matt's many unsuccessful attempts to grasp the comb, Matt produces a surprising social action: He grabs Ben's wrist and brings the comb to his hair, pretending to enjoy having his hair combed. In a swift move, Matt raises his left hand and grabs the comb from Ben's hand, bursting into laughter when he is successful in this endeavor.

```
21  MATT       [d'wan']=
22        =((eyes on comb))
23         ((snatches comb))=
24  BEN   =|((brings it away))
25         |ooh↑.
26  MATT  H[h. hhhhh.
27  SIS    [hh. Hhhhh.
28  MATT  |°hoo°
29        |((tries to snatch comb))
30  BEN   M|m-ho:↑-|no:.
31          |((raises comb away))
                   |((lowers comb))
```

Figure 2. Matt and Ben interact together with the comb.

Figure 3. Matt pretends to comb hair.

Figure 4. Matt grabs the comb.

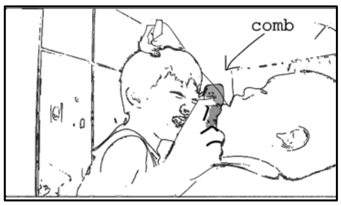

Figure 5. Matt laughs, lowering his hand.

From the object of a stim, to the object of a game, Matt uses the original function of the comb—for one's hair—as a means to 'win' the comb back from Ben. The transformative role of the comb reveals Matt's ability to be flexible and creative with his favorite object. By enacting the first transformation of the comb into the object of a game, and by through his interaction with Matt, Ben is creating a learning ecology where Matt and Ben can come into intercorporeal attunement, affective embrace, and creative transformation. This short analysis shows how a dignity-affirming learning context is constituted through affective (playful) collaborative transformations of the object-centered activities, spontaneously occurring in mundane interaction.

The multiplicities of dignity-affirming interactions: Accounting for multispecies ensembles as a context for the coordination of attention and observation

Ananda Marin and Barbara Rogoff

We bring the framework of dignity-affirming learning as meaningful participation in interaction that cultivates a person's value into conversation with our shared interest in learning through the coordination of attention and observation. We also extend the framework of dignity-affirming leaning to consider the role of more-than-human subjects in meaningful participation. Our individual research programs unite around a collective interest in foregrounding diversity in the cultural processes of learning. Over the last three decades, Barbara Rogoff and colleagues have iteratively articulated Learning by Observing and Pitching In to family and community endeavors, or LOPI, as a multifaceted approach to learning. This approach is common in Indigenous communities in the Americas (Rogoff, 2014). Three facets of LOPI are particularly germane to our consideration of the interactional accomplishment of dignity: (a) social organization of endeavors through collaborative, flexible ensembles (facet 3), (b) wide, keen attention and contribution to events (facet 5), and (c) communication based on coordination through a shared reference in collective endeavors (Rogoff, 2014). Marin (2020), building with this approach and Indigenous educational philosophies (Cajete, 2000; Simpson, 2011) has examined Indigenous families' forest walks as a context for understanding learning through *the coordination of attention and observation on the move.*

In this paper we ask: *how do young children along with adults coordinate attention and observation while on the move as they engage in flexible ensembles with more-than-human kin?* What patterns do we notice with engagement and how might this expand our understandings of LOPI? To ground our discussion of these questions we first review the scholarship of Rogoff and colleagues who have consistently found cultural differences in the organization of attention and collaboration. For example, in one study with Navajo children, López et al. (2012) have shown that when one child took lead and provided instruction for game play other children remained engaged. This finding has been replicated with Mexican-heritage children whose families come from communities with Indigenous history. In contrast, European-American children whose families have extensive history of participating in Western schooling follow a different pattern. For example, when three or more European-American children took part in a task making puzzles or model toys and one child took lead the others tended to go off task with more frequency. Importantly, the tasks which contributed to this body of work were primarily conducted in indoor settings where children were seated. We extend Rogoff's work on cultural patterns in multi-party engagement to further examine how research contexts inform our creation of developmental theory.

When we shift our analytical lens to consider the role of lands/waters in interaction then more-than-human kin as co-participants in ensembles becomes magnified. Moreover, children's engagement in flexible ensembles that include more-than-human kin can look quite different from children's participation and engagement with playing board games. We suggest that in the context of forest walks, staying engaged as people participate in flexible ensembles with more-than-human kin widens the perceptual field and consequently young children use a variety of combinatorial and multimodal formations for coordinating attention and observation. To further explore this work hypothesis, we present a case example from the forest walk of an Odawa (Native American) mom, and her two sons Jason (age 7) and Sam (age 4). They were asked to go on a series of walks, five in total, as a part of a case study on how families coordinate attention and observation as they learn about the natural world. On the family's third walk they made their way into the forest canopy where they noticed trails which Jason declared were made by an animal, setting up an affect stance for wondering together. A few minutes later, Jason says, noticed "fresh tracks." Amazed by the size of the track Jason commented "Ah, there's no such thing as an animal that bigga foot." His mom then asked what made the footprint and Jason responded with "some animal." This interaction highlights the role of affect in learning. Jason's amazement with his observation creates a context for multi-party engagement and collaborative storying of the environment. In this moment a multispecies ensemble is created that includes human and more-than-human kin. As the family moves to find their way, Jason, uses a stick to point out frog prints ("Hey look it, frog prints, these are..."). As he does this, his younger brother Sam orients his body so that he is facing Jason and both look down at the ground (Figure 6A). Jason then reorients and begins walking along the trail again (Figure 6B). Sam who is behind Jason says "I think there's frogs living in here." Sam, then says "I, go" as he bends his knees getting ready to jump. He jumps three times, each time saying "jump" before running ahead of his brother (Figure 6C). Meanwhile, Jason is still making sense of the foot prints. In a low voice, almost as if he is speaking to himself, he exclaims, "And the coyote caught it. Dropped it a couple times. That must be the story of the footprints."

A. B. C.

Figure 6. Images of Jason and Sam's unfolding action from the mother's wearable camera.

Recognizing the agency of more-than-human kin is a common practice among Indigenous communities (Bang & Marin 2015; Cajete, 2000; Kimmerer 2013; Simpson, 2011). In the case presented here we see young Indigenous children recognizing more-than-human kin (i.e., coyotes, frogs) as agents who like them are interacting with lands/waters. At the beginning of the interaction presented Sam and Jason are in a face to face formation that includes land. This formation provides an essential context for the coordination of attention and observation and engagement with the question at hand (who made the tracks?). Once this shared reference is achieved, the formation changes, with Jason and Sam in a tandem formation. This shift could be read as out of sync. Instead, we suggest that this is shift is dignity affirming. Both Sam and Jason explore their relationship to the particularities of the land they are walking. Sam embodies the movements of frog and Jason stories the interaction of frog and coyote. This new formation provides opportunities for both children to maintain their ensemble and participate in ways that support their ability to meaningfully contribute to walking, reading, and storying land. Taking this analytical approach helps to explicate how attention and observation are maintained in ways that include lands/waters and affirm the dignity of young persons in interaction with each other.

Agency, affect, and morality in virtual spaces of nondominant youth: Nuevas Expresiones de Amor y Empatía

Arturo Cortez and Lourdes de León

We extend the notion of dignity-affirming learning contexts to illuminate the development of moral and affective stances in the microlevel processes of non-dominant young people as they engage in everyday usage of digital technology and new media. Drawing on an ecological perspective, we contend that virtual learning environments create opportunities for young people to resist, rearticulate, and transform their cultural repertoires of practice (Gutiérrez & Rogoff, 2003) as they engage in socio-political critique and the micropolitics of affective exchanges in their virtual communities of practice. This engagement is enacted through video game play, romantic textual exchanges, and exchanges in virtual landscapes. In the following, we explore how we take up these examinations in our work and offer considerations for future inquiry.

In the context of social rebellion and global pandemic, digital technology and new media are increasingly leveraged as part of people's everyday practices of civic engagement, opening up "emerging forms of agency" (de León, 2017, p. 463), activism, socio-political critique, and other forms of resistance that can be imagined and enacted in our societies (de Kosnik, 2016; Lizárraga & Cortez, 2019). Online video game play has gained traction as a site of digital activism, especially in opening up new theoretical, methodological, and pedagogical possibilities for studying the ingenuity of young people (Gutiérrez, et al., 2017; Rivero & Gutiérrez, 2019). Mirra and Garcia's (2020) notion of speculative civic literacies highlights the development of "expansive, creative forms of meaning making and communication aimed at radically reorienting the nature and purpose of shared democratic life toward equity, empathy, and justice" (p. 297). Drawing from Mirra and Garcia (2020) and de León's (2017) examinations of digitally mediated practices as consequential for meaningful cultural and linguistic activity, Cortez's study examines the development of *speculative activist stances*—defined as a co-constructed repertoire of resistance practices, leveraged across digital and social media domains, oriented toward organizing new civic futures. Goodwin's (2007) participation frameworks illuminate the epistemic, moral, and affective stances that participants engage in as they develop new digital, social, and imaginary worlds. In particular, this study examines how speculative activist stances were co-constructed and enacted in an online gaming ecology, composed of young people from across the world as they organized a tribute and memorial to George Floyd, organized a protest of the endemic police violence against Black communities, while they played *Grand Theft Auto V*. Through the analysis of the microprocesses of multiple types of interactions (Figure 7: game moves, online streamed chat, and talk among the players) in video game play, this study argues that speculative activist stances illustrate how young people contend with, complicate, and rupture mainstream notions of activism. Here, young people are co-constructing new types of activist practices that bring together notions of care, love, solidarity, and aggression as they challenge hegemonic power structures in their microlevel practices. This study offers implications for the design of learning environments that could leverage video game play as a central site for the development of sociopolitical action and critique.

Figure 7. Screenshots of *GTA V*. (a) Funeral of George Floyd. (b) Protest at Police Station. (c) Memorial for George Floyd; cars lined up in "GF".

In a parallel fashion, de León examines romantic texting and ethnopolitical virtual landscapes among Mayan Tzotzil youth as discursive practices that have their effect in a contentious field of social activity, indexing micro-processes that contribute to the reconfiguration of new subjectivities, feelings, and moralities (Ahearn 2001). She argues that digital communication has not only produced new forms of courtship, affect, and ethnopolitics but has also fostered new technological, linguistic, and literacy skills that have significantly changed repertoires of identity (Kroskrity 2000), voice, and imagined possibility among Mayan youth (de León, 2017).

Both Cortez's and de León's projects reveal youth's ingenuity in crafting new social personas in the multimodal deployment of affectivities and moralities that enable new alignments, visions, and practices for social futures. We consider these virtual communities of practice as a potential site to understand how nondominant youth rearticulate socio-political critique and cultural repertoires of practice.

Cultivating educational dignity by following children's serendipitous curiosity

Danielle Keifert and Marjorie Harness Goodwin

How is educational dignity cultivated by following children's curiosity? Curiosity is a powerful affect central to being human. Occasioned knowledge exploration (OKE)—moments when people "extemporaneously connect new knowledge to existing knowledge in collaborative endeavors" (Goodwin, 2007, p. 97)—and family practices (Keifert, 2015) shed light on explorations of "fanciful worlds as well as more mundane actual situations" (Goodwin & Cekaite, 2018, p. 206). We wonder how noticing family OKE practices allows teachers to follow children's curiosity in school. Figure 8 summarizes two of Charlie's (2y10m) experiences recruiting adults to explore stories about which he was curious by animating—giving voice to (Goffman, 1979)—to characters.

C: **Did you talk about um Up come?**
M: And then Up started? An what part of Up do you want to talk about?
C: **An' an the dogs-...why did he eat his dinner?** *Charlie touching Mommy's arm.*
M: Oh, the dogs were eating the little kid's dinner? The little kid had a hot dog, huh.
M: n' you remember when you go to see Grandpa and Grandma sometimes.
C: Yeah.
M: And what's their dog's name? *Mommy tilts her head towards Charlie.*
C: Gem.
D: And what did Gem do to you once?
M: Does Gem every eat your food? *Mommy squints and makes a little face at Charlie.*
C: Yeah.
M: You have to be careful and be up high, huh.
C: Why?
M: Because Gem sees that food that thinks boy am I hungry, and boy does Charlie's dinner look good. And then she goes amnom nom nomnomnomnom and she eats it all up. *Mommy makes chomping gesture with her hand for each "nom".*
C: Why I don't like that. ((Charlie shakes his head no))
M: I know you don't like that. So you have to keep it away from her, huh...
M: But the kid in the movie doesn't know that an' so he doesn't keep his food away. And there's a::ll of those dogs in that house. And they all just keep coming up and saying, 'Hmm that looks good. I think I'll take a bite. Ohmp.' *Mommy moves her head and takes an exagerated bit of air with each "Ohmp."* And another one comes up and goes, 'Hmm, that looks look. I think I'll take a bite o that. Ohmp." And before you know it. It's all gone. They've eaten his whole dinner.
C: But, a-
M: And he's going 'Hey. Eah! Eah! Where's my food going?' And then his food's all gone.
C: Wha- is he hungry?
M: He's probably still hungry, huh.

TM: They made him king of a::ll the wild htings. And now cried Max, LET THE WILD RUMPUS START!
TM: There they are. Some wild rumpusing.
C: **Where's the little kid?**
TM: Max. Right there. ((pointing)) Here's some more wild rumpus action.
C: **Are they at ho- da home?**
TM: They're where the wild things live. And here they're having a wild rumpus parade.
C: I went to the parade.
TM: Or a procession. I know. We sat together.
C: Why did you see me at the parade?
TM: Cause...you came over and hang out with me.
C: We had french fries.
TM: And we had donuts.
C: I ate the little donut.
J: **Did I come an hang out with you?**
TM: You didn't. It was just Charlie.
TM: ((reading)) Now STOP! Max said and sent the wildlings off to bed without their supper.

Bold = Children's Questions

Figure 8. Abbreviated talk. Left Mommy (M) and Charlie (C). Right Teacher Matt (TM) + Charlie (C).

At home, Mommy responded to Charlie's bid to explore Up (left) by shifting to exploring a prior experience through animating Gem. Charlie responded by animating his past-self before they repeated the pattern of Mommy animating the dogs in Up and Charlie animating the boy. In both stories, Charlie animated his past self, acting as an author in co-story telling. Charlie's bid for engaging in this family OKE of *exploring narratives together* was received positively by Teacher Matt two days later in his classroom (right). Charlie's questions were attended to, leading to explanations of Where the Wild Things Are, and giving Charlie the chance to connect to a prior experience. Both Charlie and Teacher Matt animated their past-selves. It was likely easy for Teacher Matt to follow Charlie's lead because Charlie's form of OKE was similar to literacy practices in the classroom. This is not always the case. A child the same age in Charlie's classroom, Catherine, was repeatedly rejected when she tried to engage in her family OKE practice (Keifert, 2015). In that case, Catherine's playful tone asking "What if the crickets got out [of the terrarium]?" was received with a concerned tone indicating that shouldn't happen for the crickets' safety. Catherine was not supported to engage in her OKE practice. Catherine's agency to pursue her curiosity through engaging in a familiar inquiry practice with her teacher closed down by her teacher.

The more adults look, the more opportunities they have to see children's brilliance. What happens when teachers give children agency to lead when they are curious? Charlie was positioned with agency to shape meaningful participation—he was positioned with educational dignity (Espinoza et al., 2020). Charlie's experience demonstrates affirming dignity for young children often construed as not capable (Cannella, 1999). Likely the more different a form of OKE is from those forms common to a context the more challenging following a child's lead may be (e.g., Heath, 1983). Yet, learning to recognize children's practices as relevant and attending to shared affective engagement is necessary. The centrality of curiosity to human experience demands educators learn to follow children's serendipitous curiosity to affirm educational dignity.

Abstract: Building on Vea's (2000b) emotional configurations perspective, this symposium examines emotion and learning across a range of environments representing science education and explicitly politicized contexts. An emotional configurations perspective denaturalizes supposedly individual, internal, and discrete emotion states and instead foregrounds the ways that participants in social activity coordinate relationships between feeling, sense-making, and practice. In these four studies, we argue that emotionality should be more centrally interrogated in learning sciences research because it shapes what is learned and how learning unfolds, and itself becomes part of learning outcomes. The combined work makes theoretical contributions by interweaving emotion within sociocultural theories of learning and methodological contributions by sharing productive approaches to centering emotion as an object of analysis.

Framing and contribution: Emotion as more than a feeling

Emotion exhibits complex entanglements with thinking, activity, and learning. Building on Vygotsky, for example, Ratner (2000) conceptualized emotions as "thoughtful feelings" (p. 6). Roth (2007) emphasized that emotion serves as a "constituent element" of human activity (p. 45). And yet, the learning sciences have paid relatively little attention to the role emotion plays in learning processes. This symposium uses socioculturally oriented approaches to interrogate the role of emotion in shaping learning and sense-making in school-based and explicitly political out-of-school learning environments. We look across contexts to attend to if and how emotionality is centered in learning settings and what the consequences of explicit attention to—or refusal of—emotion does to shape the sense that is made of feelings and of conceptual cognition by learners and researchers.

As a starting point for our analyses, each paper in the symposium takes an emotional configurations perspective (Vea, 2020b). This perspective denaturalizes supposedly individual, internal, and discrete emotion states and instead foregrounds the ways that participants in social activity coordinate relationships between feeling, sense-making, and practice. Within this perspective, emotions are understood to be situated and grounded within particular social and cultural contexts (Boler, 1999; Zembylas, 2007). Emotion only becomes meaningful in contexts of activity. In this view, emotion is seen as inherently bound up in social practice—both as a form of practice, in the case of emoting and emotional management, and as entangled with other forms of practice. Ways of feeling can support the effective performance of other practices, such as when service workers use emotion to smooth capitalist exchange (Hochschild, 2012). Further, emotion is governed by norms and shaped by ideology and power relations, with implications for the futures that people can imagine and how they organize themselves to make those futures real. We assume that emotion is collaboratively constructed among members of a community, that emotion's meanings are shaped in and through sense-making processes in community, and that the sense that is made of emotion can, and often does, change as part of learning processes. From this perspective then, any learning endeavor will have emotion as a critical component.

Where and when is emotion in learning? Recent learning research shows concern for how affect and emotion support learning more broadly (DeBellis & Goldin, 2006; Ehret & Hollett, 2016; Gupta et al., 2010; Jaber & Hammer, 2016; Nemirovsky, 2011). Some learning researchers have also suggested ways that emotion may figure as part of learning outcomes, such as "affective know-how" (Hollett & Ehret, 2016) or "emotional engagement" (Sakr et al., 2016). Extending these conceptualizations, emotional configurations provide a way of seeing emotion as dynamic and always in process. Vea (2020b) argued that emotion serves in two modes: as a condition or quality of being that drives learning activity and as a learning target in its own right. The two modes can recursively flow into one another over the course of activity. For example, "epistemic affect" (Jaber & Hammer, 2016) and other forms of feeling can drive learning engagement as people attempt to resolve tensions or inconsistencies in phenomena and thinking. In the course of the same activity, educators and other social actors may cultivate ways of feeling in relation to sense-making and practice as part of learning goals. Emotion not only shapes what is learned and how it is learned—but is also itself part of the learning, iteratively re-shaping and resignifying the sense that is made (Vea, 2020b; Curnow & Vea, 2020).

In this symposium, we bring together two strands of developing scholarship. First, we identify emotion as an emergent issue in politically engaged informal learning environments. Vea's work has shown how "guided emotion participation" shaped whether and how animal rights activists became engaged in activist work. Through intentionally organized emotional experiences, activists came to make sense of relationships with nonhuman animals and with eating meat in particular ways, which shaped their political development by generating and giving meaning to strong emotional experiences. Curnow et al. (2020) examined the relationship between anger, snarky humor, and learning in youth climate activism. They argue that humor-infused expressions of anger enabled politicization of young women, as it opened space for grievance construction, problem solving, and community solidarity in ways that had been foreclosed in other spaces. Emotion became a mediating tool for expressing feelings that had gone un-named, and enabled participants to frame their emotions within the lens of feminism and anti-racism, making them politically salient within broader transformations of feminist practice, identity, worldview, and political analysis. Curnow & Vea (2020) also synthesize their respective work to argue that emotion is fundamental to processes of politicization. Additionally, we see a proliferation of work that attends to questions of belonging, trust, solidarity, and intimacy (Teeters & Jurow, 2018; Uttamchandani, 2020; Vakil et al., 2016), which gesture to the importance of felt experience, sense-making, and scale-making that is made possible through those relations. While their work does not explicitly orient to emotionality, it points to opportunities to more fully theorize emotional configurations that make feeling seen, feeling at home, feeling part of something bigger more likely, as it traces the impacts of those feelings (Vea, 2020a).

Second, similar threads are emerging in science education research, where there is increasing focus on emotion in children's, teachers', and scientists' disciplinary pursuits in a discipline often framed as unemotional, rational, and objective (Burbules & Linn, 1991). To larger discussions of how to support and design for science disciplinary practices in school and out of school contexts, there is an emerging understanding that emotions are part of what "instigates and stabilizes disciplinary engagement" in scientific pursuits (Jaber & Hammer, 2016), wherein learning science is intertwined in learning to feel and navigate feelings in new ways. Drawing on sociological studies of science as well as scientists' memoirs, Davidson and colleagues (2020) assert that emotions are "part and parcel" of the experiences of scientists, and should be recognized as integral to the experiences of science learners for children and adults alike. Likewise, this acknowledgement of the importance of emotion in the doing and learning of science may further push the field to consider the ways in which opportunities to learn through and at the level of emotion in science are afforded or constrained to populations who may be otherwise marginalized within the discipline (Bang et al., 2012).

When taken together, this work brings a key question relevant to the learning sciences into focus: When, for whom, how, and to what ends are emotions consequential for learning and research on learning? Each paper engages such considerations of emotionality differently: Curnow attends to how emotion shaped the sense-making process in the RadLab's analytic work, while Vea analyzes the emotional configurations embedded in animal rights activists' commitment to non-violence. Lanouette unpacks children's' emotions in a schoolyard ecology unit, while Davidson, Jaber, & Southerland examine the emotional configurations of scientists, teachers, and students. While we explore widely different contexts, from research spaces to activist contexts to school and after-school programs, across the work we attune to how emotion shapes the sense-making process. We find that emotion is present in all of these spaces, shaping what is learned, how, and by whom, and we find that emotion is almost always pushed aside rather than reckoned with as a mediator or target of learning and collaboration. Across the symposium contributions, we demonstrate the diverse ways emotion is consequential for learning. Taken together, the symposium makes three key contributions to emotion in the learning sciences: (1) it offers a range of theoretical enactments of emotional configurations across a wide range of learning environments, integrating emotional attunement into sociocultural theories of learning; (2) methodologically, it offers productive pathways forward for reckoning with emotion as an object of analysis in all learning environments; and (3) it argues that, across a range of learning environments, attuning to emotions can illuminate heretofore underexplored aspects of the learning process. Authors will present papers for 10 minutes each, followed by commentary by our discussants. Time will be reserved for discussion of how emotion should or could be taken up within the learning sciences, and the consequentiality of emotion for learning ecologies. Questions include: How might the learning sciences analyze emotion? What tools do learning scientists have in our repertoires for analyzing emotion, and how might we do so without reifying emotional practices and meanings? How do our own feelings shape how we read our data, participate as researchers, and engage in analysis and theorizing about learning?

Eating a kilo of chocolate as method: How emotional configurations of analysts shape data analysis and sense-making

Joe Curnow, University of Manitoba

In this paper, I examine the role of emotion in analyzing video data of emotionally charged debates. I argue that the emotional configurations of our research collaborative, the RadLab, were highly salient to our ability to conduct analysis of the significance of emotion in the data we analyzed, while also creating a complicated context for being immersed in the data. The RadLab is composed of activist researchers who were embedded in the Fossil Fuel Divestment campaign at the University of Toronto, and who co-designed and led the analysis of two years of video data. Our participation was both as research participants and analysts, drawing on Participatory Action Research frameworks (Brown & Strega, 2005), and militant ethnography (Scheper-Hughes, 1995). Fossil Free UofT was a student-run campaign aiming to convince the University of Toronto to divest from fossil fuels. From September 2014 to April 2016, Fossil Free UofT met weekly to plan events and coordinate strategy. Meetings lasted two to three hours, with facilitation responsibilities rotating between members. The group included undergraduate, masters, and PhD students. Through analysis of over 15000 minutes of multi camera video data (Derry et al., 2010), we analyzed how some participants came to understand themselves as radical activists. While we have used our content-logging, coding, and analysis in other places to make sense of the learning dynamics of the campaign, here we pause to reflect on the significance of emotion on our analytic process and ask: How do the emotional configurations of analysts matter when we are investigating emotionally messy learning ecologies?

This paper contributes to ongoing work in the learning sciences to analyze when and how emotion shapes learning processes and how learning shapes the felt experience of emotion. While recent work has examined guided emotion participation (Vea, 2020b), the consequences of emotionality for learning in social movements (Curnow & Vea, 2020), and the specific ways that humor, sarcasm, snark, and rage create conditions for politicization (Curnow et al., 2020) and educational intimacy (Uttamchandani, 2020), this work has focused on participant learning. Our work builds from this space, but attends to how our emotionality as analysts (and as participants in the data) shaped how we made sense of and re-experienced the emotion of our data in the analytic process. To do so, we draw on feminist and Indigenous research methodologies which stress relational accountability (Hampton, 1995; Wilson, 2008) and standpoint epistemologies (Collins, 1982; Harding, 2004) alongside theories of emotion and affect (Hochschild, 1979).

We collected video data from weekly meetings, actions, and debriefs during the campaign, and across this data, the meetings became increasingly emotionally intense. Toward the end of data collection, meetings often included yelling, crying, storming out, and other emotional expressions. Participation in the meetings was difficult—as was content logging, coding, and analyzing the data in detail, because of the emotion that it re-generated. As we watched video-data, our team of analysts often ended up feeling extremely upset, with some of our team lying on the floor in despair, while others ate entire kilos of chocolate bars. Rather than assume that scholars enter the data as emotionless and disinvested, we reflect on how our process of sense-making about the learning that unfolded through contentious politics was entangled in reconstructed emotional configurations of the data in a way that was felt during the data collection, as well as the layered sensemaking and feeling that happened in our collaborative data analysis sessions.

This analysis is significant for the learning sciences in a few ways. First, it builds on work around emotion by bringing our methods of analysis into focus and acknowledging that as thinking and feeling people, analysts' experience of emotionality in the analysis process happens and is significant to how we make sense of our data. This is both a methodological intervention and a political intervention, which converges with other work in the learning sciences that has increasingly sought to disavow the notion that objectivity and neutrality are either possible or desirable for our work studying learning contexts (McKinney de Roysten & Sengupta-Irving, 2020). In acknowledging the ways that our emotionality shapes the sense we make of our data, and the way that the sense that is made shapes how we feel about the data, this meta-analysis draws attention to how emotion shapes learning not only in the contexts we analyze, but in the very ways we conduct analysis and make sense of our research data.

Nonviolence past and present: Learning with an emotional technology in transit

Tanner Vea, Pennsylvania State University

Tracing nonviolence's political history from Mohandas Gandhi, through Dr. Martin Luther King, Jr. and the Black Civil Rights Movement in the United States, to contemporary uses in animal rights activism, this paper asks how nonviolence supports particular emotional configurations in activist practice in socially and historically situated ways. Gandhi wrote in his autobiography, “Whereas a good deed should call forth approbation and a wicked deed disapprobation, the doer of the deed, whether good or wicked, always deserves respect or pity as the case may be” (Gandhi, 2012, p. 214). This idea was central to the practice of *ahimsa,* or nonviolence.

Writing about settler colonialism as a set of technologies, la paperson (2017) wrote, “Technologies are trafficked. Technologies generate patterns of social relationships to land. Technologies mutate, and so do these relationships” (p. 5). This paper takes as its starting point the idea that technologies also support the organization of emotional configurations (Vea, 2020b). An emotional configurations perspective treats emotion not as composed of universal states but rather of situated sociocultural phenomena (Lave & Wenger, 1991) embedded in complexes of social practice. Here, I examine nonviolent resistance, an emotional technology with many histories. I contend that nonviolence in fact names a set of relations between feeling, conceptual sense-making, and practice—in other words, an emotional configuration. Yet the patterns of relation that nonviolence generates are not identical across time and space. They mutate according to the particulars of their deployment, but they are always a matter of learning, of taking up particular ways of making meaning about emotion and what it is good for. From whence an emotional technology is trafficked itself becomes part of the relation.

This paper is part of a larger research project on learning in the context of animal rights activism (Vea, 2019, 2020a, 2020b). It presents empirical analysis of ethnographic fieldnotes and interviews (Emerson et al., 2011; Spradley, 1979). Thematic coding resulted in a focus on the social shaping of emotion and emotion’s embeddedness in other forms of activist practice. The activists of Direct Action Everywhere (DxE), an animal rights network of activists based in the San Francisco Bay Area, used nonviolence trainings and narratives about nonviolence as part of their political project. I examine the situated nature of those uses. However, in line with the conference theme, I examine the history of nonviolence as an emotional technology for learning. Historicity becomes part of its meaning, and the contemporary context of use also shapes possibilities for learning and social change.

Nonviolence directs anger away from perpetrators of injustice toward the larger systems of injustice that are understood as the root cause. As Satoshi, a nonviolence specialist who led trainings for DxE explained during one such event at a network-wide conference in 2017, “Teaching people not to be angry is very dangerous.” Martin Luther King, Jr. was “pissed off,” he said. What matters is where the anger is directed. When we take anger out on people, he said, they tend to react, and conflict escalates. Instead, anger should take the form of indignation toward unjust conditions. Satoshi gave the example of the beating of Civil Rights protesters by police on the Edmond Pettis Bridge in Selma, Alabama, on Bloody Sunday in 1965. The violence they endured without seeking retribution awakened the conscience of the public and resulted in growing support. In this way, the acceptance of suffering was both philosophical and pragmatic. One accepts violence against oneself because the creation of just conditions requires that the injustice of violence not be propagated further, by turning it against one’s adversaries. This moral demand also has strategic value, however, in that it inspires the sympathy of bystanders who may come to support one’s cause.

In these ways, nonviolence in DxE encompassed not only the absence of violence but also the disciplining, or guiding, of emotions in practice so that the ideals of the Beloved Community—the social manifestation of justice—may emerge. As such, nonviolence was not simply the means for achieving justice. Nonviolence was a technology that structured relations of thinking, emoting, and acting (one might say “being”) the manifestation of justice in the present. It was both the means and the ends. It was conceptually recursive, so that practicing justice is understood to make justice come to be. Interviews with DxE activists also showed how nonviolence was understood as a skill that required strengthening through repeated practice.

Historicizing nonviolence then adds complexity to these meanings. Explicitly and implicitly, DxE organizers’ references to previous nonviolent movements—and especially the Black Civil Rights Movement—were used to give moral and political legitimacy to the movement for animal rights. But where previous movement actors used nonviolence in part to establish their own humanity in the face of injustice, DxE’s more-than-human goals complicated the moral meanings of nonviolence. DxE activists, after all, were not fighting for their own humanization but rather for the moral standing of nonhuman others. Was it right to draw connections to the struggle for Black freedom? Further, the rise of European fascism and the dropping of the atomic bomb in Japan challenged Gandhi himself to reconsider whether nonviolence could be the universal solution to inhumanity he believed it to be (Devji, 2011).

For the learning sciences, this analysis provides an additional example of emotional configuration in the learning of social movement participants. Considering nonviolence as a kind of technology in transit clarifies the ways it structures the relations of meaning between feeling, conceptual sense-making, and practice. It also reiterates the importance of historical context for interpreting what emotional technologies for learning can do.

Emotion, data and place: Children's emotions emergent in ecologists' practices of sampling and data visualization

Kathryn Lanouette, William & Mary

Within the learning sciences and science education fields, there has been a growing focus on engaging young people in the construction and critique of data to support expansive learning opportunities (Wilkerson & Polman, 2020). Yet to date, such work has rarely focused on the emotional dimensions of these abstracting and authoring practices, particularly with children. In this paper, I focus on 10-11year old children's emotional experiences as they engage in sampling and data aggregation practices within an ecology unit centered around their schoolyard. I ask, what emotions emerge as children engaged in these practices and how does this intertwining of emotion, data and place shape their engagement in the practices and their reasoning about socio-ecological systems?

This work draws from a larger design-based research project that supported elementary students learning about complex socio-ecological systems and data using participatory GIS maps (Lanouette, 2019). Across ten weeks, 5th grade students studied the soil ecology literally underfoot in their schoolyard, exploring the question of "Who can thrive here?" by sampling invertebrates and soil samples in their schoolyard as well as recording above-ground human activities to understand the relationship among all these dimensions of the system. This design involved children in selecting sampling sites to study in detail, gathering data they were interested in and joining together to conjecture and contest relationships in collaboratively constructed visualizations of their aggregated data.

Through a longitudinal comparative case study analysis (Yin, 2017), I examine two student pairs' emergent emotions as they engaged in and adapted the ecologists' practices supported across the curriculum. Data sources include (a) video of class activity in one-on-one, small group, and whole group contexts and (b) paper and digital artifacts (children's note sheets, data visualizations). Analysis focuses on children's emotion within sampling practices (planning sites, selecting sites, collecting data at sites) and collectively assembled visualizations of their aggregated data (constructing bar charts and two-way tables). In coding emotion, I examined verbal expressions using emotion laden words (both in the moment and in reflecting on past events), multi-modal expression of emotion (Jaber & Hammer, 2016), and paralinguistic markers of emotion. By contrasting two pairs over time, I aim to illuminate not only the heterogeneity of emotions emergent within this design but also how children's emotions shaped how they selected schoolyard sampling sites, how they participated in collective constructions of their aggregated data and how they considered relationships within complex systems.

Several findings are noted here. Children's emergent emotions varied widely, ranging from delight and "love" of a schoolyard site to competition and exasperation, in turn shaping varying approaches to selecting sampling sites and representing data. For Amir and Marie, their joy in finding animals of any kind along with physically being in their favorite tucked away spot that Marie "just loves!" led the pair to repeat sampling at their site to see how the system might change over time (a key idea in ecologists' sampling practice) and to consider multiple interrelationships in the socio-ecological system. As they built a two-way data table with classmates showing all the invertebrate species discovered, their excitement for a mysterious animal they saw led them to insisting on showing it in the data, even though it was hard to categorize. In contrast, for Elena and Max, their focus on finding the most animals led them to constantly switch sampling sites that would ensure the highest counts. These feelings of competition emerged again as they were collectively building bar charts of earthworms counts, where the pair falsely elevated their data to ensure they had the highest earthworm counts among their peers.

Implications are twofold. First, these findings point to the import of attuning to the wide range of emotions emergent in constructing and contesting data, elevating not only children's warm emotions towards local places and more-than-human organisms within but also children's sharper emotions such as competition and exasperation. Given the larger norms, ideologies and power structures that shape emotional experience and expression (Vea, 2020b), this work suggests the import of making visible broader expressions in children's science pursuits as work in emotion, data and science practices continues. Second, these findings call for existing work in design-based research to more deliberately center children's emotions in the design of activities, the articulation of conjectures (Sandoval, 2014) and the study of learning processes.

Teacher learning in science labs: Affordances and constraints of emotional display rules

Shannon G. Davidson, Lama Z. Jaber, and Sherry A. Southerland, Florida State University

Science as a discipline has long been perceived as objective and, in turn, scientists have often been characterized as unfeeling or emotionless in relation to their work (Burbules & Linn, 1991). However, work of historians and sociologists of science and science education researchers provide ample evidence that affect is inherent in the doing of science (for examples, see Jaber & Hammer, 2016; Robbins, 1999) and that science is a social endeavor wherein emotional configurations (Vea, 2020b) are inherent. This affective dimension of science is not only part and parcel to professional science but central to the experiences of science learners. In order to support students' disciplinary engagement in science, teachers must understand and have facility with not only the conceptual and epistemic components of science, but also with the emotions that are part of disciplinary engagement (Davidson et al., 2020; Jaber et al., 2018). One context that aims to develop teachers' disciplinary understandings of and facility with science is that of Research Experiences for Teachers (RET) programs, in which K-12 teachers are immersed in extensive scientific research through work with scientists (Dixon & Wilke, 2007; SRI International, 2007). Although RET may provide teachers with firsthand emotional experiences in the doing of science (Davidson et al., 2020), teachers may not recognize these emotions as inherent to the discipline. Indeed, it is unclear whether RETs provide teachers a full grasp of science as a discipline, particularly with respect to recognizing the emotions that *scientists* experience in their work. To this end, our work considers the following question: What messages may be imparted to teachers about the role of emotion as an inherent dimension to the discipline of science through their encounters with scientists during an immersive research experience?

In this work, we argue that tacit yet influential emotional display rules (Diefendorff et al., 2006; Hochschild, 2012) may limit teachers' access to scientists' emotional experiences. Such rules shape how affect is or is not displayed in lab spaces, conveying meta-messages for teachers about what feelings and emotions are legitimate and acceptable in the doing of science. In turn, these tacit messages may actively shape the ways in which teachers come to develop their own attunement towards their emotional experiences in science and subsequently their students' emotions in the science classroom. To illustrate these dynamics and to explore the potential ways in which emotional display rules may moderate teachers' understanding of the affective dimension of science, we offer the example of Ava—a teacher participating in a six-week summer RET program at a national laboratory—and Dr. Ji, her mentor scientist. During one of the experimental cycles of Ava's research, there was a miscommunication of scheduling and a facility-wide routine power outage interfered with an overnight experimental trial that Ava and Dr. Ji were conducting. In reflecting on this moment in an interview, Ava noted:

> I felt really frustrated and upset when the furnace must have shut down during our trial run, --like what do we do? How can we fix this and run it again? But [Dr. Ji] was like 'No no no don't worry. This happens. This is part of it--part of, you know, science.' He didn't make me feel bad, but [rather] it's just part of science.

In this example, Dr. Ji makes moves to support Ava by normalizing the error as 'just part of science' and by telling her not to worry. In addition, as evidenced from field notes, Dr. Ji went on to tell Ava an anecdote of how this exact situation had happened to him once before when he was new to the lab. He described how he was 'confused' but once he'd realized the mistake he 'had to laugh and start over.' While Dr. Ji did make moves to support Ava by normalizing error and offering commiseration through the anecdote, he did not explicitly acknowledge Ava's frustration. Instead, his moves subdued those feelings. Additionally, Dr. Ji did not himself demonstrate any emotional reaction to this setback.

In light of these reactions from Dr. Ji, it is possible that Ava could walk away from this encounter with the understanding that scientists somehow lack emotion within their work or do not experience affect within the doing of science. Evidence for this internalization can be found in the observation that for most of the RET teachers, their own displays of emotions within lab spaces were very restrained and limited. Instead, these emotions (frustrations, vexations, excitements, and insecurities) were only expressed in other spaces (lunch times or social events) with fellow RET participants. This suggests that RET teachers may implicitly come to view their own emotions as somehow 'other' or unacceptable in science.

Emotional display rules related to science spaces have the potential to reinforce positivist views (Burbules & Linn, 1991) that science is an objective discipline which strips science—and those who do science—of their humanity. If teachers walk away from encounters with scientists that paint doers of science as emotionless, they may unintentionally reinforce this erroneous and stereotypical narrative in their classrooms, reproducing marginalizing ideas of who feels welcome in science and science spaces.

Abstract: This symposium explores multiple perspectives on integrating virtual experiments in science education. The papers report on virtual experiments as replacements for physical experiments or as supplements to physical experiments at several educational levels (i.e., preschool, middle school, and university) and for varied learning objectives. The six papers in the symposium analyze ways to design guidance and scaffolding for virtual laboratories; illustrate how virtual experiments could supplement physical experiments in a school science lesson; and assess how a combination of virtual and physical experiments affects learning. The symposium includes an interactive discussion of the implications of virtual experiments for the future of science education.

Acquiring knowledge and skills in the subject area of science is essential for full participation in today's knowledge society. The ability to understand and use scientific concepts and methods is a fundamental aim of science education (NRC, 2015). Implementing laboratory experiments in science education following inquiry-based learning scenarios can foster this understanding. To succeed, inquiry learning processes need adequate support (Lazonder & Harmsen, 2016). Recently, technological advances have entered classrooms. Digital technologies provide new possibilities and perspectives for virtual experimentation and interactive simulations. Typical experimentation in physical (hands-on) laboratories can be enhanced by virtual experiments that have both practical advantages and unique affordances for learning, e.g., faster manipulation of variables than in physical experiments, integration of multiple representations, the possibility to perform accurate measurements and the opportunity to make abstract or invisible objects and constructs observable for students. In order to effectively use virtual experiments for science learning, it is important to gather a deep understanding of learning with experiments, physical and virtual. This symposium provides a comprehensive overview of research on science learning with virtual experiments from multiple perspectives. Following the conference theme "Reflecting the Past and Embracing the Future", we consider learning with typical physical experiments as well as learning with virtual experiments. We report on high quality studies using qualitative and quantitative data. The six studies in this symposium deal with implementation, scaffolding, and combining physical and virtual experiments. They show how well-designed learning settings with virtual experiments can improve science education courses in the future.

First, Yvoni Pavlou, Marios Papaevripidou, and Zacharias Zacharia investigate the development of conceptual understanding in preschool children before, during, and after learning with either physical or virtual manipulatives using semi-structured interviews and combining quantitative and qualitative findings. They found no differences in conceptual understanding between students' learning with physical or virtual manipulatives. These results extend research with virtual manipulatives to preschoolers. Second, Sadhana Puntambekar and Dana Gnesdilow explore how virtual labs, in comparison to physical labs, support seventh and eighth grade students' ability to apply their knowledge to a real-world scenario and set up a subsequent, more complex physical lab.

They found that students working with virtual labs were better able to apply their knowledge and were also successful in setting up the subsequent physical lab. Third, Hasan Ozgur Kapici, Hakan Akcay, and Ece Ebrar Koca compare virtual and physical laboratories in the context of written argumentation of pre-service science teachers. They found that pre-service science teachers working with virtual or physical laboratories did not differ in their writing quality. Fourth, Yoana Omarchevska, Andreas Lachner, and Katharina Scheiter focus on supporting university students' inquiry learning using video modeling examples and monitoring prompts. They found that video modeling examples were beneficial for improving participants' hypothesis and argumentation quality and had no additional benefit from prompts. Fifth, Xiulin Kuang, Tessa H. S. Eysink, and Ton de Jong investigate how providing secondary school students with adaptive domain information can support their hypothesis generation and learning outcomes. Last, Salome Wörner, Jochen Kuhn, and Katharina Scheiter focus on how best to combine virtual and physical labs. In their study, seventh grade students worked with virtual and physical labs on the same topic in a different sequence, whereas the control group only worked with the physical lab. The discussant Marcia C. Linn will identify themes across the presentations and suggest next steps.

Comparing the impact of virtual and physical manipulatives on preschoolers' understanding in the domain of balancing a scale

Yvoni Pavlou, Marios Papaevripidou, Zacharias Zacharia

Introduction

Numerous studies have focused on investigating the impact of experimentation on learners' conceptual understanding (e.g., Zacharia et al., 2012) in various science domains and contexts with the use of Physical and/or Virtual Manipulatives (PM and VM respectively). In the context of balancing a scale, two critical variables are involved: the mass of the objects placed on the scale and their distance from fulcrum. Understanding the impact of the combination of the variables on the balance of a scale can lead to a rule/third defining variable, namely torque, which can be used for predicting the behavior of a scale. Children's performance with such type of activity provides insight into their complex thinking and how they combine variables (Pine & Messer, 2003). Despite the added value of experimentation, its integration in the learning process has not been investigated to the extent that researchers and educators could point to its optimum enactment, especially for early childhood education. Consequently, this study investigated whether the use of PM or VM during experimentation affects preschoolers' learning in the domain of balancing scale, by addressing the following research question: How does preschool children's development of understanding in the domain of balancing a scale compare before, during and after their exposition to PM and VM experimentation?

Method

The participants of this study were 88 preschoolers (age mean = 5,4) who were equally separated into two subgroups according to the type of experimentation (PM or VM) they used during a semi-structured interview. The interview followed the Predict-Observe-Explain (POE) strategy. The first part of the interview included an initial evaluation which was orally administered. The second part involved the experimentation with VM or PM and the third part was the oral re-administration of the same assessment items of the first part (final evaluation) for both groups. The PM experimentation involved the use of concrete instruments and objects (balance scale and weights). VM experimentation involved the same instruments and objects used in the PM condition, but in a simulation environment that retained the features and interactions of the subject domain of the study as PM did. The only difference between the two conditions was that only the PM condition offered actual, active touch sensory input, whereas in the VM condition only visual feedback was available. Data sources involved participants' responses to the clinical interviews. The data were treated both qualitatively and quantitatively. Open coding was followed for the qualitative treatment of participants' responses to identify their ideas. The quantitative treatment involved scoring through rubrics the pre- and post-test and participants' responses during experimentation. Non-parametric tests were used for the analyses.

Results and discussion

Participants' most frequent ideas during the three interview phases are summarized in Table 1 and are elaborated in the following. Comparisons within the conditions showed statistically significant ($p < .05$) variations (increase or decrease) of the use of an idea during the three phases. The most predominant idea during the initial evaluation concerned the mass of the objects (i.e. *"the scale tilts towards the side of the heaviest weights"*). In the experimentation phase there was a statistically significant decrease of the use of the mass-related idea, whereas the use of the distance-related idea (i.e. *"the scale tilts towards the side in which the weights were placed in a* *greater distance from the fulcrum"*) increased significantly before and after experimentation. These findings indicate an initial understanding of mass as a factor affecting the behavior of a scale and the development of understanding of the effect of distance as a result of experimentation. The more complex idea (torque) appeared during the experimentation and final evaluation in both conditions but not as frequently, indicating that children at this age tabletend to focus on one variable to predict and explain the behavior of the scale. The comparison between the conditions revealed that even though both VM and PM were conducive to student learning, no statistically significant differences were found learning-wise before, during and after the experimentation ($p > .05$).

Table 1: Percentage of appearance of most frequently used ideas during the three phases of the interview and the statistical significance of the comparison of the impact of PM and VM

Main ideas	Initial evaluation		Experimentation		Final evaluation	
	PM	VM	PM	VM	PM	VM
Mass	60%	47%	22%	42%	48%	39%
Distance	16%	17%	42%	39%	39%	39%
Torque	0%	0%	17%	13%	9,5%	7,6%

Overall, the findings of this study designate that preschoolers can develop understanding through experimentation for each variable affecting the balance of a scale independently, whereas the understanding of the interaction between the variables (torque) is a much more complex process. Also, there was no prevalence of PM or VM on students' conceptual understanding in this domain, a finding which indicates that VM could be used as means for experimentation under certain conditions even at preschool level as well.

The effect of physical and virtual labs in supporting middle school students' application of science ideas

Sadhana Puntambekar, Dana Gnesdilow

Introduction

Research comparing students' learning from physical versus virtual labs has shown that engaging students in virtual labs supports their science conceptual learning as well as or better than physical ones (D'Angelo et al., 2016). However, few studies have explored if there are any drawbacks from learning from virtual experiments when it comes to applying the ideas learned to new situations. Further, few physical versus virtual studies have assessed students' learning of practical skills, such as the ability to conduct subsequent physical labs (Brinson, 2015), so that students can not only learn science ideas "but can also apply them to explain phenomena or solve problems" (NRC, 2015, p.20). We explored whether doing a virtual versus a physical lab supported students' ability to apply what they learned to a real-world scenario and to set up a subsequent, more complex physical lab. Our questions were: 1) Are students who conduct virtual labs able to apply what they learned to explain the science behind a novel, real-world scenario as well as students who conduct physical labs? and 2) If students conduct a virtual lab, are they able to set up a subsequent, more complex physical lab as well as students who conducted the first lab physically?

Method

Five hundred and fifty-two seventh and eighth grade students from two different school districts in the midwestern United States participated in this study. We randomly assigned each of the participating seven teacher's in-tact classes to the Physical Lab (PL) or Virtual Lab (VL) condition. We used data from a total of 385 students (PL $n = 180$; VL $n = 205$) for this study. Students participated in a two week-long pulley unit. After taking a pretest, students were presented with a pulley challenge and engaged in cycles of inquiry to set up and test pulley systems with physical or virtual materials. They took a post-test at the end of the unit. We assessed students' learning of science concepts, as well as their ability to apply their knowledge to a new context or set-up a physical lab. First, we used a 15-question pulley content test to assess students' understanding of pulleys. We analyzed the test scores using an Analysis of Covariance (ANCOVA). Second, we assessed students' ability to apply what they learned during a physical or virtual lab to a new context using the *real-world scenario application questions*, which asked students to examine three pictures of a well with different pulley systems and explain which pulley system gave the most mechanical advantage. Students' reasoning was coded based on a rubric of how pulley systems can affect mechanical advantage. Students earned one point for including any accurate reason (Cohen's Kappa of .945 on

20% of data). We then used Chi-Squared tests of homogeneity of proportions to understand if the number of students who provided the correct answer on the real-world scenario as well as the types of reasons provided were different by condition. Further, to see whether students in the VL or PL condition provided more or less reasoning in their answer, we calculated a total explanation score by condition and conducted an Analysis of Variance (ANOVA). Finally, we tracked how long it took 133 student groups (PL groups = 66; VL groups = 67) to set up a complex pulley system in our *physical application task* and averaged time data by condition and analyzed it using an ANOVA.

Results and discussion

We found that students in the VL condition learned more about the physics ideas related to pulleys than students in the PL condition with a small effect size ($F(1,384) = 4.307$, $p = .039$, $\eta^2 = 0.011$). We also found that a significantly higher proportion of students in the VL condition answered the real-world scenario application question correctly (VL 91% vs. PL 80%, $z = 8.16$, $p = 0.004$). Further, a significantly higher proportion of students in the VL condition provided reasoning about the following: i) the pulley had more mechanical advantage because you would need to pull a greater distance, i.e., the force–distance trade off; (VL 7.3% vs. PL 2.2%, $z = 5.45$, $p = 0.02$); ii) stated the correct amount of MA, (VL 5.4% vs. PL .6%, $z = 5.84$, $p = 0.0016$) and iii) included more reasons to back up their ideas than students in the PL condition (VL mean explanation score(SD) = 0.93(0.2); PL explanation score(SD) = 0.64(0.77); $F(1,383) = 12.50$, $p < 0.000$). Finally, the average time it took for student groups in the PL versus VL condition to set up a more complex pulley in our physical application task showed that there were no significant differences between the two groups (PL mean time(SD) = 20.64(8.49) minutes; VL mean time(SD) = 20.13(8.62) minutes; $F(1,131) = .732$, $p = 0.732$).

Our findings further establish virtual experiments as effective instructional tools to support learning. In line with prior research we found that students who performed a virtual versus physical lab learned significantly more science content. However, we also found that conducting virtual labs may also better support students' ability to apply their ideas to a new real-world scenario as well as to provide scientifically accurate reasons in their explanations, without negatively affecting their ability to set up and conduct a subsequent physical experiment. While physical experiments are essential for helping students to truly learn science (Lehrer & Schauble, 2015), our findings may give practitioners greater confidence in using virtual simulations as meaningful and effective tools to support students' learning and application of scientific knowledge.

Assessing the written arguments developed in hands-on and virtual laboratories

Hasan Ozgur Kapici, Hakan Akcay, Ece Ebrar Koca

Introduction

The goal of the current study is to examine the characteristics of arguments (e.g., quality of claims, questions, evidence, and multiple representations) created by pre-service science teachers (PSTs) by using the science writing heuristic (SWH) approach in a virtual laboratory and comparing it to the hands-on laboratory. Based on the goal, the main research questions for the study were the following: (i) what are the features of PSTs' written arguments based on the experiments in a virtual laboratory?, (ii) what are the features of PSTs' written arguments based on the experiments in a conventional hands-on laboratory?, and (iii) What are the similarities and differences between PSTs' written arguments based on the experiments in a conventional hands-on laboratory and a virtual laboratory?

Method

A quasi-experimental research design was used in this study. Two groups were included in the current study: One of them designed and implemented their experiments in the conventional hands-on laboratory and wrote their arguments on the paper-based laboratory worksheet; the other group did their investigations through the virtual laboratory and used the online learning platform to write their arguments. The study was done with 52 PSTs (40 female, 12 male; $M = 21$ years, $SD = 1.30$) from a public university in Turkey. There were 28 PSTs in the control group, where conventional hands-on laboratories were used to design and implement experiments and laboratory worksheets were used to write their arguments. In the experimental group, there were 24 PSTs, who used the virtual laboratories to design and implement their experiments, and the online platform was used to write their arguments. The writing template, developed based on the SWH approach by Choi (2008), was used in the study. The template involves five main elements as following: preparation for experimentation, predictions, investigation, results, and discussion. First of all, two theoretical approaches (argumentation and writing to learn) were discussed with the PSTs. After this, PSTs worked in the laboratory environments for his/her group's assigned condition. Each PST designed and implemented his/her own experiments and wrote arguments alone for four different experiments, related to solutions, acid and base, electricity, and buoyancy force, respectively. PSTs' writing samples were collected over a period of four weeks. Both of the groups had the same amount of time for each experiment (90 min per experiment). The main difference between the two groups was the laboratory environment. The same instructor taught both of the groups. An open inquiry-based learning approach was used in this study. The main topic was provided to the PSTs and then they followed the sections of SWH approach individually. At the end of the study, PSTs writings for four experiments were collected and analyzed based on the SWH approach. The PSTs' science writings were transformed from qualitative data to quantitative data by using the rubric developed by Choi (2008).

Results and Discussion

The results showed that the features of written arguments created by PSTs from both of the laboratory environments were at an intermediate level. The written arguments for both in the hands-on and virtual laboratory environments showed that whereas the highest average score was found for the section about claims-evidence relationship (3.85/5.00 for the ones in the hands-on lab; 3.89/5.00 for the ones in the virtual lab), the lowest score was found for the multimode section (1.86/5.00 for the ones in the hands-on lab; 2.34/5.00 for the ones in the virtual lab). Furthermore, PSTs who used the virtual laboratory posed better testable questions ($F(1, 207) = 2.391$; $p = .018$; $d = 0.34$), presented strong and valid evidence ($F(1, 207) = 2.093$; $p = .038$; $d = 0.30$), and used multiple representations better ($F(1, 207) = 3.318$; $p = .001$; $d = 0.47$) than their counterparts in the hands-on laboratory. For posing better testable questions, computer technology or the Internet can be reasons for this result because the PSTs in the virtual laboratory had the opportunity to design more complicated experiments. For presenting strong and valid evidence, being able to use online scaffolding tools, which enabled PSTs to correlate their findings with their questions or claims, can be a source for this outcome. For the multimode representations, indeed, PSTs in both of the groups used multiple representations occasionally. Even so, whereas PSTs in virtual laboratory environments were able to show data in graphs or tables, PSTs in the hands-on laboratory environments mostly focused on writing rather than drawing tables or graphs. All these findings show that an important conclusion of the current study is that the SWH approach can be used well in virtual laboratory environments as much as in hands-on laboratory environments.

Supporting learning with virtual experiments using video modeling examples and monitoring prompts

Yoana Omarchevska, Andreas Lachner, and Katharina Scheiter

Introduction

Scientific reasoning and argumentation are crucial facets of scientific literacy and their development has become a fundamental aim of science education. Students often have deficits in scientific reasoning, in particular with developing hypotheses and designing experiments to test them. One explanation for these deficits is that scientific reasoning and self-regulation are rarely integrated. Guided inquiry learning (using instruction or scaffolds) can be more effective than traditional teaching methods for enhancing scientific reasoning. Video modeling examples (VME) are effective for teaching scientific reasoning (Kant et al., 2017). We combined VME with prompts to activate the prior strategies taught in the VME and to foster monitoring of scientific reasoning activities during inquiry. Against this background, we tested the effectiveness of combining support measures which integrate self-regulation and scientific reasoning. We compared participants' hypothesis and argumentation quality in two tasks between conditions. We hypothesized that 1) students who received VME and monitoring prompts (VMEP) would have higher hypothesis and argumentation quality than students who received VME only, and that 2) VMEP and VME would outperform students who received no VME and prompts (control).

Method

Participants were 127 students from a University in Southern Germany (26 males, $M = 24.3$ years, $SD = 4.81$) from various study programs. In the videos, a female model explained how to formulate a good hypothesis and what is important before collecting data. Then, she conducted several experiments and evaluated the results. We used a coping model, which initially made a mistake, but then corrected herself to model metacognitive monitoring. We used three virtual experiments from Gizmos: *Archimedes' principle, Photosynthesis*, and *Energy Conversion*. In each task, participants were given a research question. They wrote down a hypothesis, collected data using the virtual experiments, and wrote down an answer on an experimentation sheet. We created three monitoring prompts (P), which guided students to specific scientific reasoning activities. In the VMEP condition, participants watched the VME and received the prompts (P) during the training task. Then, they solved the transfer task. The VME condition had identical procedure, excluding the monitoring prompts. In the control condition (unguided inquiry), instead of watching the VME, participants solved the same task as the model using the same virtual experiment. Hypothesis quality was measured by its testability and correctness (0-4). Argumentation quality was scored based on quality of the claim, evidence, and reasoning (0-6). Two independent raters coded the entire dataset containing two hypotheses and two answers for each participant. They discussed all disagreements until 100% consensus was reached. Screen captures and think aloud protocols were used during participants' inquiry learning to obtain process data on self-regulation and scientific reasoning. We combined findings from two process analyses (epistemic network analysis and process mining) to investigate the processes of self-regulation and scientific reasoning in different conditions.

Results and discussion

Compared to the control group, VMEP and VME had higher hypothesis quality, $F(2, 124) = 3.79$, $p = .025$, $\eta^2 = .05$, and argumentation quality $F(2, 124) = 3.43$, $p = .035$, $\eta^2 = .06$ in the training task. In the transfer task, VMEP and VME had higher hypothesis quality, $F(2, 124) = 4.71$, $p = .011$, $\eta^2 = .07$ than the control condition, but the three groups did not differ in argumentation quality, $F(2, 124) = .60$, $p > .05$, $\eta^2 = .01$. The two VME conditions did not differ, indicating no added benefit of the monitoring prompts. Similarly, on the process level, we found significant differences between the two VME conditions and the control condition, but no differences between the two experimental conditions. Detailed process results will be presented at the conference.

The aim of this study was to test the effectiveness of VME and monitoring prompts for enhancing hypothesis and argumentation quality. Our results indicate that VME improved hypothesis quality in the training and transfer tasks. Watching VME improved argumentation quality in the training task, but this improvement could not be replicated in the transfer task. We found no added benefit of the monitoring prompts. On the process level, we observed a similar pattern of results - we found differences between the two VME conditions and the control condition, but no differences between the VME conditions. Our findings highlight the potential of VME for supporting scientific reasoning during inquiry learning. Thus, teachers and educational practitioners can benefit from using VME in combination with virtual experiments to teach scientific reasoning.

Effects of providing adaptive domain information on facilitating hypothesis generation in simulation-based inquiry learning

Xiulin Kuang, Tessa H. S. Eysink, Ton de Jong

Introduction

Hypothesis generation is widely regarded as a central process of inquiry learning (de Jong & van Joolingen, 1998; Zimmerman, 2007). It triggers students to mindfully consider a problem to be addressed and to consciously organize their tentative explanation or solution to the problem into testable statements. The logic expressed in testable hypotheses can guide conscious processing in subsequent inquiry processes, such as experiment design, data collection, and data interpretation. One principle of inquiry learning is for students to actively develop knowledge about a domain that they are relatively unfamiliar with (Lazonder et al., 2009). But how can we realistically expect students to generate hypotheses if they are novices of a domain? Noticing what important variables to be considered, and what possible relationship can happen between variables requires basic domain knowledge, which students may lack. Empirical studies have confirmed that providing domain information to students with low prior knowledge can facilitate students' knowledge acquisition on the domain and encourage more hypothesis-driven behavior (Lazonder et al., 2010). Yet in practice, students in the same class may have different levels of prior knowledge. The expertise reversal effect, promoted by Kalyuga et al. (2003), argues that instructional formats that are effective for learners with low prior knowledge could be ineffective, or even deleterious for learners with high prior knowledge. Providing fixed, identical domain information to all the students may not end up with the same positive outcome. Information technology makes it possible to automatically provide information adaptive to different inputs. The effect of providing adaptive domain information based on students' level of prior knowledge on facilitating their hypothesis generation process is a question not addressed by earlier studies. Hence, the present study aims to detect whether providing adaptive domain information is an effective way to foster students' hypothesis generation and knowledge acquisition in simulation-based inquiry learning.

Method

Participants were 153 secondary school students (11-13 years old) from Italy (n = 70) and Romania (n = 83). Students from each class of the target schools were randomly assigned to two conditions, either with or without the adaptive domain information. Students worked with a sequence of learning phases in a simulation-based inquiry learning environment on a physics topic force and motion. These learning phases covered all the major inquiry processes, including presenting an inquiry question, hypothesis generation, experiment design, data collection, and drawing conclusions. The adaptive domain information was provided after presenting the inquiry question and before students write their hypotheses. The domain information was made adaptive by two steps. First, a list of both relevant and irrelevant variables on force and motion was shown in a Selection tool. Students were asked to select variables that they thought were important to be taken into consideration to answer a given question. To identify decent selection, students were also asked to indicate general relations between variables by dragging lines between variables. Second, based on students' variable selections and indicated relations, domain information that varies in levels of detail about each variable was automatically shown. The domain information is adaptive in the sense that different students may be presented with an introduction of a variable in three different levels of detail: a full introduction, a less extensive introduction, or no instruction. As for a full introduction, the definition of a variable will be firstly introduced by referring to a common phenomenon of daily life and/or showing a picture, and then some practical information or examples about how to measure or how to record the variable will be included. The less extensive introduction will only include the latter part of the full introduction. No instruction means no further information will be shown to students. Three aspects were taken into account to decide which level of domain information to be presented: whether a variable is relevant or not, whether a variable is selected or not, and whether possible general relations were correctly indicated or not. Students' knowledge acquisition will be assessed by comparing their score of knowledge tests before and after the inquiry learning task. A coding scheme will be designed to code the testability and complexity of students' hypotheses.

Results and Discussion

Data collection is currently taking place. The results and the discussion based on the results will be presented at the conference.

Combining physical and virtual experiments in physics education

Salome Wörner, Jochen Kuhn, Katharina Scheiter

Introduction

The ability to understand and use scientific concepts and methods has become a fundamental aim of science education. To improve the understanding of both science content and scientific practices, the use of experiments for inquiry-based learning can provide valuable learning opportunities for students. Digital technologies can enhance learning from traditional physical (hands-on) experiments (PE). Virtual experiments (VE), for example, provide further observation and modelling opportunities while still allowing interactive and self-directed experimentation and manipulation of variables. On the other hand, VE lack the hands-on experience and the authenticity of the PE. Thus, VE and PE have complementary affordances, which may have unique benefits for learning. In line with this reasoning, de Jong et al. (2013) and Kapici et al. (2019) showed that students who learn with combinations of PE and VE in most cases outperform students who learn with PE only or VE only. They conclude that well-designed combinations of PE and VE allow students to gain a more nuanced understanding of scientific phenomena. However, there is little evidence so far on how those 'well-designed combinations' should ideally look like to maximize the learning outcome during inquiry learning. Therefore, this study provides a first step towards addressing this question by investigating whether the sequence of the experiments (VE first or PE first) influences the students' conceptual understanding of the lessons' topic. Additionally, the combination of the experiments was compared with a control group of students who conducted the same experiments, but as PE only.

Method

In this study N = 124 students from five seventh grade classes from the highest track of the German school system participated. However, due to missing data for some students this number decreases to n = 80 complete data sets (pre-test, worksheets, and post-test). The topic of the lesson was converging lenses (physics, geometrical optics) and the refraction of light rays through a converging lens which forms an image of the object. In the VE we used for this study the following variables can be manipulated using sliders: thickness of the converging lens, height of the object, and distance between object and lens. These variables can also be varied in the PE. However, the VE is more abstract showing a schematic view of the lens, the object, and the image of the object. Additionally, the path of light refracting through the lens and the three construction lines can be observed in the VE. The students worked with the VE on iPads. All participants were randomly assigned to one of three conditions within classes (between-subjects design): (1) PE only (control condition) or (2) sequence VE – PE or (3) sequence PE – VE. Before the experimentation phase all participants received an introductory lesson on the converging lens and its functions. During the following experimentation phase participants worked together in groups of two to three students, guided by a worksheet detailing the tasks that students had to perform. These tasks required the students to investigate how the thickness of the lens, the height of the object, and the distance between object and lens affect the image resulting from using the converging lens. Each participant completed a test of conceptual understanding three times: one week before the intervention (the physics lesson) as a pre-test to measure the prior knowledge of the students, one day after the intervention (immediate post-test) and approx. eight weeks after the intervention (follow-up-test). Items are constructed in a way that they address well-known misconceptions of students. Process data was collected through video and audio recordings of students during the experimentation phase as well as recordings of the iPads' screens during the VE and analysis of the students' worksheets.

Results and discussion
Results and discussion of this study will be presented at the ISLS Annual Meeting 2021.

Abstract: This symposium addresses dance as a site for STEM learning. We present papers from five research projects that each sought to engage youth in embodied STEM learning using dance, exploring the power of creative embodied experiences and the body's potential as an expressive tool and resource for learning. We show how dance activities expanded access to STEM and supported sense-making; how dancer and dance-making practices were leveraged to support computational thinking, modeling, and inquiry; and how moving bodies in creative ways helped to generate new insights by allowing for new perspectives. Across our work, we seek to understand the multiple, rich learning opportunities that emerge from working across the arts and sciences, dance and STEM. Together our research shows that attending to opportunities for STEM engagement and learning through dance practices can broaden access to learning and engagement in STEM for all.

Session overview

"We want to dig down deeply in understanding movement as a site of knowledge, so that dance is placed at the center rather than the periphery of interdisciplinary dialogue"
- Norah Zuniga Shaw, Synchronous Objects Project

The notion that thinking is an "embodied" activity, that the active human body as a whole, not just the brain, is involved in how we conceptualize situations, has been developing for decades in the writing of philosophers, cognitive and learning scientists (Merleau-Ponty, 2002; Lakoff, 2012; Varela, Thompson, & Rosch, 1991; Goodwin, 2000; Streeck, Goodwin, & LeBaron, 2014). However, embodied cognition literature has yet to explicitly address movement as a creative, cultural, and expressive medium. A notable absence of thought remains around ideas of the body and bodies as conversational and expressive, and a particular gap exists when it comes to STEM learning through creative-expressive-embodied dance activities. Each paper in this symposium contributes to a collective re-conception of STEM embodiment by focusing on how youth use expressive movement to engage with ideas as they explore STEM in formal and informal learning environments.

Embodied cognition in the learning sciences has focused on important work in which body movements augment technological environments to support deep disciplinary learning. Rooted in gesture studies, this work situates intuitive embodied experiences as a developmental beginning towards internalizing concepts cognitively (Abrahamson & Lindgren, 2014). We offer an alternative framing of embodiment where the expressiveness of full-bodied coordinated movements themselves are the means and ends of learning (Marin et al., 2020). This new framing of embodiment allows us to see dance as a medium for engaging in STEM-based inquiry. Dance invites us to move in solidarity with one another, exploring our world through our whole bodies and our whole selves, the cognitive, creative, emotional and the logical. It affords multiple ways of bodily knowing, access to multiple perspectives, as well as physical, emotional and affective stimuli, and dance practices can be valuable resources for inquiry and problem solving. The challenge of *Reflecting the Past and Embracing the Future* extends to us the opportunity to understand STEM learning as it is and imagine it as it could be, as creative and embodied.

Through this symposium, we invite participants to explore the power of creative embodied experiences and of the body's potential as an expressive tool and resource for learning. We hope to engage in a broader conversation about embodiment by sharing data that shows how dance activities can expand access to STEM and support STEM sense-making; how dancer and dance-making practices can be leveraged to support computational thinking, modeling, and inquiry; and how moving bodies in creative ways can help to generate new insights by allowing for new perspectives. We have organized the presenters temporally, working from 2017 up through 2020 when the global COVID pandemic upended our ability to move in co-present spaces, as we acknowledge how the virtual re-mediation of our lives has impacted our understandings of the body now and for the future. The symposium will be organized as follows: (1) co-chairs will lead an embodied warm up to contextualize issues across projects (5 min); (2) each project will present (12 min); (3) the co-discussants will pose questions and implications across the collective work (10 min); (4) we will take questions from the audience (15 min).

Dance/Making: Integrating STEM and arts across 3 dimensions

Dionne Champion, University of Florida

Dichotomous ways of thinking that privilege science over art, thinking over doing, the immaterial over body and logic over emotion or creativity have led to narrow perceptions of science as disembodied, emotionless, objective, and lacking creativity (Bowman, 2004; Brickhouse, 2001) and to equally narrow perceptions of art as frivolous, irrational and non-cognitive. Despite research that has begun to recognize the value of learning at the intersection of science and arts and of embodied science learning (Johnson-Glenberg et al., 2014; Abrahamson & Lindgren, 2014; Root-Bernstein et al., 2011), there have been few studies focused on understanding dance as a creative-expressive-embodied resource for STEM problem-solving and sense-making.

This paper explores dance as a resource for STEM learning in the dance makerspace, a 4-week summer program that challenged youth (ages 9-14) to engage in dance/Making, a process of making with movement, materials and bodies. Youth in the dance makerspace choreographed projects that explained science phenomena using movement and music, physical and computational tools, kid-friendly electronic elements (i.e. LED lights, Arduino boards, conductive clay), and other materials. The design-based research intervention was developed to explore the affordances of dance as an interest, a creative practice, and a way of knowing and to explore the relationships between "making to learn" and movement and dance for African American youth who often experience marginalization around science and technology and end up positioned as disinterested in science.

Utilizing a lens of representational mediators and practices (Danish et al., 2007), video data from the 4th and final iteration of the study was analyzed to understand how youth drew on STEM practices to inform their creative dance/Making process and how the process of dance/Making expanded their engagement with science and technology. Findings show that the process of dance/Making supported interdisciplinary problem solving, sense-making and sustained science inquiry. The following example featuring one project group, *Stardust* (a group of five girls who developed a choreographic representation of Saturn), demonstrates three ways that youth blended artistic and scientific practices to support science sense-making: integrating dance and technology to develop their choreographic explanations, developing an integrated art/science practice of modeling (Enyedy et al., 2014; Root-Bernstein et al., 2011), and combining narrative and analytical ways of thinking in their choreographic explanations (Bruner, 1987).

Dance and Technology. To develop a choreographic explanation of the formation of Saturn, its rings, and Roche limit (the invisible barrier around the planet; the minimum distance at which an object can approach without being disintegrated), Stardust created a representation that used dance and technology to highlight many essential ideas. They designed and constructed a foam model of Saturn mounted on a rotating electric motor with LED light dust and ice particles. They used dancers to play the role of gases and heavier elements drawing together under the force of gravity to form the planet and its Roche Limit. They utilized technology to enhance the ideas they articulated with their bodies (representing the particulate nature of the rings with LED lights while representing orbit with movement); interacted with it as a prop to help explain the phenomenon (spinning model of Saturn as the planet); and integrated it into their movement phrases ("becoming" Saturn as a way to switch the motor on). Embedded in their attempt to bring their choreographic ideas to life were design conversations that required them to attend to and understand the technologies they wanted to employ (e.g., how to wire and power the LED lights and fan motor needed to represent ice and dust particles of Saturn's rings). Their representational choices reflected their understanding of the phenomenon and offered opportunities to develop technical skills related to engineering, circuitry, and design through the dance/Making process.

Blending Art and Science Practices. To create their project, Stardust engaged in the practice of modeling; however, this practice could not be defined as simply science, engineering, or art because it integrated science, engineering and art. It was a STEAM making practice that involved exploring science ideas using both STEM and arts as tools for making and investigation. Modeling as a dance/Making practice served a variety of purposes. The girls made models to provide inspiration for choreography, to brainstorm new ideas, develop prototypes, solve problems, figure out technical design features, work through their developing understanding of the scientific explanation of the phenomenon, and to represent aspects of planet formation in their final representation. They tried many different choreographic ideas as they thought through the best way to model the formation of Saturn's rings, embodying the objects that approach the planet and disintegrate into particles that would form rings. Modeling the phenomenon and iterating on their ideas impacted how they thought about the phenomenon, offering opportunities to experience aspects of it from multiple perspectives, and about the representational possibilities by prompting discussions about which features of the phenomenon were essential and which could be left out of their final representation.

Narrative and Analytical Ways of Thinking. As the girls began developing project ideas, they researched the process of planet formation as a way to inform their choreography. Their research raised new questions and new directions for exploration and provided opportunities to become familiar with the symbols scientists used to describe the phenomenon, which led to new knowledge that they used to make representational decisions. Science supported storytelling through dance, and the act of developing a narrative was a tool for understanding the science. In dance, narrative is a tool that can be used to structure the development of choreographic compositions (Wright, 2003). It allowed for flexibility in storytelling and the simultaneous exploration of multiple ideas. The girls used their choreography to simultaneously explain processes, causes and effects, and relations among aspects of the phenomenon, all placed within the context of a story about the formation of the planet. Dance in this context became a representational medium for both narrative and analytical (or paradigmatic) thinking, providing rich opportunities for integration of these explanatory approaches.

Dance/Making using materials, tools, and bodies to express and support their developing understanding of phenomena created opportunities for youth to shift how they engaged with and understood the science they studied. Youth explored science content and experienced STEM practices in the context of dance/Making, and as a result, were pulled into science phenomena in ways that became personally and physically engaging. This work has the potential to broaden and expand how we think about STEM learning by identifying ways in which embodied creative processes like dance/Making can be resources for science learning and ways that STEM can be a resource for creative thinking. This is critical for understanding learning in informal creative spaces, learning driven by movement, and learning for populations for whom movement and the body are valued cultural resources.

Exploring opportunities for embodied learning in dance/STEM with black girls

Folashade Solomon, TERC

The notion that thinking is an "embodied" activity – that the active human body as a whole, not just the brain, is involved in how we conceptualize situations – has been developed in the writing of philosophers such as Maurice Merleau-Ponty (2002) and of cognitive scientists such as George Lakoff (2012). Other researchers developing the field of embodied cognition have used evidence from linguistics, psychology and cognitive science-among other fields-to argue that all human cognition is embodied action (Lakoff & Johnson, 1980, 1999; Varela, Thompson, & Rosch, 1991). These researchers argue that both our most simple conceptualizations and our most complex problem solving are influenced by our bodies and are enacted in constant interaction with our physical environments. Building on this work, anthropologist Tim Ingold argues that whole body movement has not been deeply explored in the literature on embodied cognition and suggests that dance is an important type of embodied cognition (Ingold, 2011). Our paper explores the ways in which dance is a type of embodied cognition as well as an art form and affords access to cultural practice. The importance of dance in Black culture positions the artform as a site of rich identity and confidence for Black girls. In this paper, we examine the role of dance as an embodied resource for physics learning and explore how this culturally and personally expressive medium can expand access to physics for Black girls. We look closely at youth interactions in the Embodied Physics Learning Lab (EPLL), a program that invited 15 Black high school girls from two community-based dance centers to engage in embodied activities that combined dance and dance-making practices with physics to better understand how interdisciplinary approaches present opportunities to enhance engagement, provide additional lenses for meaning-making, and foster meaningful connections to physics.

We engaged in an iterative process of design, observation and analysis of the Embodied Physics Learning Lab, utilizing design-based research (DBR) (Cobb et al., 2003) and responsive design approaches to design the lab and qualitative interpretive methods to understand participant perspectives and experiences (Denzin & Lincoln, 2008). Building on sociocultural perspectives, we designed an environment that recognized, respected and recruited youths' prior knowledge, cultural identities and practices to engage them in the study of physics. There are few studies that look at STEM learning environments, embodiment, and identity with underserved students. It is here that we situate our work - at the intersection of dance and informal science learning and identity studies primarily involving Black girls.

This paper focuses on project findings that show different uses of embodied learning in Dance/STEM to explore scientific phenomena. We share three types of embodied learning activities that enabled physics engagement and inquiry among teens in the learning lab as they used their bodies to think, investigate and model physics concepts and ideas: embodied imagining, kinesthetic experience and re-presentation. Embodied imagining involves exploring physics content through dance-making structures and practices; for example, engaging in sense-making through improvisation and imagery, (i.e. mobilizing dance to animate concepts in particle and quantum physics). Kinesthetic experience involves sense-making through one's own bodily experiences (i.e. exploring gravity's effect on your one's body by jumping while being lifted). Re-presentation, as defined by Champion (2018), involves interpreting, combining, reformulating, and translating ideas that were researched and collected about a phenomenon to create a new representation to re-present it in a new embodied form. Through a close analysis of the resources youth drew from in their interactions in the Embodied Physics Learning Lab, we show that movement, bodies, emotions and culture can be rich resources that, while sometimes seen as deficits, can be useful in supporting understanding and engagement with physics ideas. We argue that when repositioned as strengths, dance practices can act as powerful funds of knowledge for accessing these resources, giving Black girls new paths forward into physics.

Traditionally, physics is too often presented as a set of abstract and disembodied concepts. Engaging youth in learning approaches that leverage embodied sense-making allows them to use a fuller set of meaning-making resources to understand ideas, formulate descriptions, and express their understandings. Non-traditional forms of participation can encourage all students, especially those who might not otherwise participate, to enter academic conversations (Ballenger, 1997; Varelas, et.al., 2010; Warren & Rosebery, 1996). This work offers approaches for fostering more effective participation of underrepresented populations in art-based learning and STEM fields.

Dance as scientific inquiry: How does improvisational movement support collaborative sensemaking for young children?

Lindsay Lindberg, UCLA & Noel Enyedy, Vanderbilt University

Despite the growing momentum behind the STEM to STEAM (STEM + Arts) movement in K-12 education (Maeda, 2013), dance and other body-based artforms are rarely considered part of canonical science learning. However, research shows that dance adds a distinct layer of sense-making tools with which students and scientists can make sense of multidimensional scientific phenomena with their bodies (Ochs et al., 1996; Nasir, Rosebery, Warren, & Lee, 2006; Myers, 2012). Previous work has addressed using dance as a tool to represent already-learned knowledge (Zohar & Abrahamson, 2015; Myers, 2012), but those studies run the risk of discounting the role that active dance-making can play in supporting science sense-making. Rather than positioning dance as solely "an instrument for science communication" (Myers, 2012 p. 159), this analysis positions young science learners using their bodies and dance as "experimental media to generate insight into molecular forms" (Myers, 2012 p. 172). This analysis builds on the Learning in Embodied Activity Framework (LEAF) (Danish et al., 2020), and positions dance as a discipline and culturally specific practice that is distinct from, and intentionally supports collaborative science learning.

This analysis is part of a larger, multi-year design based research study (Design Based Research collective, 2003), iSTEP (Interactive Science Through Technology Enhanced Play). The project focuses on the ways in which young children (ages 6-7) engage with science learning in an embodied mixed reality setting through inquiry and embodied play (Danish et al., 2020; Enyedy et al., 2015). A seven-day unit explored particle behavior of both micro- and macro-states of matter using OpenPTrack technology which tracked students' speed and location, and communicated that to a projected simulation. Throughout the intervention, students learned that particulate matter in a solid moves slowly (vibrates in place), liquid particles move at a medium speed, and gas particles move quickly. This analysis looks closely at video data from the seventh and final day of data collection, wherein groups of four students choreographed and performed dances representing a state change (i.e., from liquid to gas). Using inductive methods and interaction analysis (Jordan & Henderson, 1995), we track the choreographic process and embodied activities of one group of 4 students and 1 researcher representing a state change from liquid (water) to solid (ice).

Our analysis demonstrates the multiple ways students make sense of and represent a scientific concept-water particle behavior as a liquid. Throughout the choreographic process, students' verbal descriptions of particulate behavior remained stable, while their movements demonstrated nuanced explorations of water particles in a liquid form. They generated and iterated movement ideas nine times over two minutes, representing particles while moving at both a medium speed and at a medium distance away from each other. Students used levels in two ways (standing high on tiptoes, squatting low towards the floor) to explore ways that particles could be standing in the same place "medium" distance apart. This analysis shows students using dance as one way to deepen their engagement with the science material, not to merely represent their already sealed canonical content knowledge about states of matter. Indeed, the process of choreographing scientific ideas, even when students have previously embodied the phenomena as a group, involves opportunities for new noticings that support learning. Dance is not simply a tool to present previously learned knowledge, but an opportunity to deepen understanding of canonical science content.

Students used multiple bodily movements and positions to represent the same verbal descriptions - "medium" speed and distance from each other. This matters because by limiting what we recognize as canonical science, we miss out on nuance that students pick up, embody, and express while engaged in dance as a sense-making process. This analysis shows students applying their embodied science knowledge to their choreographic processes, furthering past research that positions dance performance as a tool for students to develop their sense-making and argumentation around science (Lindberg et al., 2019). Dance added affective and embodied depth to the students' conceptualization of the canonical science knowledge, which is worthy of future investigation.

Developing computational double awareness through rule-based dance games

Lauren Vogelstein a ndCorey Brady, Vanderbilt University and Rebecca Steinberg and Curtis Thomas, Independent Dance Artists

Professional dancers' execution of choreography entails that dancers understand both how it feels to execute movement from within an ensemble of moving bodies and what the entire ensemble looks like to an outside viewer. This phenomena, referred to by dancers as "double awareness," gives dancers an intrinsic perspective from within while maintaining an extrinsic perspective without being an outside viewer. In this paper we explore how the practices of professional dancers can be leveraged for middle schoolers to develop a double awareness of computational agents by engaging together in rule-based dance games. This speaks to the importance of taking multiple perspectives in learning about the computational components of complex systems (Olson, 2015; Papert, 1980; Wilensky & Reisman, 2006; Wilensky & Resnick, 1999) and expands it through design based research (Design Based Research collective, 2003) that leverages the expressive practices of professional dancers engaging their whole bodies in movement together (Vogelstein, 2020).

This work reports on the design process and implementation of a one-week art and coding camp for middle schoolers. The camp was co-designed by the authors (one learning scientist and two professional dancers) and four math teachers with a goal of leveraging mathematical and computational connections between choreography and programming in an agent based modeling environment (NetLogo). Video recordings of designing and implementing the camp were analyzed using Interaction Analysis (Jordan & Henderson, 1995; Hall & Stevens, 2015) to explore the micro and multimodal nature of sense-making in interaction.

As an art and coding camp, our goal was for students to explore the expressive potential of computational environments physically and digitally. The soup game, a rule-based dance game suggested by Steinberg & Thomas, provided campers the opportunity to develop choreography quickly as an ensemble while co-developing an understanding of computational concepts (e.g. code specificity, agent interpretation, procedures, and conditional statements). Setting up the game involved campers creating a set of rules to follow (e.g. Rainbow Muffins meant everyone walked forward a random number of steps less than 21 in whatever direction they happened to be facing at that moment). Playing the soup game involved freely moving about until an outside leader called out a rule that was then instantly followed. When campers developed rules they had to show players what it meant to follow it. This raised important questions from peers about specificity, asking questions like "How long do we wiggle for?" or "How many steps forward do we take? Are they in a certain direction?" These calls for specificity exemplify the role that double awareness played in the campers' understanding of both activities--writing and interpreting code as well as choreographing and being choreographed for. These noticings stemmed from students taking the perspective of what they as human agents/dancers would have to enact in the game, while responses took into account what it would mean for an individual to enact a rule and what the group might look like enacting this rule together. As campers played the soup game over the course of the week the complexity of their rules and ability to enact them as an ensemble visibly increased as their double awareness developed and supported their computational fluency.

Through this work we are beginning to understand how an experience of being inside a structure and forming it in relation to others supports new understandings of the structure itself. Based on these findings, we argue dancers' engagement in double awareness can be leveraged for computational learning, supporting students' understandings of the expressive potential of computation.

DanceON: Exploring embodiment in a dance computing learning application

Kayla DesPortes, William Payne and Yoav Bergner, NYU

Computing technology presents opportunities to examine the ways in which data on and about the body can be sensed, represented, and interacted with to support dance practices while also supporting learning about computing. Dance education engages learners with their physical, intellectual, and emotional selves (Bannon, 2010) while providing practices tied to “self-expression and interpretation through motion” (Koff, 2000). Developing learning experiences across computing and dance enables us to examine how we can leverage embodied ways of knowing about the self and computing technology grounded in our understanding of our perceptual representations and bodily states within a social environment (Lawrence, 2008). In this research, we examine how computing technology can be designed for a dance computing educational environment to diversify the embodied ways of knowing and learning.

Prior work at this intersection has examined the potential for learners to leverage knowledge of their bodies as they problem-solve and program virtual avatars (Leonard et al., 2020). For example, Leonard et al.’s work explored the idea of body syntonicity (Papert, 1980) as they identified how some learners approached a challenge of programming a virtual avatar to dance through moving their real bodies and translating the knowledge from physical movement into code (2020). We build on this work exploring opportunities for embodiment in a dance computing tool called danceON (dance Object Notation) (Payne et al., *In Press*).

We developed danceON through a collaborative design-based research investigation (Design Based Research Collective, 2003) consisting of semi-structured interviews and weekly design meetings with STEM From Dance, a community organization that specializes in developing computing experiences for young women of color to expose, interest and engage them in STEM disciplines. The technology was developed in the midst of the COVID-19 pandemic, thus developed in ways that aligned with the need to engage with learners in a remote environment. danceON pairs a declarative, reactive programming environment (Krishnamurthi & Fisler, 2019) with built-in pose detection. The system enables learners to program animations that respond to the pose data of their bodies. These animations are then rendered on top of a coordinate pixel plane of their uploaded video data or webcam footage. Through this integration of body data, the learner’s own movement and position become the subject of most programming statements in danceON. Thus, common programming constructs are embodied and reasoned through with movement. For example, learners can trigger animations based on conditional statements that explicitly describe body positions, e.g. “if my left wrist is in the top left position of the screen”, “if my right knee is above my right hip,” etc. Literature on embodiment suggests the importance of being able to ground the meaning of words and actions into the lived experience of the person (Glenberg, 2008).

We discuss our findings from an analysis of four artifacts created with danceON that encompassed music videos with original choreography and programmed animations, co-developed by learners and instructors within a STEM From Dance summer camp. The artifacts encompassed themes related to girl power, the Black Lives Matter movement, and self-love. We reflect on the ways the code represents how learners were able to explore body position and movement within their creations and examine how computing technology could further support embodied learning experiences and expressivity. Our analysis demonstrates how learners were able to: (1) identify, quantify, and define specific movements and poses; (2) explore mappings of animations to their bodies; (3) augment choreography with animations that represent specific lyrics and visually convey narrative; and (4) experience and overcome the affordances and constraints of computer vision algorithms that occasionally produce missing or inaccurate data.

Abstract: Modeling is generally recognized as the core disciplinary practice of science. Through examinations of rich learning environments which expand the boundaries of modeling and the practices connected to it, researchers are broadening what modeling means in disciplinary settings. This interactive session brings together a diverse spectrum of scholars to share the practices they have used to expand modeling, how they were used in their curriculum, and the impact they had on learning. This session will serve as a rich opportunity for discussion to help advance the state of the field around what counts as modeling and the role it can play in learning.

Motivations and objectives

Since a fundamental objective of science is explaining phenomena through model construction, science educators and researchers have increasingly called for science instruction to be organized around models and modeling. These calls have rightfully emphasized directing learner's conceptual activity towards *disciplinarily accepted* forms of inquiry (Lehrer, 2009). However, more recently, scholars have begun to push on the boundaries of modeling to include learners' everyday practices and funds of knowledge. The papers in this symposium present work that expands what modeling can look like in formal and informal settings by drawing on a range of repertoires of practice including dance and movement (Vogelstein et al; DeLiema et al; Fridman et al), storytelling and drama (Reimers & Brady; Wagh & Dickes), discursive and linguistic resources (Farris et al; Pierson & Brady), and cultural and historical ways of knowing (Lam-Herrera et al). We collectively refer to this line of work as *expansive modeling* - broadening the ways we see value in modeling and the practices that can be connected to it. We see this work as critically important because it expands the field's understanding of what can count as modeling and the role it can play in sense-making thereby making it inclusive of and accessible to a wider range of learners. Themes explored include: (1) the practices which became an integral component of the modeling repertoire, (2) the curricular and methodological decisions taken to expand modeling, and (3) what impact these expanded practices had on learning. The goal of this symposium is to showcase how various efforts approach expansive modeling, its role on learning and to provide a knowledge base to build on and be inspired by.

Session format

To promote active and productive discussion, the symposium will be conducted as an interactive poster session. Following brief teaser introductions on each project, attendees will be invited to view presenters' posters. This will provide attendees ample opportunities to examine and discuss curricular and methodological decisions made by the presenters, and how they may be adapted for attendees' own designs in a way that traditional talks do not allow. The symposium will close with an open discussion, in which the discussant will engage presenters and attendees in discussion around the main themes and any areas of interest that emerge during the session.

Theatrical modeling of planetary systems: Expanding the role of perspective in modeling

Jackson Reimers & Corey Brady

We present results from design-based research investigating the potential of engaging students in embodied activities at the intersection of participatory theater and agent-based modeling, focusing on planetary systems phenomena. We were motivated to see how a group of students might come together to physically constitute a representational infrastructure for modeling that supports dynamic perspectival understandings (Greeno & van de Sande, 2007). We saw this possibility as especially propitious for the study of *planetary systems*, which afford a variety of meaningfully distinct perspectives yet can be captured using a relatively small number of interacting agents. Given these motivations, we drew inspiration from both participatory theater (e.g., *Theatre of the Oppressed* (Boal, 1985)) and agent-based modeling (Wilensky & Rand, 2015) as collaborative, socially distributed structures for engaging participants' perspectives in a sense-making endeavor.

Over six successive implementations of a planetary systems unit, designed and facilitated in partnership with a 5th grade STEM teacher, we explored this rich design space. Analyzing our designs, we have articulated initial principles of *theatrical modeling*. While these principles are still tentative, they suggest the power of theatrical modeling in itself and as an expansive addition to the multi-modal modeling enterprise. We identified activity designs that foster multiple modes of thought, ranging from *subjunctive, "What if?" thinking*, enlisting imagination, to *subjective, "What would it mean?" thinking*, enlisting story. These operate in flexible conjunction with the *objective "What is it?"* or *"How does it work?"* thinking more commonly associated with modeling practices, ultimately broadening what it means to know, ask, claim, and interpret in modeling practice.

In theatrical modeling, the modelers *are* the model. Participants simultaneously enact their understandings about the planetary bodies they represent, while also interpreting each others' enactments in this light. This setting is rich in opportunities for collective ideation, argumentation, contestation, and sense-making. Negotiating both "what we just did" and "how we can improve it" thus calls for coordination across perspectives. Theatrical modeling also blends process and product. The model (as product) is a coordinated performance, a collective action that is both a demonstration and a new occasion for question-posing. Re-enacting the model provokes inevitable variation and new observations. Thus, to instantiate a theatrical *model* is to engage in another round of model*ing*. Furthermore, participants' enactments are *polysemic*—they often express more or different ideas than the participant explicitly intends—and these "surplus" meanings fuel the interpretive work of the group, suggesting possible shifts in target phenomena or uncovering unexpected facets of planetary dynamics. These elements of theatrical modeling offer a new set of affordances and constraints for students' modeling practices. We see this most strongly in light of Goodwin's notion of a substrate for co-operative action (2018). Theatrical modeling engages students in using a broader set of semiotic resources, de-settling academic notions of legitimacy and subverting disciplinary boundaries at the interactional level.

Decolonizing complexity: An axiological reorientationfrom a Mayan perspective

Marilu Lam-Herrera, Women Weavers Community Council of Santo Domingo Xenacoj & Pratim Sengupta

In this research, we illustrate how agent-based modeling of emergent phenomena can be re-imagined through the lens of decolonization by partnering with Indigenous Mayan women weavers, high school teachers, and the Ixkoj Ajkem Council (Women Weavers Community Council) in Xenacoj, Guatemala. Research on complex systems emphasizes the importance of understanding emergent phenomena through building progressively complex relationships among individuals and between individuals and their environments (Dickes, et al., 2016; Wilensky & Resnick, 1999). However, modeling complex systems from embodied and agent-based perspectives can also be synergistic with Indigenous ways and forms of knowing and support interdisciplinarity in ways that value cultural historical forms of knowing (Aikenhead & Mitchel, 2011). Furthermore, partnering with Indigenous communities also call for an axiological reorientation of what forms of knowing are *valued* disciplinarily from the perspective of the community (Bang, 2020).

Through our ongoing partnership, we have been designing Grafemos (Lam-Herrera et al, 2019), a modeling environment for learning about emergence. The Grafemos modeling device is a physical "computer" in the shape of a dodecahedron, with slots for images that are soaked in ink and then imprinted on paper as the device is rolled. The images represent agents and interactions and are based on combinations of traditional Mayan motifs used in weaving practices. Modeling with Grafemos is also a communal activity, in which a small group must participate together, while each participant models from the perspective of a specific element in the system. Methodologically, we have adopted *Methodological Métissage* (Lowan-Trudeau, 2012), which is centered on: a) emphasizing Indigenous practices and traditions such as storytelling and symbolizing, and b) working with the elders and members of the community during all stages of the research. We believe that *Métissage* is foundational to enacting axiological reorientation of Western scientific approaches that largely dominate the Learning Sciences. Using the constant comparative method, we present an analysis of a month-long study in which we worked with six high school teachers and two members of the Ixkoj Ajkem Council in Xenacoj, Guatemala. Meeting 3-4 times a week, we worked together on modeling complex phenomena that the teachers and Council members identified as relevant to their lives as well as to the high school science curricula. We used Grafemos, embodied modeling activities, as well as the ViMAP (Sengupta et al., 2015) block-based programming environment. Data collected included video recordings of each session and participants' work.

Our analysis highlights a) how engaging in each form of modeling supported mid-level (Levy & Wilensky, 2008) and multi-level reasoning (Wilensky & Resnick, 1999), b) the axiological reorientation was evident in the kinds of phenomena (e.g., plastic contamination, systemic violence, etc.) that community members valued as scientific topics relevant to their lives as well as the curriculum, and c) how this axiological reorientation was supported through embodied and multimodal representations beyond the computer, that in turn, were intertwined with cultural forms (e.g., clotheslines and fabric motifs). Overall, our work illustrates how modeling with Grafemos offered a space for *Métissage* by bringing together cultural forms, participatory and embodied learning, as well as agent-based representations of complexity, while the axiological reorientation allowed teachers and community members to center events and concerns in their communities as topics of scientific and computational inquiry.

Storymaking and Storytelling: Exploring the affordances of narrative in computational modeling

Aditi Wagh & Amanda Dickes (equal contribution)

Jerome Bruner (2005; 2010) has argued that narrative, or story, is a uniquely human way of making sense of the world; an avenue to explore "possible worlds" and the vehicle through which we frame accounts of our own experience. In this sense, the act of storymaking and storytelling affords narrators opportunities to connect past, present and "imagined" worlds, and define relationships between seemingly disconnected events (Ochs & Capps, 1996). In this paper, we argue that storytelling and storymaking can provide a rich and meaningful context for theory building in science - particularly when situated within the medium of computational modeling - and potentially transform how students come to see and know in science. In particular, we draw on work that positions stories as "nascent theories" (Ochs et al, 1992) that scaffold and normalize practices such as perspective-taking, critical thinking, and abstraction; practices long argued as crucial components of scientific thinking and knowing.

We identify four narrative discursive practices that we believe can be useful in science learning: (1) Employing figurative language, specifically metaphor, as a tool to illuminate qualities of less understood objects (or natural phenomena) by drawing lines of association between the unknown object and objects that are already understood (Quale, 2002); (2) Considering and reconciling competing perspectives by coordinating between different understandings to identify solutions to confusing and challenging narrative problems (Ochs & Capps, 1996); (3) Identifying and contextualizing narrative problems along a temporal dimension to construct a theory of events for how and why problems emerge and how they might impact future events (Ochs & Capps, 1996); and (4) Constructing collaborative meaning through co-authorship, interpretation, and multiple retellings of narrative events. We see these practices as congruent and complementary with the practice of modeling in science and conjecture that the inclusion of narrative as a parallel practice in investigations of natural systems can scaffold learners' use and interpretation of computational models which represent those systems.

In this session, we report on a pilot design study which follows a group of upper elementary grade students' explorations of an invasive species and its impact on local species within the Gulf of Maine through parallel storymaking, storytelling and computational modeling activity. Our analysis describes how students drew on narrative practices, such as temporal fluidity and metaphor, to cohere the disparate elements of the natural system into a "plot" comprising character and conflict, and the role that this narrative work played in supporting their work on modeling that same system. Finally, we discuss the tensions that arose between employment of a narrative frame and more normative scientific frames, and how those tensions were reconciled.

Expansive embodied modeling: Inviting and leveraging students' ideas and linguistic resources

Ashlyn Pierson & Corey Brady

Computational modeling is a powerful tool for helping K-12 students explore and learn about complex systems (Dickes et al., 2013; Sengupta et al., 2013; Wilensky & Reisman, 2006). Yet due to barriers arising both from the syntax and concepts of computational representations, computational thinking and modeling can be challenging for both students and teachers. In response, researchers have worked to design programming environments and learning activities that make computational modeling more accessible. One such approach to support computational modeling is embodiment or enactment. In an embodied model, students role-play agents in a system (e.g., plants and animals in an ecosystem) to explore agent actions and interactions as well as system-level, emergent phenomena from the perspective of these agents (Danish, 2014; Forrester, 1961). To enact agents, students typically follow rules, which are sometimes framed as the "code" or "program" for the agents in the embodied model.

In addition to these affordances of embodied modeling, we propose that embodied modeling activities could be designed to invite and leverage students' linguistic resources and multimodal representations, in turn supporting learning and participation particularly for students classified as English Learners (ELs). Research in bilingual education and science education shows that multilingual students benefit from deploying their full range of meaning-making resources in classrooms (García & Kleyn, 2006), including linguistic resources as well as other semiotic resources (nonlinguistic modes, like images, gestures, actions, symbols; Blackledge & Crease, 2017; Li, 2018). Building upon this work, we explored how embodied modeling activities could be enriched with additional representations beyond embodied actions, including both canonical representational forms (e.g., Cartesian graphs) and students' everyday resources (e.g., gestures, student-generated language), along with social interactions.

In the context of an iterative design-based research project in a 6th grade STEM classroom studying ecosystems and population dynamics, we explore how embodied modeling can expand opportunities for participation and for learning about complex systems. We illustrate how embodied modeling activities were refined with each cycle of our design to offer students distinct ways of understanding their computational models and the ecosystems they represented. We describe three iterations of the design, which positioned embodied modeling successively as: (1) a rehearsal for the computational model, in which each students' unique contributions and perspectives were essential for shared meaning-making, (2) a space for active and collective modeling, as students "remixed" (modified) the code to test their own ideas, and (3) a full-fledged component of the classroom's system of models of ecological phenomena, supported by linked representations drawn from their computational models and from students' everyday linguistic resources. We argue that these approaches to augmenting embodied modeling show promise for supporting participation and complex systems learning, particularly for students classified as ELs.

Meadow bees, hive bees, and a moving sun: Tensions and affordances in learning between embodied point of view and spatial frames of reference

David DeLiema, Noel Enyedy, Joshua Danish, & Francis Steen

A robust educational research literature around complex systems documents how reasoning about systems involves a delicate act of balance between agent perspectives (e.g., viewing the scene from the perspective of one component) and aggregate perspectives (e.g., pulling back to see patterns among multiple components) (Wilensky & Reisman, 2006). Even with third-person, cartesian graphs in mathematics, students might spontaneously embody in gesture the first-person viewpoint of a graphed component (Nemirovsky & Monk, 2000). More recently, with augmented reality technologies that track and display full body movement (Danish et al., 2020), the dynamic of being multiple components in a model all while tracking aggregate connections creates a public process of *coordinating point of view and spatial reasoning*.

Building on a case study of the friction that arises during this coordination process (DeLiema & Steen, 2014), we examine the Science through Technology Enhanced Play's (STEP) unit on bees to document how 1^{st} and 2^{nd} graders and their experienced teacher navigate multiple points of view (bees in the hive; bees in the meadow) and spatial reasoning (bee waggle dance identifying location of valuable flowers). To anchor our multimodal interaction analysis, we draw on gesture research around character and observer *points of view* (Stec, 2012), the notion of layered or *laminated* semiotic resources in interaction (Goodwin, 2018), and *spatial frame of reference* terms such as figures, anchors, and grounds (Levinson, 1996). We strategically selected one video-recorded episode from the six-session unit in which the teacher and two students encounter spatial (in)congruence at the intersection of multiple points of view in order to investigate how participants *notice* this tension between viewpoints within a system and how they *publicly draw on* embodied, material, and interactional resources to resolve the tension.

The analysis documents why material infrastructure (e.g., a flower icon on the floor) that grounds imaginative play across points of view at once *confounds* (e.g., a bee in the hive could never presently see a meadow flower) and *supports* (e.g., a meadow bee can now see it would not arrive at a flower) complex systems reasoning. In addition, the analysis examines how the participants' public efforts to make spatial anchors and grounds more explicit surfaces friction between viewpoint and spatial reasoning, and then become the very resource that clarifies the participants' inquiries (e.g., the bee's "diagonal to the left" flight starts "*from there*"). These clarifying moves laminate gesture, full body movement, talk, and material and imagined objects in sequences of conversational repair to help the participants converge on their understanding of the system. This analysis raises key considerations for designers of material and embodied spaces in which students move across roles or viewpoints in the setting. Most importantly, the analysis shows that tensions between spatial reasoning and viewpoint are not a deficit, but rather, an inherent part of modeling that participants can notice, argue about, and clarify to arrive at a shared understanding of the system.

The collective and discursive nature of model-based reasoning: Discussion as means for thinking together in preservice professional learning and elementary mathematics education

Amy Voss Farris, Rachel Wolkenhauer, Gwendolyn Lloyd, & P. Karen Murphy

Engaging in model-based reasoning is fundamentally interdependent with generating explanations that are justifiable and critiqued by others. Models are a type of purposeful explanation of some phenomenon or process and make reasoning evident by way of letting one thing "stand in" for something else (Lehrer & Schauble, 2010). However, what counts as acceptable forms of evidence and reasoning in particular disciplines is often not made explicit to educators or to students (Manz et al., 2020). Our focus in this poster is on how teacher educators and preservice teachers (PSTs) engaged in discussion-based pedagogy to support authentic forms of questioning and argumentation in three cross-disciplinary contexts: (1) a course called Classroom Learning Environments, which focuses on teachers' inquiry and equitable pedagogical praxis in contexts of complex social and political discourses, (2) a methods course for elementary mathematics, and (3) PSTs' facilitation of mathematics discussions with children in their field classrooms. We argue that explicit attention to questioning and argumentation in discussion-based pedagogy across disciplines supported PSTs' early facilitation of mathematics discussions in their field placements.

We partnered with teacher educators within the Penn State Professional Development School (PDS) to adapt and enact the *Quality Talk* discussion approach. Quality Talk is a small-group, teacher-facilitated discussion approach that has been shown to foster K-12 students' reasoning and content-area learning (Murphy & Firetto, 2017). Teacher educators learned to use Quality Talk discussions to support preservice teachers (PSTs) in methods coursework so that, in turn, PSTs can use the approach in discussions about pedagogy and mathematics and while teaching mathematics in their field experiences. Expectations included eliciting student-generated questions about mathematics, student-initiated responses to peers' questions that include evidence or mathematical reasoning, and collective sensemaking about mathematical tasks. The authors and other PDS school- and university-based TEs co-developed and integrated five discourse lessons and related discussions in the Classroom Learning Environments (CLE) course and methods for teaching mathematics course during the Fall 2019 semester. A series of assignments supported PSTs in preparing to facilitate small group mathematical discussions with elementary students.

Our poster will provide an overview of how teacher educators learned to support PSTs' development of pedagogies for elementary students' mathematical argumentation within the Quality Talk small group discussion approach and offer an illustrative discourse analysis of a discussion with second grade students that was facilitated by one PST, named Laura. In this discussion, Laura demonstrates command of discourse features she learned in her CLE course and operationalized her belief that students, positioned with interpretive authority concerning the task, the mathematical concepts, and one another's ideas, can productively learn together. Within the discussion, the students solve a novel mathematics problem by discursively modeling a problem context in which the cost of green beans is a rate per unit length. They question their own problem representations when one student proposes subtraction as a way to solve the problem. The case illustrates productive connections between learning about discussion-based pedagogy in preservice teacher education and novice teachers' preparation to support critical-analytic discourse in an elementary mathematics task.

From social and embodied modeling to computational modeling in the "Computational Modeling in Science" (CMS) project

Chani Fridman, Sharona T. Levy, & Hagit Hel-Or

The CMS approach to scientific modeling in schools expands the scope of computational modeling to include embodied & social modeling. Embodied & social role-playing activities have the students represent entities in a system by physically moving about the classroom and interacting with other students and objects. This expansion of computational modeling is based on a number of principles: (1) role-playing simulations, which are familiar to teachers', provide a natural bridge into computational modeling (McSharry & Jones, 2000); (2) enabling students to ground scientific and computational abstractions in their bodies and movement, as described by embodied learning theory (Lindgren & Johnson-Glenberg, 2013); (3) having students communicate their ideas in social co-dependent participatory simulations can be a highly effective form of learning (Levy, 2017); (4) providing students with multiple access points into scientific modeling making modeling more inclusive.

The research was structured as a quasi-experimental pretest-intervention-posttest design with a comparison group. The topic of the learning unit included Kinetic Molecular Theory (KMT) and Gas Laws, along with several other related phenomena. First, teacher-led embodied-social modeling occurred with students enacting the rules of particles in a system. Next, similar student-led modeling had students suggesting questions, creating and exploring their embodied model. Finally, students engaged in computational modeling with the Much.Matter.in.Motion (MMM) platform (Levy, Saba & Hel-Or, 2020), which enables modeling many physics- and chemistry-based phenomena. The rules underlying particle behaviors, such as "change direction when you collide", are elicited in these simulations and are later presented as computational blocks in the model coding environment.

In terms of overall learning, there was no difference between the experimental and control groups, both showing increased knowledge on the topics; however, concepts related to the micro-level were learned better by the experimental group. Students' confidence in their answers increased in the experimental group, while they did not do so for the students in the comparison group. An analysis of the students' pictures of perfume spreading in the air showed three types of depictions, successively increasing in sophistication; the analysis showed that the experimental group, but not the comparison group, advanced from pretest to posttest in the sophistication of their understanding of gas behavior. Analysis of the classroom embodied simulations and computational models showed two themes: (1) a close relationship between ideas expressed at the beginning of the learning and the embodied social simulations, and (2) confusions between micro-and macro-levels were gradually resolved along the learning unit. We summarize that the approach we have developed does not show a significant advantage over normative learning when looking at the students' overall conceptual understanding scores. However, when detailed concepts were considered, it was found that the micro-level concepts relating to KMT were learned significantly better with the CMS activities. The students also grew more confident in their answers through the activities, an important feature that may contribute to students' perceived self-efficacy. We conjecture that the embodied social simulation provides a window into students' thinking as they enact their ideas dynamically with their bodies, and also provides the feedback necessary for helping them revise non-scientific concepts.

Flares in the soup game: Improvisational collective choreography and computational expressivity

Lauren Vogelstein, Corey Brady, Rebecca Steinberg, & Curtis Thomas

We share our design and analysis of an activity called "The Soup Game" for a middle school camp integrating computation, mathematics, and art ("Action Camp"). The activity leveraged embodied sensemaking to provide entry points for conceptualizing agent-based programming as a creative performance space. By iteratively proposing and enacting choreographic elements together, student participants constructed, interpreted, and executed sequences of movement they later expressed computationally in NetLogo (Wilensky, 1999), eventually orchestrating hybrid human-computer performances. To study students' embodied ideation processes, we look specifically at *flares*, movements that spread through regions of the group as they developed and enacted choreographic rules. We argue that flares offer one form of evidence of creative group-level thinking.

We identified connections across our diverse research and teaching experiences, in themes of exploring the expressive potential of groups (Vogelstein, 2020) and engaging young learners to position themselves as *creators* of valued works, whether in the domain of dance, mathematics, or computational thinking. We came to see many similarities between creating movement scores for people to perform and writing code for agents ("turtles") to perform. Steinberg & Thomas brought the seed of The Soup Game from activities they had used to give dance students opportunities (a) to experience how simple rules can generate complex choreographies, and

(b) to practice using their voice as leaders in creative collaboration. In the game, groups devised and named movement rules (e.g., “craziness” meant “spread out while always moving”) that would later be called out to form performance scores. Bridging to computation, we leveraged parallels between movement rules and computational procedures; and we connected the *leader* calling out named rules to NetLogo’s *observer* communicating commands to turtles. Our design also built on research showing the power of *syntonic learning* (e.g., “playing turtle,” (Papert, 1980)), and group role play (e.g. participatory simulations, (Brady et al, 2016)).

We focus on the spread of movement ideas when campers jointly created movement rules and worked out how to enact them. Video recordings from multiple camera angles captured different perspectives on the activity (Hall, 2000). We augmented Interaction Analysis (Hall & Stevens, 2015) with newer, embodied forms of reenactment and analysis (Vogelstein et al., 2019), which we also extended. We found that participants often interpreted others’ movements as invitations to move, themselves—as *proposals* to respond to (cf., Vogelstein, 2020). Movements spread as flares within regions of the participant group when generating rules. Flares served to clarify and extend emerging choreographic elements in *shape*, *space*, and *time*—physically performing ideas, and observing others, afforded new noticings (Kirsh, 2010). Flares also revealed compositionally rich possibilities that *stretched the meanings* of rules. We show how flares provide evidence of collective sensemaking: physical proposals and responses allowed the group to explore its expressive potential and the enacted meanings of commands they generated.

Abstract: The global COVID-19 pandemic outbreak has put front and center the need for learning and teaching about epidemics, as the participation and actions of all citizens are critical in containing and preventing the spread. In this symposium we are presenting current, on-going research on learning and teaching about infectious diseases that examines (1) K-12 students' understanding of infectious diseases such as COVID-19, (2) family interactions around making sense of COVID-related science information, (3) game designs to address COVID misconceptions, (4) computational modeling tools to help students understand disease vectors, and (5) virtual epidemics to provide students with online experiences about disease spread and prevention. Panelists will present findings from their on-going studies and discuss what research directions learning sciences can take to promote health literacies for teachers, students, their families and communities. Our discussant will review overarching themes then open up the panel to Q&A.

Keywords: COVID-19, K-12 digital learning, educational technology, gamification, epidemiology

COVID-19 follows a flurry of previous infectious disease outbreaks—such as Avian Flu, Ebola, MERS, SARS, and Zika—revealing the threat that epidemics pose in the age of global travel. While much attention in the current COVD-19 pandemic has focused on schools' move to online education, in particular highlighting the lack of access and challenges in home learning, much less attention has been given to what teachers, students, and families need to know about infectious diseases and their prevention. Learning about infectious diseases is not even explicitly addressed in current national science standards guidelines in the United States (NGSS, 2013) and for that reason has received little attention in current K-12 science education and research. Infectious disease epidemiology (Straif-Bourgeois, Ratard & Kretzschmar, 2014) includes an understanding of not only of biological concepts such as germs and infection, but also of processes such as incubation and immunity within larger ecological contexts and, most importantly, of community factors that contribute to or hinder epidemic outbreaks. This need has become so urgent that a call for a "microbial literacy" (Timmis et al., 2020) has been issued and this is where K-12 learning sciences research can make a critical contribution.

This symposium brings together researchers from different fields in the learning sciences (i.e., science education, psychology, game studies, and computer science) who began studies in the midst of and motivated by the COVID-19 outbreak. A first group of presentations will examine different facets of students and their families' understanding of infectious disease epidemiology. While K-12 students' basic biological understanding of what happens with germs in their bodies expands with age, they struggle to comprehend the interconnected nature of epidemiologic spread on an ecosystem level. Concepts such as incubation, infectious, and symptomatic periods of an infectious disease are not well understood . We will also examine what roles families and caretakers play in promoting understanding, often serving as the first point of contact for children about this information (e.g., Jones and Rua, 2009; Toyama, 2019). Little is known about how family members negotiate such understanding, what kind of conversations take place, or how scientific information promoted in social media and news is approached .

A second group of presentations will focus on students' learning about infectious disease epidemiology. While textbook studies of historical cases about infectious diseases and epidemic outbreaks have been a mainstay in science education, in the last two decades digital games, epidemic simulations, and participatory virtual epidemics have been added to the instructional repertoire (Kafai & Dede, 2014; Wilensky & Rand, 2015). We will discuss how these technological tools engage students with critical aspects of infectious disease epidemiology, how teachers have used these tools in their classes, and how students make connections between virtual and real epidemics.

Each of the presenting teams will address critical questions about understanding and learning about infectious disease: *What are students' beliefs about different aspects of infectious disease epidemiology? How and what science do people learn about COVID-19, when they may have little to no science preparation or previous interest in the topic? How do students' interactions with games, simulations and virtual epidemics promote better understanding of critical aspects of infectious disease epidemiology? What unique barriers and opportunities exist for learners approaching infectious disease subjects for the first time while simultaneously experiencing the COVID-19 pandemic?* Each team will present updates from their on-going research with teachers, students, and families. Our discussant, Jim Slotta from University of Toronto, will review overarching themes and then open up the panel to Q&A with the audience.

Learning rapidly: Youth data activism in the 2020 multi-pandemic

Angela Calabrese Barton, Day Greenberg, Chandler Turner, Za'Mani Roper, Carmen Turner, Devon Riter, Leslie Herrenkohl, Elizabeth A. Davis, Tammy Tasker

Through long-term research-practice partnerships (RPPs) in the midwestern and western US, we sought to understand what/how community partners learn about and take action on COVID-19 and justice-related concerns. In this study, we investigated how minoritized youth engage in data activism in relation to their meaning making around COVID-19 and its intersections with economic and racial injustice. We define data activism as social practices that take a critical approach to "big data" (Milan & Velden, 2016), in response to justice-related concerns of pandemic datafication. As datafication introduces new challenges of representation and positioning of people and the world, we give witness to youth resisting, disrupting, and transforming such challenges during/through innovative digital navigations of crisis events (Goldkind et al., 2018).

We draw upon theories of digital agency and youth data activism as forms of consequential learning through critical social practice within communities (Milan & Velden, 2016). Consequential learning focuses on what counts as valued learning, and how processes of learning can disrupt or transform normative patterns of participation towards new and just forms of expertise and social relations (Gutierrez et al., 2017; Jurow & Shea, 2015).

Using a historicized and future-oriented participatory methodological approach, we give witness to and learn with youth and community. We center youth voices, placing importance on open-ended methods with co-determined protocols, co-analyzed findings, and co-written manuscripts. To attend to power in our remote methods, we further drew upon practices of critical witnessing and being with—practices toward conscientization, social transformation and the public good of communities historically marginalized by systemic inequities. We seek to amplify possibilities for coalition building and learning in "daily, (extra)ordinary, and intentional" work (Villenas, 2019, p. 153). Since late-March 2020, we engaged in multiple rounds of dialogic critical ethnographic conversations and experience sampling methods with 62 participants (20 adults & 42 youth/young adults) in two urban communities with whom we have long-term collaborations. Dialogic conversations (60-240 minutes/participant/round) focused on: COVID-19 information accessed/applied towards decision-making, and how/why; how efforts were situated within personal/community COVID-19 experiences/networks. Data were co-analyzed with participants using critical inquiry in a constant comparative, continuities and contradictions approach (Charmaz, 2017).

Youths' enactment of critical data practices shaped how they negotiated between coming-to-know and coming-to-act in the multi-pandemic. We operationalize c*ommunity-engaged critical practices* as what people do in socially-mediated and culturally-embedded ways with, in relation to, and oriented around data and data infrastructures in support of more equitable everyday living and communities. These practices arose from tensions in the youth's engagement with data as they mobilized big and small data from different epistemological and social origins towards meaning-making, action-taking and communicating. These tensions shaped how and why youth: *Re-mixed data practices* and authored new hybrid ones for socially/critically navigating, understanding and repurposing data into/of their worlds; *Critiqued and recontextualized data and data narratives* for re-imagining data about their worlds and hoped-for-futures; and *Re-positioned oneself and one's world into data*. For example, Jazmyn, used social media apps as a gateway to the CDC's COVID-19 databases. She paid attention to posts where the individuals looked like her and were posted from verified science-related accounts. She participated in her city's racial justice protests wearing a mask and social distancing after a complex analytical process of weighing different data inputs such as comparative efficacy of risk mitigation behaviors, patterns of infection/spread in her region, predicted numbers of participants, and photos of other recent protests to gauge how many participants looked like they took safety precautions.

Elementary school children's beliefs about viral transmission of COVID-19 and the common cold

Danielle Labotka, Sophie R. Martel, Susan A. Gelman

In the COVID-19 crisis, effective means of educating children about disease transmission is paramount. Contrary to earlier reports, evidence suggests school-age children can contract and spread COVID-19 (e.g., Szablewski et al., 2020). Children often play a role in viral transmission, given how frequently they put things in their mouths, touch their faces, etc. Public health recommendations include teaching children best practices (e.g., hand-washing) to reduce transmission, yet research indicates children are unlikely to engage in these practices without understanding the mechanisms underpinning transmission processes. Understanding COVID-19 transmission is particularly challenging, given many non-obvious transmission factors like asymptomatic carriers, long incubation periods, and seemingly innocuous transmission behaviors (e.g., singing). This talk reports on a study of children's and adults' understanding of COVID-19 transmission (and the common cold, as comparison), with a comprehensive, cross-age assessment with U.S. families.

We developed a survey with 40 close-ended and 13 open-ended questions to assess four components: (1) understanding that viral transmission processes are non-obvious; (2) knowledge that viruses are quasi-living agents that operate via certain biological processes (e.g., can replicate); (3) how coherent understanding of transmission processes relates to biological beliefs; and (4) how beliefs regarding COVID-19 compare to those of the common cold.

Study 1 (N=240, completed, pre-registered) tested a national sample of adults via an online survey. Analyses are ongoing. Preliminary results indicate adults generally have basic knowledge of COVID-19 transmission (e.g., transmissibility; incubation period), but there is variability in understandings of the underlying mechanisms by which viruses operate. Whereas some adults have a biologically coherent understanding of viruses—discussing viruses as requiring a host, reproducing, and evoking immune system responses—others have vaguer understandings (e.g., “It takes time to do whatever it does to make you sick”), refer to viruses as bacteria, or report that viruses eat, grow, and move.

Study 2 (projected N=160, current N=146, pre-registered) investigates the same questions as Study 1 in a child-friendly format. Children (5-12 years old) are interviewed via video conferencing. Interviews are recorded, transcribed, and coded. Initial testing indicates children may recognize some non-obvious features of COVID-19 transmission (e.g., asymptomatic carriers) at lower rates than adults. Furthermore, preliminary evidence suggests children may overbiologize viruses, often reporting they can grow and move on their own. This tendency to overbiologize may influence children’s understanding of viral transmission, with some children describing viruses as tiny creatures that “crawl” around and anthropomorphizing viruses by assigning them agency, character, and desire. Intercorrelations among children's performance across tasks will assess whether understanding consists of piecemeal facts vs. coherent understandings.

Findings from the project will provide information regarding gaps and misconceptions in children's understanding of the transmission of COVID-19 and viruses more generally, providing data on how to target efforts to improve children’s scientific literacy and adherence to public health guidelines. It will also provide theoretically significant data relevant to STEM education regarding the coherence of children's biological theories over development, and children's informal biological theories in the context of an ongoing pandemic.

Applying gamification to correct COVID-19 misconceptions among the general public

Greg Trevors, Eric Brenner, Cierra Chong, Danielle Graham, Justin Kogler, Farhaan Ladhani, Kevin Melo, Ornab Momin, Jordan Morello, Tanya Whyte, Sean Willett, Kara Wilson Oliver, Ben Windeler, Sam Wollenberg

Compounding the public health challenges posed by the COVID-19 pandemic is an *infodemic* of misinformation regarding risks, prevention, and treatments (WHO, 2020), which may lead to serious and irreversible harm to individuals and communities. However, several prior attempts to refute misconceptions about controversial or emotionally laden topics like COVID-19 have failed (Trevors & Duffy, 2020). Refutation failures may undermine important collective actions needed in a pandemic, such as vaccine-acquired immunity. This study leveraged unique strengths of cognitive research on belief change and design principles of gamification to develop a new digital game to correct COVID-19 misconceptions to overcome specific limitations of direct refutations.

From May-June 2020, 19,493 Canadian participants were recruited to engage with a non-game control version of the online platform, which contained 13 content pages that presented one fact or misconception about COVID-19 (e.g., “COVID-19 has caused fewer deaths than the flu (influenza) would typically cause in a year”). Participants swiped left or right to indicate their agreement or disagreement with the claim. The following screen presented immediate feedback that followed evidence-based practices for belief revision (Trevors & Kendeou, 2020). Following feedback, participants reported their emotional reactions to the content (i.e., happy, angry, anxious, or skeptical). From August-November 2020, 67,072 participants played the gamified platform (Figure 1), which contained 12 of the original 13 claims plus 11 new claims. Overall, the digital game was designed to motivate and positively engage learners as they processed corrective feedback via game elements and mechanics (e.g., challenge, personalized experience, visible progress). In both control and gamified versions, participants also reported their support for public health policies (e.g., wearing masks in public) and in the gamified platform, their personal willingness to receive a COVID-19 vaccine when one becomes available.

Figure 1. Screenshots of digital game.

In separate regressions, beyond the effects of prior knowledge (i.e., number of claims answered correctly), happiness and anxiety were positive predictors of public health policy support ($\beta_{hap} = .115$ / $\beta_{anx} = .074$) and vaccine uptake intention ($\beta_{hap} = .116$ / $\beta_{anx} = .075$), whereas anger and skepticism were negative predictors of policy support ($\beta_{ang} = -.049$ / $\beta_{skp} = -.183$) and vaccine intention ($\beta_{ang} = -.034$ / $\beta_{skp} = -.201$). Happiness and anxiety were higher and anger and skepticism lower in the game version compared to the control (p's < .0001, d's = .049-.201), which held true even after controlling for prior knowledge.

The current proposal represents a new digital approach to misconception correction that may augment how individuals cognitively and affectively interact with challenging educational content and may overcome limitations of prior direct routes of science communication. We found that positive and negative emotional reactions to corrective feedback were significant predictors of subsequent policy support and vaccine uptake intention beyond the large effect of prior knowledge. This supports our central contention that increasing positive and decreasing negative affective engagement of belief correction content via gamification may be important and opposite drivers of promoting acceptance of controversial socio-scientific content.

A block-based modeling curriculum for teaching middle grade science students about COVID-19

Veronica Catete, Madeline Hinckle, Tiffany Barnes, and Eric Wiebe

The COVID-19 pandemic has amplified the critical need for science literacy for an informed citizenry. As with all public health crises, the lack of a strong consensus around an actionable scientific model has led to unnecessary suffering and death. Now more than ever, it is crucial to provide students with factual information about how diseases spread and how their own actions can impact that spread. Computational modeling provides an excellent vehicle for raising scientific awareness of the emergent understanding of COVID-19. In order to both encourage computational thinking (CT) skills and build scientific knowledge of the COVID-19 pandemic, we have created a series of programming activities through which students construct their own computational models based on the emerging scientific consensus around COVID-19.

This unit was adopted from a unit on epidemic modeling developed as part of an NSF-funded CT integration project (Cateté et al., 2018; Lytle et al., 2019). The models utilize an agent-based modeling approach (Wilensky & Rand, 2015) where a conceptual scientific model is re-represented by students as an interactive block-based simulation of the interaction of agent-people who are in various physiological states. Students are able to model everyday situations such as being in a crowded area or going to stores while unknowingly infected, and immediately see the consequences of those actions. Students can explore the differences in direct versus indirect transmission, as well as symptom severity, and their effects on the model outcomes. By including accurate scientific variables such as the reproductive number of the virus, incubation period, and period of communicability, students are able to create their own epi-curves that demonstrate the severity of the disease and provide students with visual representation of how quickly COVID-19 spreads. We also use the scientific model and associated modeling activities to reinforce best practices at home and in the community.

Teachers involved in the development of the original epidemic modeling unit also reviewed the COVID-19 units and indicated their promise for use in middle grades science classrooms. Pilot testing of the units is underway with anecdotal evidence sparking new questions about balancing students' inquiry and play with understanding the gravity of certain topics. We will use the CEO model (Lytle et al., 2019b) to evaluate the materials in formal classroom settings during the epidemics science unit and will compare the data to our past flu-themed implementations regarding engagement and understanding.

Virtual epidemics for promoting students’ immersion and inquiry into pandemic outbreaks

Yasmin Kafai, Deborah Fields, Colby Tofel-Grehl, Michael Giang, Jen Sun, Amanda Strawhacker, and Tyler Hansen

Investigating middle-school students’ understanding of infectious disease in the context of a virtual epidemic connects youths’ interests in socializing online with modeling approaches promoted in professional epidemiology. Our approach builds on two prior studies that investigated the outbreak of virtual epidemics called WhyPox and Dragon Swooping Cough in Whyville.net, a virtual world with millions of registered players. The virtual epidemic affected two key aspects of online players’ social lives: (1) *appearance,* in which dots or scales would appear on players’ avatars, intensifying and then receding as the disease faded away, and (2) chat *interactions* consisting of the random interruption of chats with an “Achoo.” Key findings from these two previous virtual epidemic studies with thousands of online participants revealed that the virtual epidemics not only promoted science talk (Kafai & Fields, 2013) and argumentation practices (Kafai & Wong, 2008) but also strongly affected players’ physical and social actions in the virtual world (see Kafai et al., 2007; Fields et al., 2017) including increased preventive behaviors.

Figure 2. (a) Whyville players with personal protective equipment, and (b) Whyville CDC testing site.

In designing SPIKEY-20, we modeled a respiratory disease outbreak similar to COVID-19 but with an important distinction: SPIKEY-20 caused no deaths. Infected players were covered with spikes during the symptomatic period, with coughs, shaking, and lack of salary for the three most severe days of infection. Further, there was a period of non-symptomatic contagion and options to prevent the disease through behavior (e.g., covering their mouth prior to coughing) and by wearing personal protective equipment (e.g., face masks and full body "bubbles") (see Figure 2a and b). In addition, players have access to unlimited, free testing (with false positives and negatives, see Figure 2b) as well as a community infection graph (see Figure 3a) with daily updates. Players can use epidemic simulators (see Figure 3b) for testing different disease vector configurations. The initial launch of SPIKEY-20 in October 2020 resulted in a full-fledged outbreak. We collected logfiles of online interactions before, during, and after the SPIKEY-20 outbreak as well as pre- and post-surveys from over 300 players.

Our investigation of player participation in the virtual epidemic SPIKEY-20 relates to critical aspects of infectious disease epidemiology (Straif-Bourgeois, Ratard & Kretzschmar, 2014), in particular students' understanding of processes such as incubation and immunity within larger ecological contexts and, most importantly, community factors that contribute to or hinder an epidemic outbreak. Using logfile data, we looked at changes in (1) *Engagement with information*: players increased their visits to Whyville's virtual Center for Disease Control, community infection graphs, and information pages (see Figure 3a); (2) *Use of epidemic simulators*: We found that both the frequency and systematic usage of simulator use increased *among classroom participants* (not the general population) during the SPIKEY-20 outbreak (see Figure 3b); and (3) *Preventive behaviors:* The SPIKEY-20 epidemic outbreak resulted in increased use of protective measures and preventive actions (e.g., handwashing, using protective equipment, and getting tested for the virus repeatedly).

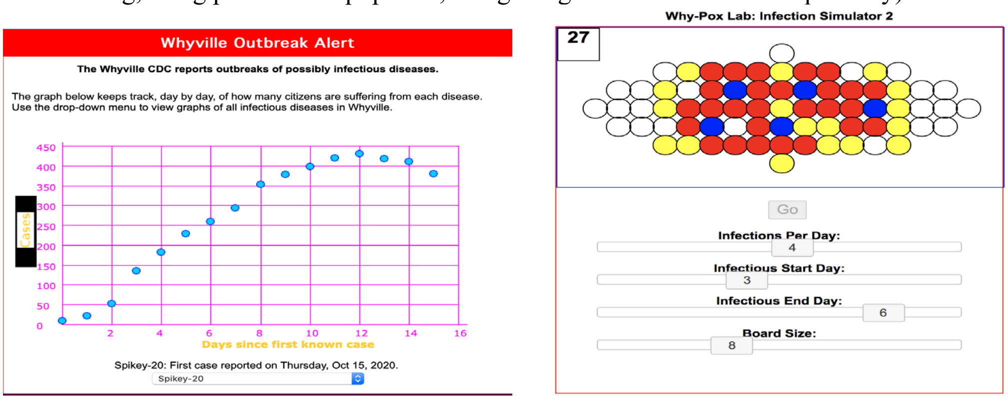

Figure 3. (a) Community infection graph, and (b) Small-scale epidemic simulator within Whyville.net.

Our analysis also includes survey results that connect actual online behaviors with self-reported behaviors and knowledge of real infectious diseases. Analysis of select high school classroom student writings complement our analyses and provide context for actions and comparisons students made between real life experiences of COVID-19 and virtual experiences with SPIKEY-20. These initial observations help us understand patterns of participation and engagement in virtual worlds, and how the educational opportunities for learning about infectious disease offered in Whyville could be further enriched if combined with instructional guidance from science teachers.

Abstract: This symposium explores the empirical relationship between two theoretically distinct uses of the construct of *positioning* in the learning sciences. To do so, it brings together different studies that examine teaching and learning in STEM classrooms that incorporate both embodied and social aspects of positioning. These examples contribute to answering the question: How does simultaneously considering students' and teachers' embodied movements and social positioning offer new insights into studies of STEM classroom learning? Together, these studies show how different types of positioning are tightly related to one another, suggesting that more research is needed to understand the complex relationships between the physical, social, and epistemic positions in research and design of learning environments.

Introduction

Research in the learning sciences has used the construct of *positioning* in a variety of forms to understand teaching and learning in classrooms, often using theoretical perspectives of individual cognition or the sociocultural practices of the classroom community (Cobb & Bowers, 1999). Two common uses of the construct of positioning include embodied cognition, which foregrounds the individual cognition perspective, and social positioning, which foregrounds the sociocultural perspective. Research on these different forms of positioning has previously been separate from one another, taking up one perspective or the other.

Embodied cognition theorizes that human reasoning, no matter how abstract, is ultimately rooted in sensorimotor experience. Past research in this tradition highlights the role of *physical* positioning in teaching and learning. Findings in this area suggest that bodily movement is often inextricably linked to understanding and communicating concepts in algebra (Walkoe, 2015), geometry (Roth & Thom, 2009), chemistry (Flood et al., 2015), and physics (Lindgren et al., 2016), among others. Currently, researchers are using the principle of embodiment to design novel activities that promote mathematical (e.g., Abrahamson et al., 2020) and scientific learning and engagement (e.g., Danish et al., 2020; Lindgren et al., 2016).

In contrast, research on social positioning situates learning as occurring within the context of complex social and interactional dynamics of a classroom. Research from this tradition takes up the idea of positioning *metaphorically* in relation to teaching and learning. As such, this research investigates teachers' and students' social and epistemic roles in interaction in terms of framing, identity, authority, agency, and power. Researchers using this lens have found that opportunities for student learning in STEM classrooms may be afforded by curricular design through redistributed epistemic agency (Ko & Krist, 2019) or constrained by social and epistemic authority assumed by teacher and peers (Langer-Osuna, 2016).

While each perspective offers distinctive views of learning, the notion of position, both physically and metaphorically, is central to embodied cognition and social positioning research. Education researchers have begun to ask questions across these traditions while investigating teaching and learning in K-12 STEM classrooms. For instance, how might a teacher's physical position and movement within the classroom space contribute to shifts in the epistemic framing of tasks? (Kelly, 2020). However, research that meaningfully integrates positioning across cognitive and sociocultural theoretical perspectives remains rare. We argue that this integration is important for understanding and designing for learning in STEM classroom environments that account for these connected aspects of positioning.

This symposium brings together research on learning and teaching in STEM classrooms that investigates positioning by integrating multiple perspectives. Collectively, we acknowledge embodied aspects of thinking and acting, while also recognizing the role of interaction in teaching and learning. Individually, we each offer a unique way in which we bring together notions of embodiment and social positioning through theoretical framing and methodological considerations. The session will begin with introductory remarks followed by the presentation of five papers, described below. Then, our Discussants, Dr. Soo-Yean Shim and Dr. Robb Lindgren, will co-lead a discussion around the question: How does simultaneously considering students' and teachers' embodied movements and social positioning offer new insights into studies of STEM classroom learning? Ultimately, this symposium will advance the field of learning sciences by envisioning possibilities for new lines of research that better integrate these distinct traditions through theoretical and methodological bricolage (Cobb, 2007).

Who gets to hold the counting cubes?: Exploring authority relations among peers during collaborative struggles in K-2 mathematics

Jennifer Langer-Osuna, Rosa Chavez, Jim Malamut, Faith Kwon, Emma Gargroetzi, Kimiko Lange, and Jesse Ramirez

Student-led collaborative mathematical activity involves relationships of power. Relational power among peers, such as status (Cohen & Lotan, 1997) and authority (Langer-Osuna, 2011, 2016), can shape not only who participates and in what ways (Wood, 2013), but also the nature of the mathematical discussions (Esmonde & Langer-Osuna, 2013), the construction of a mathematical solution (Kostopoulous, 2014; Langer-Osuna, 2016), and the development of identities as learners (Anderson, 2009; Bishop, 2012). Yet, the study of relational power in peer-led collaborative learning has been relatively small.

The early elementary years is a time of both introduction to schooling and significant changes in children's socio-emotional development. Studies of how young children come to dominate social situations reveal both prosocial and coercive ways they garner influence with peers (Bohart & Stipek, 2001; Hawley, 2002; Ostrov & Guzzo, 2015). Ostrov and Guzzo (2015) found that the most influential children were the ones who readily shared with others and did so in the absence of a teacher directing them to do so. These findings suggest that the construction of influence among peers can both promote or disrupt possibilities for productive and equitable collaborative learning, depending on the strategies deployed. More disruptive forms of domination serve to marginalize peers rather than regulate shared activity (Langer-Osuna, 2011).

The social construction of influence or marginalization in collaborative learning, in particular, can help to illuminate the processes by which students come to build mathematical knowledge, while accounting for issues of equity. We draw on the Influence Framework (Engle, et al., 2014; Langer-Osuna, 2016), which posits that influence arises from the social negotiation of: (a) the conversational floor and (b) interactional space, (c) the perceived merit of ideas and behaviors, and (d) being positioned with authority. We apply this framework to illuminate young learners' relations of power and how they shape collaborative mathematics learning activity. This paper focuses, in particular, on key moments of interactional struggle and makes visible the sources of authority students drew on to influence the actions of their peers.

This study is situated within a broader Research-Practice Partnership between a university research team and an instructional team of five teachers at an elementary school in Northern California that served predominantly bilingual Latinx and Pacific Islander students. The goal of the broader partnership was to support teachers in implementing student-led collaborative mathematical activity, using the Contexts for Learning Mathematics (CFL) instructional units (Fosnot, 2007) as a curricular resource (see Table 1). The teachers involved in the study worked to create classroom contexts in which students were expected to author and evaluate mathematical ideas and to share this authority with one another productively and inclusively.

We focus on a total of 22 videos of student-led table work across three K-2 classrooms (see Table 1). The research team (authors) created analytic content logs of each video at the 5-minute level, focused in particular on describing student talk, bodily orientation and gaze, and distribution of resources. Each video was content logged by two researchers and reviewed by the entire research team in iterative rounds of discussion and development. We then identified all moments of interactional struggle and inductively coded the struggles by type, resulting in the following categories of struggle: students' access to: (a) materials, (b) the conversational floor, and (c) interactional space, as well as struggles around (d) roles and (e) task expectations. We then coded all moments of struggle for (a) their named source (i.e., teacher, other adult, self, peer) and (b) the response to the directives (i.e., taken up, ignored, resisted).

Table 1: Data Sources and Classroom Context by Grade Level

Teacher	Grade	Unit	Number of Videos
Ms. Bene	Kindergarten	Bunk Beds and Apple Boxes	7
Ms. Kim	1st	Bunk Beds and Apple Boxes	10
Mrs. De Waal	2nd	Double Decker Bus	5

Preliminary findings show that drawing on adult sources of authority tended to constrain or dismantle collaboration, while drawing on student sources of authority supported sustained engagement through resolution of interactional struggle. For example, during partner work in a kindergarten classroom, two students were working together when one decided that the other partner should be doing the work, and threatened to tell the teacher that he was behaving inappropriately, resulting in the partner ceasing to participate entirely and folding his body into himself on the desk. In a first grade classroom, one student challenged his partner's authority after a series of slights, to which she responded by singing the lines, "Gonna find out who's naughty and nice," resulting in the student shifting away from the partnership both intellectually and physically. These examples show how students' deployment of adult authority through the perceived threat of getting in trouble can overpower peer resistance and shut down possibilities for shared work. In a second grade small group, one student positioned as slow and hindering completion of the task by his peers consistently resisted his peers' directives by claiming his own competence and right to learn, which sustained his engagement in the task through interactional struggle.

Teachers' awareness of student multimodal thinking

Janet Walkoe and Margaret Walton

Teacher noticing/ teacher responsiveness has been a focus of math and science teacher learning for the past decade (e.g., Sherin, Jacobs, & Phillip, 2011; Robertson, Scherr, & Hammer, 2015). Working to elicit, attend and interpret the disciplinary substance of students' ideas have been identified as important aspects of teaching. Not only do these practices support student inquiry and learning, it is an activity that is productive for teacher learning (e.g., Franke & Kazemi, 2001). The majority of the work on teacher noticing has foregrounded teacher noticing of student's spoken and written ideas. One example is in video club work (e.g., van Es & Sherin, 2008; Walkoe, 2015). Video club PD involve teachers coming together (usually with a facilitator) to discuss classroom video clips. Video clubs have been effective in supporting teacher noticing of student thinking, in particular, because the video allows teachers to discuss a classroom scene. The video allows teachers to watch and discuss a common classroom scene. In the majority of video club work, teachers watch the video and are given a written transcript of the video to use as reference during the discussion of the student thinking they noticed in the video. The use of a transcript largely focuses teachers' attention to student thinking that is expressed verbally. While this has been productive, the work on student learning makes explicit the role of gesture, action, and other multimodal thinking (e.g. Hall & Nemirovsky, 2012). For instance, gesture can be used not only to communicate student thinking but to help children make sense of ideas (Roth & Thom, 2009). Attending to multimodal student thinking opens up learning opportunities for students in one-on-one tutoring situations (e.g., Flood et al., 2015) and in classrooms (e.g., Shein, 2012). For this reason alone, we should include multimodal thinking when discussing teacher noticing, though it has not been the primary focus thus far. In addition, recent work on multimodal teacher noticing (MMTN) (Walkoe, Williams-Pierce, Flood, & Walton, in progress) has found that when teachers attend to students' gesture in mathematics PD, they also shift the types of questions they pose from a focus on math facts to more open-ended, resources-based questions.

In this talk we will demonstrate how student gesture and action can be deeper windows into their thinking in the classroom. We will present a short video clip to demonstrate student geometric and algebraic thinking that is visible primarily through gesture and action.

We will then provide an example of a video club that was designed to utilize a video annotation tool (www.anotemos.com) to support teachers' noticing of multimodal student thinking. This was the first time the teachers participated in a video club and we found that their discussions about student thinking were productive and consistent with what we have seen in more advanced video club work. In particular, the teachers took time discussing specific instances of student thinking, as opposed to jumping around from idea to idea. Additionally, they delved deeply into the student thinking they noticed and the discussions were substantial. In prior video club work, we have not seen these rich ways of discussing student thinking until further into the video club sessions (e.g., Walkoe, 2015). The video tagging format also seemed to support teachers in noticing a range of student thinking, including thinking expressed through gesture.

Finally, we will discuss work in progress, that continues to investigate the effectiveness of video clubs designed to support MMTN and the connection between a multimodal focus on teacher noticing and the richness of teacher noticing and video club discussion.

Social positioning in collective embodied models in an elementary STEM classroom

Nitasha Mathayas, Joshua Danish, Xintian Tu, Mengxi Zhou, and Morgan Vickery

In this paper, we examine the collective embodied activity of students in an elementary science classroom to explore how their dynamic movement within the classroom shifts their social positions as knowledge creators. A core focus of our research is on collective embodied learning: how students' collaborative embodiment of scientific concepts acts as a physical and conceptual tool that mediates their collective efforts to construct understanding about the phenomena they are modeling (Danish et al., 2020). Our research is framed within Cultural Historical Activity Theory as we see classroom learning as inherently sociocultural and imbued with cultural and historical meanings that influence how teachers and students learn in interaction (Engeström, 2018). A key element of this is *social positioning*, which describes how joint interaction dynamically positions participants in different roles during activity, and highlights how these roles are imbued with differing levels of power to make epistemic decisions, even when participants are not consciously aware of them (Davies & Harré, 1990; Miller et al., 2018). In this paper, we explore how first and second-grade learners' knowledge building activities in a mixed reality environment were shaped by their constantly shifting physical and social positioning as they explored states of matter at the particulate level.

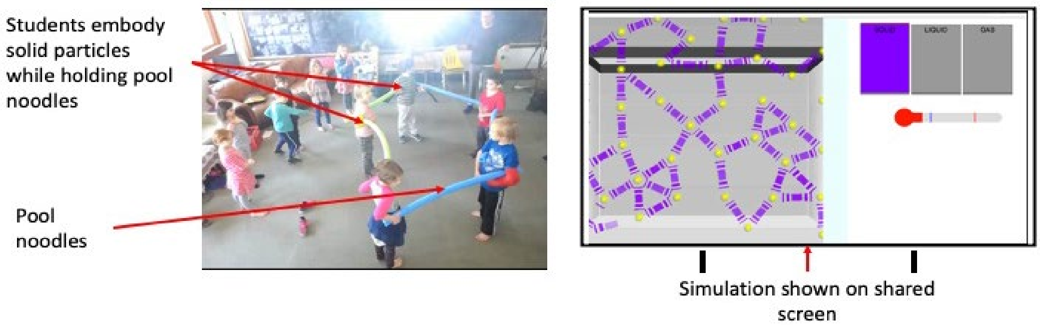

Figure 1. Students-as-particles embody a solid (ice) while holding pool noodles to represent bonds between them. The instructors and other students observe the group and the simulation.

Our current analysis focuses on a seven-day unit about energy and states of matter using a mixed reality simulation called Science through Technology Enhanced Play (STEP; Danish et al., 2020) that was implemented in a mixed first and second grade classroom in a private school in an urban Midwestern city (Tu et al., 2020). STEP lets students explore the relationship between particle behavior and states of matter by collectively enacting how they think particles respond to different amounts of energy and simultaneously observing their movement as molecules in the simulation (see Figure 1). In the unit, students explored different characteristics of molecular movement and intermolecular bonds by acting as molecules and using props such as foam pool noodles to support their collective enactment. Using methods of interaction analysis (Jordan & Henderson, 1995), we analyzed video recordings of the classroom interaction and the simulation across the unit and focused on how students' social and physical positions changed and influenced each other.

Our analysis shows how movements within the collective model simultaneously impact and are shaped by the current social positioning that those very same movements appear to help construct. For example, the instructors shifted at times from taking a "typical" directive teacher role standing outside the model offering suggestions, to actively participating as a particle in the space. When they were in the external teacher role, students tended to listen attentively to them. However, as soon as students began moving, the teachers' role as "external" to the model was reified as the learners oriented toward each other and the projected simulation, limiting the impact of the teacher on their collective modeling until they paused. This led the students to explore their own ideas about particle behavior in-the-moment, and the teacher was limited to helping them reflect on those realizations after-the-fact. Similarly, when one teacher joined in the model as a particle, they began by offering suggestions about the model that led the students to move in response, however, as the students began moving, the teacher also reacted to their motions, creating a more equal footing as the group acted in coordination, and began to recognize underlying patterns in particle movement.

Taken together, these different forms of interaction show how it is impossible to separate the social role of movement within embodied modeling practice from the knowledge building role of that same movement. The continuous movement of participants has cascading effects on their collective embodiment and social positioning. Thus, it is important for educators and designers who aim to leverage whole-body embodied learning to think about the unique way that physical positioning contributes to social positioning that in turn promotes or constrains embodied agency within these contexts.

Revisiting positioning: How a teachers' physical movements amplify socio-epistemic messages in the classroom

Susan Kelly and Christina Krist

This paper uses both physical and epistemic positioning to track how a teacher's talk and physical movement support students in knowledge building. Students come to understand expectations relative to knowledge building and their role in the process through the interactional routines that occur in the classroom. They pick up how they are expected to respond based on how a teacher frames the environment and the kind of ideas the teacher gives space to in the classroom (e.g., Scherr & Hammer, 2009; Russ & Luna, 2013). A teacher conveys these ideas through the *epistemic messages* they send that emphasize what kind of knowledge counts and how students are expected to participate (Russ, 2018). Because these messages are continuously communicated through teacher and student interactions and are dynamically negotiated moment-to-moment, they work as *socio-epistemic messages* that guide how students interact with each other and with the ideas they are constructing in their work together (Kelly, 2020). In this paper, we explore how Mr. M, an experienced teacher who enacted reform-aligned science instruction, used his physical positioning to amplify and emphasize the discursive socio-epistemic messages he communicated during an eighth-grade science class.

Focusing on one socio-epistemic message, we describe how Mr. M uses his physical movements to amplify the message *Everyone's Ideas are Valued* he communicated (Kelly, 2020). This message conveyed to students that their ideas were important and that their contributions were taken seriously. To do this, Mr. M often used metadiscursive affirmations like "Great idea" or "That's cool" in response to their ideas. He also encouraged students to go public with their ideas by asking students to speak loudly so their ideas would be heard by the classroom community. He also emphasized making ideas public by revoicing their thoughts or by asking students to revoice their peers' ideas.

This video case was drawn from a larger project that investigated middle school students' participation in science knowledge building practices. In our analysis, we examined 15 video recordings of lessons taken from the beginning, middle, and end of a multi-day Earth science unit that investigated the movement of the Earth's plates. The students, who were ethnically and economically diverse, were initially reticent to engage collectively in the intellectual work at the start of the unit, so Mr. M was actively working to develop a classroom community that would encourage their participation as agents in their own learning.

Using a grounded approach, we conducted video analysis to characterize how Mr. M positioned students to do the knowledge building work by tracking his talk and physical movement. To do this, we completed a line-by-line analysis of whole group discussion to identify the epistemic messages Mr. M conveyed (see Kelly, 2020 for additional detail). Concurrent with this analysis, we created a multimodal transcript describing Mr. M's physical movements during each class. Within this transcript, we identified moments with an obvious or dramatic shift in physical position. We then compared whether particular physical movements coincided with the coded epistemic messages and documented these patterns and relationships in analytic memos.\We identified three distinct patterns of physical movement that Mr. M used in conjunction with the message *Everyone's Ideas are Valued.* Each of these movements served to amplify the message, albeit in different ways. We provide a brief example of each. First, one pattern of physical positioning involved Mr. M *moving away from the speaker* while verbally positioning them with intellectual authority. For example, during a discussion in which students were sharing initial ideas, Mr. M acknowledged a student, Vanessa's, idea was interesting and then moved to the opposite side of the room while asking her to repeat her idea in a louder voice. A second pattern involved Mr. M *moving toward the speaker* to emphasize their ideas. In this case, Mr. M moved toward speaker while simultaneously revoicing that speaker's idea to emphasize or clarify it. For example, after Jason shared his idea about how tectonic plates converged, Mr. M moved toward Jason to make sure he was imitating Jason's hand gesture for convection correctly and if he was revoicing his idea accurately. Finally, while Mr. M rarely stood at the front of the room during class activities and instead moved around the room, he would often *move to the side of the speaker(s*), effectively positioning students to take on the intellectual work by physically and discursively giving them the floor. Sometimes Mr. M would sit at or on a table with the rest of the class while students drew and discussed their ideas at the board. In these instances, he physically positioned himself to as member of the community, rather than an authority.

Taken together, Mr. M's physical positioning, moving *away from*, *toward*, or *to the side* of the student(s) speaking served to amplify the socio-epistemic message, *Everyone's Ideas are Valued,* he was communicating discursively. He encouraged students to "go public" with their ideas and act with agency. He reinforced this notion by using physical movements to increase the "airtime" for student's ideas, so their ideas could be examined, critiqued, and modified by the classroom in their knowledge building endeavors. Showing how discursive and physical positioning work together to laminate the socio-epistemic messages conveyed in the classroom is an important consideration for educators who are, knowingly or unknowingly, continuously sending messages about learning to their students.

Making space for joint exploration: The embodiment of social and epistemic positioning in student-teacher interaction

Erika David Parr, Nessrine Machaka, Elizabeth B. Dyer, and Christina Krist

Across reform efforts in mathematics education is an emphasis on involving students productively in the intellectual work of the discipline. Often, this involves re-negotiating the roles and authority structures typical in school contexts in order to position students and teachers as partners who are jointly exploring disciplinary questions (Scardamalia, 2002). This re-negotiation is both social and epistemic: it is a marked shift from classroom structures in which a teacher holds the majority of intellectual and social authority.

In order to better understand how joint exploration of ideas between students and teachers as partners is established and maintained through interaction (Keifert & Stevens, 2019), we analyzed an episode in a secondary mathematics classroom in which a teacher responded to a student's wondering. We adopt the theoretical framing of positioning (Davies & Harré, 1990) to consider social and epistemic authority, while also foregrounding physical positioning in our analysis. The focal episode comes from a dataset of classroom video of teachers who were developing responsive teaching practices in secondary mathematics. We view responsive teaching practices as pedagogical tools that build on students' ideas, wonderings, and sensemaking; accordingly, the use of such practices requires that teachers establish and maintain moments of joint exploration with students. We selected one teacher, Rachel, as prior analyses demonstrated that she consistently used responsive teaching practices (Dyer & Sherin, 2016). Using "joint exploration" as a sensitizing concept (Blumer, 1954), the research team reviewed Rachel's videos from 10 100-minute class periods to identify potential episodes for close microanalysis.

Figure 2. Four physical positions of the teacher (from left): Position 1- standing upright, Position 2- leaning back, Position 3- standing, leaning over table and Position 4-standing leaning over table with head down

In this paper, we present our microanalysis of one identified episode of "joint exploration" in order to begin to elucidate social, epistemic, and physical patterns around how such explorations are established and maintained. In this episode, Rachel, interacts with two students who are seated next to each other, James and Steven. We analyzed Rachel's physical positions throughout the episode and found that Rachel assumed one of four positions, shown in Figure 2. To analyze social positioning, we considered a person to assume social authority when giving a social directive that was followed by others in the group. Similarly, we analyzed epistemic (intellectual) authority by considering whose mathematical ideas were proposed and taken up by the group.

From this analysis, we identified a strong relationship among physical, social, and epistemic positioning in establishing and maintaining joint exploration of a mathematical idea. Of the 10 shifts in Rachel's physical position in the interaction, 9 were associated with a shift in her social and/or epistemic authority. Conversely, no shifts in Rachel's social or epistemic authority were observed without a shift in physical position. Further, we found that shifting between certain positions often coincided with certain epistemic or social moves.

To illustrate this phenomenon, we focus on one shift in physical positioning (from position 1 to 2; see Figure 2) and describe the change in epistemic positioning that served to ***establish*** joint exploration. We argue that this shift involved a concurrent release of epistemic authority by Rachel and an uptake of epistemic authority by James and Steven. As James asked the teacher a question about whether there is "a natural log that is equivalent to e" while "messing around with [his] calculator" and looking up at her, Rachel restated James' question, paused, stepped back, and shifted from physical position 1 to position 2. The question appeared to catch Rachel off guard, as she did not provide an immediate response. Rachel then remained in position 2, leaning back, as she tried to understand James's question by asking clarifying questions. Steven then intervened to affirm Justin with "I mean yeah, cuz it'd be a power" to which Justin replied "of e, right?" leading to a discussion between Steven and James with little feedback from Rachel. Notably, Steven and James arrive at a solution to James' question that they were both satisfied with, without any affirmation from Rachel.

During this episode, Rachel's shift backward created space, both physically and metaphorically, for James and Steven to take up the intellectual authority within the conversation. Through our analysis of an episode that contained joint exploration, we found that shifts in the teacher's physical positioning were highly correlated with shifts in social or epistemic positioning within the group. Furthermore, patterns have begun to emerge among certain positions and their associated shifts in authority and interactional dynamics. We illustrated one such shift here, demonstrating how a particular shift in the teacher's physical positioning, coupled with verbal and other interactional dynamics, served to create space for students to take up intellectual authority. These findings suggest that shifts in a teacher's physical positioning may be a strong indication of changes in social or epistemic positioning and/or are an important part of conveying social and epistemic messages. We offer the suggestion of triangulating physical, social, and epistemic positioning to develop in-depth analysis of how authority is negotiated to establish and maintain moments of joint exploration in mathematics classrooms.

Ananda Marin, University of California, Los Angeles, amarin1@ucla.edu

Abstract: In this symposium we work toward our responsibility in learning how to be human through a deep reciprocal relationship to and with the more than human, by interrogating an influential method in the learning sciences, interaction analysis. As settler scholars learning to "set aside the ways of the colonist" (Kimmerer, 2013, p. 207) we aim to think with Indigenous Ways of Knowing (IWOK) to reinterpret the methodological commitments of interaction analysis. In acknowledgment of the continual learning required for this goal, we propose a symposium where authors and audience members learn together, engaging in two iterations of a video analysis session around the same piece of data: one using more traditional interaction analysis methods, and one engaging with our emerging understandings of a relational ontology. Our two discussants, leading scholars of both IWOK and interaction analysis in the learning sciences will support analysis sessions and subsequent discussion.

> "*Indigenous* is a birth-right word. No amount of time or caring changes history or substitutes for soul-deep fusion with the land. Following Nanabozho's footsteps doesn't guarantee transformation of Second Man to First. But if people do not feel 'Indigenous', can they nevertheless enter into the deep reciprocity that renews the world? Is this something that can be learned?" (Kimmerer, 2013, p. 213)

In this symposium, we propose to work toward desettling and expanding a commonly used (and settled) method in the Learning Sciences, interaction analysis (Jordan & Henderson, 1995), by thinking with Indigenous Ways of Knowing (IWOK; Bang & Marin, 2015). Rather than adopting and decontextualizing IWOK to fit into what the method already is (Afonso Nhalevilo, 2013), we take what we see as a settler responsibility to interrogate how conventional interaction analysis is rooted in settler colonial logics and surface what needs to be reimagined. As scholars who do interaction analysis, we believe that starts by interrogating the settler-colonial logics of research, and truthmaking, that undergird the rooted ontologies from which it has sprung. In acknowledgement of the complex and necessarily ongoing nature of desettling work, this symposium is structured as an alternative to the traditional symposium structure of a collection of paper presentations. Instead, we invite members of the learning sciences community to participate in a data session with us to first interrogate the settled assumptions embedded in interaction analysis methodology, and then to explore alternative ways to take up interaction analysis commitments that at the same time position us to be in ethical relation with our human and More Than Human (MTH) research partners. To this end, we will, with gratitude, be joined by two scholars, Megan Bang and Ananda Marin, who have transformed our own and the learning sciences' understandings of IWOK and the possibilities of interaction analysis to incorporate a relational ontology. They will serve as "discussants" in the data session symposium, participating in data analysis with the group, stewarding our efforts to take up IWOK in interaction analysis, and providing discussion points along the way.

Learning from Indigenous Ways of Knowing

In her book Braiding Sweetgrass, Robin Kimmerer shares the story of Nanabozho - part man, part manido, immigrant on Turtle Island (known to colonizers/settlers as North America) populated with worlds of animals, plants, winds and waters. When placed here by the creators, Nanabozho was assigned the responsibility of learning how to be human from the many MTH beings that already inhabited the world. Their advice to not "control or change the world as a human, but to learn from the world how to be human" (Kimmerer, 2013, p. 208) formed the beginnings of the original instructions passed down through generations of Indigenous peoples on Turtle Islands - the First Man. Since the time (2) of Nanabozho, the many waves of colonizers, settlers and immigrants - the Second Men - brought with them an approach to being human informed by an ontology that views humans as separate from and higher in a material hierarchy than the MTH. Unlike Nanabozho who was made responsible for learning *from* and *in relationship with* the MTH, 'Western' or 'Eurocentric' ontologies lay claims to objective truths informed by Francis Bacon's call to "bind nature and reduce her to a slave" (Semali, 2002, p. 30). Rooted in living in and with the MTH, IWOK prioritize a relational ontology and value taking care of the land through an understanding of the nuanced relationships between and within humans and the MTH from a holistic framework. This way, neither humans nor the MTH are higher in a material hierarchy since the MTH world is deeply embedded in how reality emerges. In stark contrast to this, settlers have had little interest in the responsibility embedded in living with the land. Over the last few centuries, they have enacted oppressive extractionist frameworks through residential schooling systems, claiming and stealing land by displacing Indigenous peoples from their homes and the ongoing pollution of unceded Indigenous territories to mine and extract nutrients from the Earth (amongst many other acts of violence). In this symposium, we seek to shift away from this colonial ontology by learning from IWOK to decolonize our ways of understanding reality. In discussing the role of colonizers who want to decolonize their ways of being on Turtle Island, Kimmerer asks what it might mean for us to live on this land "as if we were staying [...] with both feet on the shore" (Kimmerer, 2013, p. 207). Her question pushes non-Indigenous people to consider how we might learn to be human as though our "ancestors lie in this ground [...] to take care of the land as if our lives and the lives of all our relatives depend on it. Because they do" (Kimmerer, 2013, p. 215). Embedded in Kimmerer's question is a call for the Second Man to consider our responsibility in learning how to be human through a deep reciprocal relationship to and with the MTH. In this symposium, we take up this call to "set aside the ways of the colonist" (Kimmerer, 2013, p. 207) by deeply engaging with a relational ontology towards decolonizing how we understand learning.

In this work, we understand Indigenous knowledge systems as "a product of the cognition of the people that predate westerners and have operated independently of the western paradigm for thousands of years" (Hewson, 2015b, p. 41). While disparate in their particulars, IWOK across the world do share commonalities in their worldviews such that reality comes into being in, with, and through nature and human beings (Smith, 1999) be it Indian tribal communities' use of plants for medicine (Ignacimuthu, Ayyanar, & Sivaraman, 2006), the science of *titen* developed by the Java community in present day Indonesia (Wilujeng & Prasetyo, 2018), or the Indigenous knowledge for artisan fishing in Mozambique (Afonso Nhalevilo, 2013). Framed as 'relational epistemologies' (Bang, Marin & Medin, 2018), IWOK center relationality, emphasizing the responsibility required in human-MTH relationships so that we not only "honor the knowledge in the land" but also engage in "caring for its keepers" (Kimmerer, 2013, p. 210). We draw on Bang, Marin & Medin (2018) to inform how we frame relational epistemologies by recognizing that we need to:

1. view humans as a part of the natural world, rather than apart from it;
2. attend to and value the interdependencies that compose the natural world;
3. attend to the roles actors play in expanded notions of ecosystems from assumptions of contribution and purpose, rather than assumptions of competition;
4. focus on whole organisms and systems at the macroscopic level of human perception (also a signature of complex-systems theory);
5. see all life forms as agentic, having personhood and communicative capacity (as distinct from anthropocentrism);
6. adopt multiple perspectives, including interspecies perspectives, in thought and action; and
7. weigh the impacts and responsibilities of knowledge toward action." (p. 151)

Learning from Indigenous scholars in the field, we seek to engage in recognizing <u>relations</u> as our unit of analysis. This speaks not only to our attempts at learning from (rather than about; Jones and Jenkins, 2008) IWOK but also to the ethical dimensions of what we analyze (who, and for whom/towards what ends) (Philip, Bang & Jackson, 2018). We recognize this work as part of our learning *how* to be relation in and with this land and engaging with the need for our "commitment to transform processes that uphold and assert Western epistemic supremacy" (Bang, Marin, & Medin, 2018, p. 156).

Within the Learning Sciences, we look to Indigenous scholars (and their collaborators) who have shared decolonial understandings of human-MTH relations towards more expansive conceptions of learning both in and out of formalized education settings. Building on much of Gregory Cajete (e.g., 1994 and 2000) and Douglas Medin's (e.g., 2006) work in illustrating different cultural conceptions of human-nature relations (Medin, 2006) that highlight Indigenous knowledge systems as rooted in a relational ontology (Cajete, 2000), Megan Bang and Ananda Marin have brought to the fore *how* we can understand learning from a decolonial perspective. "Settled expectations" (p. 303) in schooled science education impose colonial human-nature divides, restricting both the "content and form" of knowledge systems valued within education spaces that then "devalue(s) and dismiss(es) boundary-expanding forms of knowledge, experience and meaning-making" (Bang, Warren, Rosebery & Medin, 2012, p. 303). In addition, focusing on formalized school spaces as the primary sites for learning further marginalizes Indigenous youth by positioning them in "untenable epistemological positions that work against engagement in meaningful learning" (p. 303). Formalized schools on Turtle Island were built through colonial frameworks to dominate and eradicate Indigenous communities and IWOK, and continue to marginalize Indigenous youth through purporting a colonial ontology. Looking to non-formalized learning spaces, Bang, Marin and other colleagues show how we might understand a decolonial approach to learning that values MTH entities as part of knowledge creation (Bang, 2012, 2020). For example, Bang & Marin (2015), Pugh, McGinty & Bang (2019), and Marin (2019) explain how walking, reading and storying the land as methodology provides a space for intergenerational interactions and relationship building with the MTH that liberates youth towards engaging in decolonial scientific practices. This approach to analyzing 'learning on the move' (Bang, 2020) is rooted in Interaction Analysis methods that focus on "assemblages of micro-practices" (Marin, 2018, p. 96) and 'ambulatory sequences' as the unit of analysis to desettle our focus from shifting speakers, towards "configurations of movement" (p. 96) that prioritize human-MTH relations.

Authors' positionality

To "live with both feet on shore" (Kimmerer, 2013, p. 210), for each author, requires that we not only deeply engage with and learn from Indigenous scholars such as Gregory Cajete, Megan Bang and Ananda Marin amongst others, but that we also recognize and are accountable to the many relations that brought us to this shore. While all three authors identify as non-Indigenous, each one of us brings relations with ancestors connected with and through different lands and communities of MTH beings. Doing the work of honoring the knowledge in the land does not begin and end with decolonizing our approach to research but is *one* way for us to continue to learn how to live with responsibility in relation with the human and MTH worlds.

I (Rishi) am a settler on Turtle Island, living on the traditional territory of the Mississaugas of the Credit, the Anishnabeg, the Chippewa, the Haudenosaunee and the Wendat peoples. Part of the South Asian diaspora, I am connected with South Indian and queer ancestry. In my (biological) family spaces, understandings of learning were rooted in pre-colonial (South Indian) relational ontologies, and I was formally educated through Krishnamurti and Steiner schools that prioritized learning in and with the MTH. However, my parents were also deeply embedded in and committed to reproducing Brahmin supremacy (i.e., why they prioritized private, 'alternative' schools). Thereafter, much of my formalized learning engaged with colonial disciplined science. It was through my relationships with the marshy wetlands and the queer, trans, Black, Indigenous and people of colour communities in Tkaronto that I began to desettle my own commitment to colonial ways of knowing.

I (Colin) am a settler on the lands of the Lenape. I carry with my Elliott name paternal ancestors who were early perpetrators and beneficiaries of settler colonial violence, some having reached the shores of the US as early as the 18th century. My Hennessy name tells a familiar European immigrant story, with little known about how my ancestors two generations before me fled a famine-ravished Ireland to the United States. My relationship to knowing comes from my family, raised by queer moms who continually challenged me to see privilege and showed me what struggling for collective change can look like and my father who knows the value of a good story. As a physics teacher I was confronted by how the colonial science – which I was so steeped in from my own formal schooling – is an ontological source of injustice and violence. I continue to learn from scholars, and youth, who challenge me to do to work to recognize my own colonized perspectives and imagine differently.

Beneficiaries of the Hart-Celler Act of 1965, my (Jasmine's) parents immigrated from Taiwan to the US, both seeking advanced graduate degrees in technical fields. I was subsequently educated almost exclusively in White-dominated private school settings, with the understanding that this kind of (settler) education was the key to liberation from poverty. My graduate preparation was steeped in the traditional learning sciences discourses of cognitive science and ethnomethodology, but also oriented me to being open to interdisciplinary (and therefore epistemological) surprise and wonder, and to operate in the service of positive change for the collective.

Interaction analysis in the learning sciences

Given our commitment in the learning sciences to study and design for learning in situ (Hoadley, 2018), interaction analysis has been taken up by many in the field – including the authors and discussants of this symposium – as a useful tool that situates cognition in social life and privileges participants' perspectives and meaning making in the course of dynamically unfolding activity (Jordan & Henderson, 1995). This has proven invaluable for understanding the breadth of human practice and what can and should count as knowledge and learning, beyond narrowly defined notions of, for example, "mathematics" (Hall & Stevens, 2016). Additionally, it has proven powerful for bridging between structural and individual explanations for human behavior and cognition (Erickson, 2004), providing analysts with tools to look across social and developmental scales. However, while even early uses of the method in the learning sciences incorporated ethnographic analysis (Jordan & Henderson, 1995), interaction analysis has roots in ethnomethodology and conversation analysis, where a deep commitment to analysis held accountable to data of naturally occurring talk and interaction as primary. Therefore, inferences not grounded in empirical evidence in audio or video records are not permissible. To an extent, this has constrained scholarship that uses this method from engaging with broader sociohistorical and sociopolitical issues relevant to learning. In other words, while interaction analysis has been used to illuminate and describe foundational phenomena in the learning sciences--professional vision (Goodwin, 1994) and disciplined perception (Stevens & Hall, 1998), what counts as a context (McDermott, Gospodinoff & Aron, 1978), and talk moves like initiation-response-evaluation sequences (Mehan, 1978) and revoicing (O'Connor & Michaels, 1993) – it is rare that it is deployed to grapple explicitly with issues of power or broader cultural contexts that are not explicitly referenced, or "demonstrably relevant" in the data (Garfinkel, 1967). This is not to say it cannot be done. Gutiérrez, Rymes, and Larson (1995) demonstrated how attending to the joint accomplishment of social order and sense making in dynamically unfolding activity allows researchers to bring together the role of human action and interaction with how social structures may operate – but be variably taken up, resisted, or remixed. Their analysis revealed how official and unofficial scripts may come into contact in classroom spaces, producing the possibility of a third space where transformation and disruption of sedimented power structures may occur. This kind of work is rare but inspiring for the future of interaction analysis.

As the field of learning sciences continues to develop, scholars are taking up interaction analysis in increasingly expansive, yet still rigorous ways. These expansive methodological developments are not just in line with the increasing ease of recording and capturing data that cheaper and smaller digital technological tools have brought, but in fact challenge fundamental assumptions about what learning is and how to analyze learning activity from video data. For example, recent scholarship on "learning on the move" (Marin, 2020; Bang, 2020) has introduced theoretical arguments and methodological tools for looking beyond sedentary, classroom-like settings for where and how learning happens. Vossoughi and colleagues (2020), as another example, relied on interaction analysis to trace in-the-moment phenomena and longer scale trajectories of participation as a way to make the history of unfolding relationships part of what is available in the data.

Introducing the data for analysis

In the tradition of Koschmann's (2011) edited volume - the outcome of a group of learning scientists gathering to analyze the same set of video data with different theoretical lenses - we seek to interrogate our methodological (and therefore theoretical) commitments, and the consequences they entail. Our data were generated as part of a four-year ethnographic study of a youth robotics team, Turing Robotics, that relied on video recording methods and microethnographic analysis (Erickson, 2004). The vast majority of the data were recorded in the teams' basement shop at Turing High School (THS), where members of the team spent, on average, over 15 hours a week each competitive season (January through April) working with machines and materials to design a robot, build the robot, program the robot, operate the robot, strategize for competitions, and organize as a team. Almost all the youth who participate on the team are students at THS and identify as Black and/or Latinx in some way. The large machines that populate their workspace, particularly one evident in the selected episode, are vestiges of the past when the basement space was once part of a vocational school in the 1980s, and not the engineering focused high school that THS was at the time of the study.

I (Colin) partnered with the team to explore how youth learned as they participated. Over the multiple seasons, I began to take on more of a mentor role, in addition to being a researcher. I chose what to record as team action unfolded in an emergent way (Goldman-Segall, 2002); I selected particular important moments to explore further because they stood out in reviewing the corpus (Erickson, 2004; Jordan & Henderson, 1995); and I transcribed the data in multiple ways recognizing it as an act of theory itself (Ochs, 1979). Each of these actions shaped the data as it is presented in the selected episode. The particular clip we selected for this symposium shares two different angles on unfolding action as multiple youth engage with a large machine that bores holes and cuts metal parts as designed. We see this symposium as a space to not only recognize the settler logic that encompasses the larger research project, but to learn how an IWOK framework might decolonize analysis of such video-data based research. Working backwards from data generated we aim to collectively explore how we might desettle the methods (and in turn methodological assumptions) towards reimagining our understandings of learning.

Mill relationships

The focal episode was generated in the fourth year of the research project as youth worked with a central machine in their shop called a CNC three-axis mill press, or just "the mill". In this particular instance, the machine and youth collaborated on lining up and boring a hole in a metal part that would later be used to bolt it onto the robot and act as a part of the robot's "arm" (see Figure 1). The unfolding action of these 90 seconds were selected because they depicted the ongoing relationships between the mill and youth as they worked towards making the robot. The actions depicted are ripe for a traditional interaction analysis because it shares various embodied motions, speech, and human-machine interactions. Finally, the episode also shares some of the typical practices that youth engage in as they learn to participate in particular team tasks including; observing a more expert perform, and step in to engage with some parts of the task. Table 1 describes the actors that emerge in the episode.

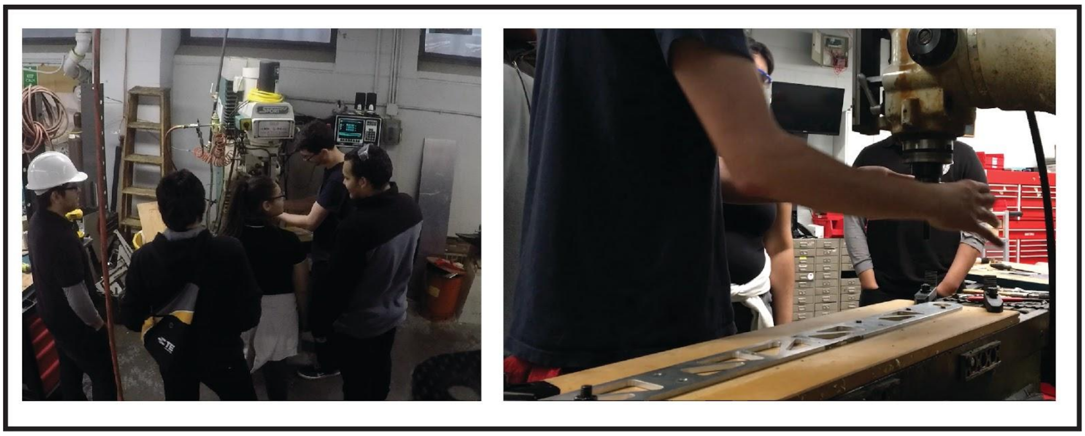

Figure 1. Two different perspectives of the actors in focal episode as they change the end bit on the mill

Table 1: Actor descriptions

Actors	Description and Notes
CNC three-axis Mill Press	Originally installed when the school was a vocational school as part of a classroom of large machines in the 1980s. Uses floppy disks for data transfer. Now the only one of its kind in the teams' shop. Called "the mill."
Metal robot part	This flat aluminum piece on the mill's table was possibly part of a previous robot (indicated by the various triangles that have been cut out of it "to save weight" without compromising structural integrity). This part will eventually become a stable part of the robot's arm that is attached to the base of the robot and to the other, moving, part of the arm.
Leia	A first-year newcomer to the team who identifies as a young woman of Cuban descent. She is particularly interested in working on the machines and learning to design robot parts. This episode is early on in her relationship with the mill, which she later becomes one of the experts at the mill, working with Santiago in future seasons.
Jav	The 4th year captain of the team who identifies as a young man of Portuguese and Brazilian descent. He began his relationship working with the mill three years before. He is now considered by the team the expert at using the mill. He recognizes that he is about to graduate and needs to help younger students learn how to operate with the mill so they can continue the tradition of cutting parts with it in future seasons. After graduating high school, he took on a job as a machinist at a local company.
Santiago	A first-year newcomer to the team who identifies as a young man of Dominican descent. He immediately began following Jav around when he started participating on the team, hoping to be his apprentice. His relationship with the mill is emerging through Jav's ongoing work at it. He later becomes an expert at the mill, working with Leia in future seasons.
Nick	A fourth-year member of the team who identifies as a young man. He consistently floats between various tasks on the team, often supporting new members in learning how to do various tasks. He has not developed a relationship with the mill much at all besides observing work, as he does in this episode. He later goes to the local college studying to be an engineer.

Jav, Leia, Santiago (and a few other onlookers) moved around and with the mill as the group prepared to bore a hole in the metal piece that sat on the table (see Figure 1 for two different angles generated at the same point in time). Over the course of the episode, depicted in Figure 2, Jav brought a new bit to the Mill, Leia stepped in to tighten it with a specialty wrench, Santiago came back to hold the mill's break so the end did not spin as Leia tightened, Leia tightened the chuck around the bit and stepped away, and Jav stepped in while flipping the switch to make the bit spin.

Jav: ((places bit into the end of the mill)) Ok, now
Sanitago: Now you -- now you do it one handed.
Jav: ((spinning chuck around bit to hold in place)) can't reach
Nick: Technically you did it with two hands.
Santiago: ((chases Nick away; laughs))

Jav: Tighten that back up
Leia: ((grabs the wrench and leans in to the chuck))
Leia: ((spins the chuch with the wrench))
Jav: If you're moving the chuck it's not gonna do nothin. One of yous gotta hit the break.

Leia: ((points towards the break))
Santiago: ((grabs the break lever))
Nick: Push it forward (12s)
Santiago: Ut uhh fat boy strennngth.
Leia: ((pushes then stops, removes wrench, and steps back))
Santiago: That was pathetic. ((Leia places wrench and keeps pushing again)) You have no um type of strength whatsoever.

Jav: Lean into it. You gotta put your body in it.
Leia: ((wrench starts to move))
Santiago: THERE we GO:::
Jav: The only way I can do it. (1s) That's good enough. Alright let me try it ((flips switch on mill; it spins))
Leia: You heard what I said. ((pokes Santiago's stomach with wrench)) you lose some fat.

Santiago: Yeah I did. THE MORE BLOOD I LOOSE THE MORE WEIGHT I LOSE.
Leia: That's not how it works.
Santiago: I know.
Leia: ((looks to onlooking student as she places down the wrench on the mill)) Not good enough.

Figure 2. The mill actors' episode (90s); underlined represents the frame pictured

Organization of the data session

We propose collectively analyzing the data shared above in two different ways to surface the tensions between interaction analysis rooted in a colonial ontology, and analysis emergent through a relational ontology rooted in IWOK. The symposium will begin with the authors and discussants situating the symposium aims within the responsibilities of settlers/colonizers in learning from IWOK. The remainder of the symposium time will be split into three sections. The first and second for interaction analysis, then relational ontology microanalysis of the data, and the third for summarizing discussions around disrupting our settled, human centered ways of seeing. We conclude by sharing our protocol and guiding questions for the two rounds of data analysis. In both versions of the data analysis, we will follow a protocol adapted from that described by Jordan and Henderson (1995):

1) Watch the whole 90s clip without stopping.
2) Watch the whole 90s clip with the 'stop protocol'. This protocol encourages audience members to ask the authors to stop the video anytime someone asks, so that we may collectively discuss what they see/notice.
3) Audience members will be invited to share what they would like to trace/notice in the next viewing, to ensure we encourage different perspectives on what to follow.
