4) Watch the 90s clip again with stop protocol. We will encourage audience members to include or add to the traces shared before.

5) Round of reflection and wondering, where we will ask audience members to comment on:
   (a) What can you say is happening here?
   (b) What do you wonder about?
   (c) What role might other data (ethnographic, or different video data) help with?

Additionally, we will use the following norms and assumptions (many borrowed from comments by Ananda Marin and Shirin Vossoughi at a workshop at Northwestern University in 2019 convened by Marcelo Worsley):

- We treat the data as a gift, and remember the real people who are sharing with us
- Participants are sensible, capable, and act with intelligence and ingenuity
- Conditions for interaction are always being shaped, and interaction forms its own context
- We are looking at the details of moment-to-moment coordination of joint action
- We ground our noticings in what is available in the data

We propose performing the data viewing sessions with the guidance provided in Table 2, each contending with the protocol from above (1-5) and the norms and assumptions shared above.

Table 2: Two different Data Viewing guidelines

First Data Viewing	Second Data Viewing
Collective analysis of the video clip through traditional interaction analysis methods that center human participants in the unfolding interaction will use these guiding questions:	The authors and the audience, learning from and with the discussants, will engage in group analysis of the same video data, recognizing relations as the unit of analysis guided by the following questions:
● To what are human actors orienting across the material landscape? ● What sense are human actors making of their worlds? ● What resources support joint activity? ● How do previous actions provide contexts for subsequent action?	● What kinds of human-MTH relations emerge in the data? ● How does the metal piece contribute to the ongoing unfolding interaction? ● How does the mill-human relation form part of a local ecosystem? ● Where does the mill end and the human actor begin?

Endnotes

(1) The two first authors contributed equally to this work.
(2) In the telling of this story, Kimmerer explains that Indigenous recognize circular (and not linear) time. Therefore the time of Nanabozho is both a past and a telling of the future that is to come.

Abstract: Human-Centered Design (HCD) is a growing field that has the potential to positively impact students' learning. A general consensus on the terms, practices, scaffolds, and assessments of HCD can foster its effective implementation in K-12 and post-secondary education. This session brings together researchers whose work is focused on implementing HCD across K-16 classrooms. It aims to develop a coherent definition of HCD, its methods, practices, and assessments, to help frame the field and reduce ambiguity at a critical time in its broader adoption.

Introduction

Engaging students in problem solving experiences during project or problem-based learning has long been shown as a particularly effective means for students to learn both content and thinking strategies (e.g. Hmelo-Silver, 2004). While effective, many of the problems that students are tasked with in these curricula do not have a direct connection to their lives and experiences outside of the classroom. This disconnect between the content and their lived lives has been shown to cause students, particularly those underrepresented in STEM, to self-deselect from many career pathways, because they cannot envision how what they learn will have an impact on them and those they care about (Valla & Williams, 2012). In response, Human-Centered Design (HCD) is an approach that focuses problem-solving on the real needs of real people (Brown, 2008). In many ways, HCD has been shown to help students develop human-centered, experimental, collaborative, metacognitive, communicative, and creative mindsets (Goldman et al., 2012; Razzouk & Shute, 2012). With these mindsets, students become better prepared to effectively engage in future learning endeavors and actively participate in today's globally competitive world.

While, there has been increasing research into how we can best engage students in HCD in K-16 classrooms (Caroll et al., 2010; Zoltowski, Oaks, & Cardella, 2012), we still lack a general consensus on the terms, practices, scaffolds, and assessments that are needed for us to effectively implement and scale HCD integration. This lack of consensus makes it difficult for researchers, teachers, and policy makers to understand the best practices for implementing HCD in their classrooms, to assess the efficacy of an implementation, or to dive deeply into an implementation for iterative refinement. Given the increased interest in HCD as an approach across the educational spectrum, there is a need to develop a more unified consensus around the terms, practices, scaffolds, and assessments, or we risk a fragmented landscape.

Objectives
The symposium features researchers whose work on implementing HCD across K-16 classrooms focus on: 1) defining the design thinking processes and practices that are associated with HCD; and 2) providing exemplar approaches to integrate and support the teaching and learning of HCD. Lawrence and her colleagues introduce an HCD taxonomy that defines the HCD processes and practices and can inform the design and implementation of HCD curricula. Shehab and his colleagues present a case of integrating HCD in an undergraduate food science capstone course that positively impacted students' knowledge of implementing the HCD processes and using the HCD skills. Dhvani and her colleagues propose an instructional model that integrates the practice of (human-computer interaction) HCI education that takes an HCD approach in K-12 education by outlining the roles and responsibilities of learners and facilitators, prioritizing learner's agency in the process of learning. Lewis and his colleagues present a design and researcher assessment approach for coupled iteration in design that can help students learn to better create designs to meet human needs. Spencer and his colleagues present a researcher assessment approach that assists students in identifying risks in the domains in which they will practice HCD to reduce uncertainty and improve their designs. Royalty and his colleagues propose a reflective tool that can be used to assess and capture how students develop HCD practices. Finally, Goldman and her colleagues show how HCD can also be used by teachers to conduct their own educational design projects to better understand and support their students. Together, these contributions aim to provide a single venue to synthesize the current terms, practices, methods, and assessment of HCD. The symposium aims to develop a coherent and robust understanding of HCD, and its uses in curriculum and instruction, to help frame the field and reduce ambiguity at a critical time in its broader adoption. The symposium also offers methods and assessments that researchers can use to understand the efficacy of their HCD instructional designs.

Session format
The symposium will start with each researcher giving a six-minute talk to introduce the participants and attendees to their work across the symposium's two themes. Next, the discussant will facilitate conversations between researchers on critical issues emerging out of our shared approaches to HCD such as: What are the challenges of integrating HCD in non-design focused curricula, and how can we address them? How do we effectively scale implementation of HCD in K-16 classrooms? How as researchers, do we know if our designs are having the impact we want? Finally, the symposium will close with an open discussion with attendees to identify areas of further research and collaborations that can help us better bring HCD to K-16 education.

Implications
We believe that this session will provide a foundation in a new and growing field. It will solidify the meaning of HCD in order to avoid ambiguity. It will also facilitate the work of researchers and practitioners around the design and implementation of HCD instruction and activities in K-16 classrooms.

Implementation of a Human-Centered Design taxonomy with a novice, multidisciplinary design team
LuEttaMae Lawrence, Saadeddine Shehab, and Mike Tissenbaum

HCD is a problem-solving approach that identifies the unmet need of a population in order to collaboratively and iteratively develop solutions (Brown, 2008). Researchers have studied important components situated in this approach, including iteration (Lewis et al., 2018), sketching (Härkki et al., 2018), and design failure (Yan & Borge, 2020), leaving unexamined how students navigate the overarching approach. While there are well known models that theorize the processes of HCD (Brown, 2008), they do not provide pedagogical guidance that articulates what this learning looks like and how to support it. Therefore, we have developed an HCD Taxonomy that outlines five design spaces (understand, synthesize, ideate, prototype, and implement) (See Figure 1) and practices that describe how students operationalize specific spaces. This taxonomy was designed iteratively with designers, researchers, and teachers from multiple disciplines to develop a flexible tool that can be used across contexts. The goal of this taxonomy is for teachers and designers to develop curricula, learning objectives, and assessments based on what space they are teaching and the practices they want their students to implement. In this case study, we present findings on how the taxonomy emerged during a novice team's HCD approach. Toward this end, we aim to understand how this novice team used HCD practices during their design project.

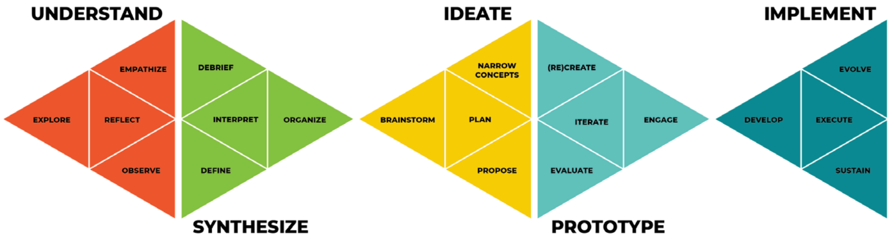

Figure 1. The HCD Taxonomy

We report on a five-week design project from an Introduction to Design Thinking course that teaches students from non-design disciplines about HCD. Three members comprised the design team, a first-year graduate student in education, a senior in civil engineering, and a first-year graduate student in architecture. The instructor assigned a project to select a subculture of which they did not belong and develop three frameworks to address a problem for this subculture. We collected instructional materials, audio recordings of the team's meetings, video recordings of their in-class presentations, and a reflection and post-survey from each team member. We leveraged knowledge integration theory (Linn, Clark, & Slotta, 2002) to analyze the design process and understand how HCD practices can be interconnected to achieve higher levels of integration and can be built over time.

Using our taxonomy and knowledge integration theory (Linn, Eylon, & Davis, 2013), we sought to understand how HCD practices were used by a novice design team and to what extent they made connections across spaces and practices. While this team iteratively used the taxonomy spaces, our findings highlight the challenges of teaching HCD to beginners and the differences among students. Within this group, only one student was able to achieve high levels of integration more than a single instance. We also found that while the group went through the motions of HCD, their process and final results did not always align to the overarching goals. Our paper highlights the complexity and challenges of teaching with the HCD taxonomy, and we share learning considerations to scaffold this process for beginners so that they may achieve higher levels of integration.

Integrating Human-Centered Design in a food science capstone course: A case study

Saadeddine Shehab, LuEttaMae Lawrence, and Mike Tissenbaum

The integration of HCD in post-secondary education can help undergraduate students come up with innovative solutions to authentic and complex problems that are relevant to their field of study (Withell & Haigh, 2013). Lately, there has been some work around the implementation of HCD in undergraduate classrooms (Puente, van Eijck, & Jochems, 2013); nevertheless, much of this work has been mainly reported from a theoretical or design-focused lens, rather than empirical evaluation, especially in STEM disciplines. This case study describes the integration of HCD into a food science capstone course through a) defining HCD and food science learning goals, b) providing scaffolding tools that support students' engagement and learning of HCD, c) creating opportunities for formative assessment and revisions, and d) promoting students' participation and collaboration (Barron et al., 1998). The study explores the students' experiences in this course to provide evidence-informed insights of instructional models that effectively integrate HCD in post-secondary STEM courses.

This study is part of a broader design-based implementation research initiative led by the Siebel Center for Design at the University of Illinois at Urbana-Champaign, which collaborates with faculty members to integrate HCD in their courses. The study took place in an undergraduate food science capstone course in which students solve authentic food science problems while developing novel food products. In Fall 2019, the 42 students who took this course worked in small groups to develop a food product using HCD. Each week, students attended two 50-minute lectures and one 4-hour lab section. The lectures were focused on introducing the students to the different processes and practices of HCD and the principles of food product development. The laboratory sessions were focused on engaging the groups in activities to implement HCD and using the principles of food product development in refining and prototyping their concepts and thinking about the actual implementation of their design in the food science industry.

Pre- and post-surveys were collected from the students to measure the impact of the course on their knowledge of implementing the HCD processes and using the HCD skills, and to assess if the students accomplished the food science learning goals. Classroom observations were collected during the lectures and the laboratory sessions. The video and audio recordings of the students' presentations of their final concepts and their final products were collected from the six consented groups. Interaction analysis of the presentations indicated that integrating HCD in the course helped the groups to systematically approach the development of their food products through empathizing with the users, synthesizing design opportunities, and applying principles of food product development in ideation and prototyping. A paired sample t-test was conducted using students' responses to the pre- and post-survey items and results indicated significant differences suggesting a positive impact of the course on students' knowledge of implementing the HCD processes and using the HCD skills, and that students accomplished the food science learning goals. These findings support the use of an instructional model that can help teachers teach about and through HCD in STEM post-secondary classrooms, including scaffolding and assessment tools.

Embedded design: An approach to support learning of Human-Centered Design practices

Dhvani Toprani, Mona AlQahtani, Yu Xia, and Marcela Borge

Creating learning environments for human-computer interaction (HCI) education for children requires taking a broader perspective towards learning that goes beyond focusing on teaching domain knowledge to include higher-order metacognitive, socio-emotional, and socio-metacognitive skills. However, formal education's emphasis on domain knowledge deprioritizes engaging learners in learning about and practicing these higher-order skills, making it challenging to integrate HCI education into K-12 (Collins & Halverson, 2018; Duschl & Bismark, 2016). Within an increasingly connected world, HCI designers require to not only know but also practice sophisticated thinking processes (Carroll, 2013). Building upon previous work on instructional support for children to iterate and solve ill-structured, real-world design problems (Collins et al., 1991, 1989; Jonassen 2000), and integrating HCD approaches we propose an instructional model, i.e., embedded design framework, for designing learning environments that foster higher-order skills to integrate HCI education into K-12 (Borge et al., 2020). The goal of embedded design is to create human-centered learning environments that focus on teaching through practice where learners have the agency to craft their learning experiences.

This framework is developed from an ongoing research project with eight to twelve years old children in an afterschool club, where children engage with playful design challenges within an HCI context. Children worked in groups of three, using different technologies like Lego, Minecraft, and Makey-Makey. Each session was structured to give children forty-five minutes to do hands-on designing with their group members, and the instructors used ten to fifteen minutes at the beginning and end of the session for whole-class discussion to introduce the design challenge and reflect on groups' design and collaborative processes.

As an instructional tool, embedded design framework proposes six core principles for facilitators and learners (See Table 1). These principles emerge from case studies drawn from one year of the afterschool club data. It embraces learners' agency by allowing their experiences and needs to be the main driving force of community rules, future discussions, and activities. As needed, facilitators observe learners and create perspective shifting opportunities to help learners discern complex concepts. They provide learners with activities where they can take over different roles within an HCI design context as both users and designers. Facilitators take over the role of orchestrators as they engage learners in reflective discussions where they help them recognize their needs as well as the needs of others in their community. As a community and across time, facilitators work as connectors of experiences as they help learners make sense of previous events in relation to current and future ones. In doing so, community experiences become objects to reflect on, making abstract concepts accessible and attainable by learners.

Table 1: Principles of Embedded Design and the Roles and Responsibilities of Learners and Facilitators.

Principles	Roles and responsibilities
Learners as Agents, Actively Participating in Domain Thinking Processes	
Learners as primary learning agents	Learners spend the majority of the time in control of their own learning experiences. They work on self-directed projects with peers, making collective decisions about what they will design and how they will spend club time.
Learners as central participants	Learners are taking an active role in different aspects of design, even during expert modeling, by playing an important complementary role that the expert must interact with, i.e., user for the designer, builder for the planner, etc.
Learners as anchors of the sense-making & solution process	Learners' perspectives/feelings during the process of design anchor collective sense-making during reflection. These concrete experiences are used as objects of thought to understand problems and devise solutions.

Principles	Roles and responsibilities
Facilitators as Learning Designers, Orchestrating Co-Construction of Knowledge	
Facilitators as creators of perspective shifting events	Facilitators create opportunities for learners to experience a design event from different perspectives, i.e., the learner takes on the role of designer receiving feedback from potential users and then takes on the role of a potential user providing feedback to the designer.
Facilitators as orchestrators of ongoing reflection	Facilitators lead reflective activities where the facilitator prompts learners to share their thoughts, feelings, and concrete experiences; learners' contributions are used as a means to connect the situated practice to expert practice, help learners identify important expert practices and existing problems in their own practices, and to understand why these problems occur. Facilitators also help learners to understand and develop shared goals and concrete plans for improving existing practices.
Facilitators as connectors of experiences	Facilitators observe learner activity, taking notes on important topics to discuss and analyze during community reflections. Individual and team experiences are shared with the community to develop shared understanding of important processes, dispositions, and values embodied by different experiences. These shared experiences can then be used as shared references to make sense of future events.

Embedded design contributes to the practice of HCI education that takes an HCD approach by outlining the roles and responsibilities of learners and facilitators, prioritizing learner's agency in the process of learning. By prioritizing agency, the higher-order skills required for HCI education are learned around the authentic experiences of the learner, giving them the opportunity to practice these abstract skills rather than learning it as technical knowledge. The six principles outlined within embedded design are developed with the aim of helping educators redesign their learning environments of HCI education by giving agency to children and broadening our perspective of learning.

Planning to Iterate: Designing to support and assess iteration in design

Daniel Rees Lewis, Spencer Carlson, and Matthew Easterday

To meet the needs of the stakeholders they are designing for, HCD students must learn how to iterate effectively. Iteration is a vital practice because real-world design problems are highly ill-structured, with "ambiguous specifications of goals, no determined solution path, and the need to integrate multiple knowledge domains" (Jonassen 2000, p. 80). To create solutions that support stakeholder needs, expert designers conduct *coupled iterations* in which they simultaneously (a) learn more about the nature of the problem, including stakeholder needs, (b) learn more about the extent to which their design is effective in addressing the problem, and (c) change the design in accordance with what is learned (Adams, Turns, & Atman, 2003). In short, we argue that if we are not supporting students to continually apply what they have learned about their problem, stakeholders and current design to their future design, we are not teaching them the core skill in HCD.

We present Planning-to-Iterate (Rees Lewis et al., 2018), a design and researcher assessment approach for coupled iteration in design. Planning to Iterate supports iteration by (a) facilitating discussions and prompting teams to conduct a planning process of representing the problem, prioritizing unknowns, and making iteration plans; (b) using two templates, the design canvas and iteration plan; (c) providing and prompting use of guiding questions that drive students to consider common pitfalls, and examples.

We created the assessment in Planning to Iterate for researchers to understand the extent teams are conducting coupled iteration—that is, to what extent are teams gathering information on problems and solutions to inform revisions to their design. Assessment involves videoing and analyzing weekly student Planning to Iterate sessions. We analyze weekly student planning through applying three codes in video analysis: (a) *problem learning* which to capture team reports of learning about aspects of the problem, (b) *solution learning* which captures reports of learning about the design, and (c) *solution revision* to capture reports of plans to change the solution based on reported learning. We code for teams conducting coupled iterations when problem learning (code a) and solution learning (code b), informed solution revisions (code c).

Our goal with Planning to Iterate has been to create scaffolds and assessments for supporting coupled iteration. Initial work in Planning to Iterate shows that compared to a far more intensive face-to-face coaching, student design teams supported by Planning to Iterate conducted more coupled iterations and created more effective designs (Rees Lewis et al., 2018). In doing so, we can help students learn to better create designs to meet human needs.

The Design Risks Framework: *Risks* as a key learning goal in Human-Centered Design

Spencer Carlson, Daniel Rees Lewis, and Matthew Easterday

Iteration is the strategic management of the design process to refine one's understanding of the problem and advance a solution (Adams et al., 2003). As such, iteration is a defining characteristic of effective design processes (Adams et al., 2003; Crismond & Adams, 2012). Design practitioners recognize that effective iteration requires designers to identify *risks*—gaps in their knowledge of the problem stakeholders, and the current design that could lead them to design something that does not support stakeholders' needs—so that they can plan iterations in which they learn more about those unknowns and update their design solution if necessary (Bland & Osterwalder, 2019). While this skill is of general importance across design domains, the underlying knowledge varies by domain. For example, toy designers must learn to identify the risk that their toy might be a choking hazard while social media designers must learn to identify the risk that their platform might radicalize users.

We must teach students to identify risks in the domains in which they will practice HCD. This requires assessment methods to measure students' ability to identify risks in a given design domain. We present the Design Risks Framework (Carlson et al., 2018), a researcher assessment approach for identifying risks in HCD. In this approach, students construct an external representation of their knowledge about the problem, stakeholders, and their current design. Then, students attempt to identify risks by reflecting on the gaps in their knowledge that could lead them to design the wrong thing. Next, a researcher with design expertise (or a design instructor) reviews the students' problem representation to identify risks. Last, the researcher compares the risks they (or the instructor) identified, with those the students identified. This allows researchers to measure students' ability to identify risks in their projects relative to that of an expert. Over time, this method also enables researchers to develop a list of the key risks that students must learn to identify in a given design domain—thereby defining in detail a critical learning goal for HCD learning environments in that domain. This list could be used to create rubrics or checklists that instructors might use for formative assessment of students' ability to identify risks.

Our goal with the Design Risks Framework has been to assess students' ability to identify risks in specific design domains. In initial work assessing novice designers completing service design projects, researchers used the Design Risks Framework approach to assess a large number of domain-specific risks that students struggled to recognize in their projects (Carlson et al., 2018). By focusing on risks as a key learning goal in HCD, we can help students learn to plan iterations to reduce uncertainty and improve their designs.

Reflective Design Practice: A novel tool that captures how students develop Human-Centered Design practices

Adam Royalty, Helen Chen, and Sheppard Sheri

Learning HCD in a university setting can be "messy." Students often work in project teams on ambiguous problems (Goldman et al., 2012). In short order each project unfolds in a unique way, making understanding student growth difficult. This work utilized a tool for capturing students' design work. Furthermore, we analyzed this design work and found three ways in which students internalize the methods and mindsets of HCD.

The results come from a study of 33 students from five schools within a large U.S. research university who took a 10-week introduction to HCD course. The data were gathered using a novel digital reflection tool called Reflective Design Practice (RDP) which allows students to capture authentic work and reflect upon it longitudinally (Royalty, Chen, & Sheppard 2018). RDP prompted participants to photograph an artifact they created in their HCD course each week. The artifact could be tangible (e.g. a physical prototype) or it could be intangible (e.g. an interview protocol). For each artifact, participants were given questions to help them reflect on their creation. Participants uploaded the artifact and the associated reflections to an online folder—forming a multi-page portfolio of design work. After seven weeks, researchers conducted a semi-structured interview with each participant based on their weekly reflections. We used a grounded theory approach to analyze the weekly reflections and the interviews. The aim was to distill how students linked their own perceived growth to the academic environment in which they learned design.

The data suggest three general categories for student sense making. Supports for Learning Design are specific details of the academic environment students identified as supporting how they learn design and transfer that situated learning (Greeno Moore & Smith 1993). Self-Differentiation of Design are aspects of the academic environment that shape students' perspective of what design is and what design is not. Many of these realizations come from contrasting design work with work performed in other courses. Student Responses are the cognitive and emotional responses to design instruction that shape how students develop their own design practice.

Although Student Responses are internal, they develop through working repeatedly within the academic environment. Each general category has between five and eleven sub-categories. These initial findings can help researchers and practitioners better understand how students construct their own HCD practice. It may be the case that students learn HCD in ways that instructors do not perceive or account for.

Empathy development in design thinking for improving access and equity for students designated as English learners

Shelley Goldman, Annie Camey Kuo, Kimiko Lange, Melissa Mesinas and Rose K. Pozos

Design thinking during HCD begins with understanding a problem holistically and from the eyes of the people for whom one is designing and iterates with cycles of prototyping and feedback (Goldman & Kabayadondo, 2016). We report on a three-year, four school district research practice partnership (RPP) (Coburn, Penuel, & Giel, 2013) to use design thinking with K-8 teachers and administrators to design solutions for supporting students designated as English learners (DELs). As of 2018, DELs comprise approximately 19.3% of public school students in California (McFarland et al., 2019). DELs are present in nearly every district, yet not all schools serving DELs have specialized teachers or resource programs. The districts in our study lacked specialized supports for DELs and had low numbers of DELs (10% or less), a situation not yet addressed by research or policy.

Our RPP employed design thinking in conjunction with hybrid professional development workshops (Rutherford-Quach, Kuo, & Hsieh, 2018) to help teachers and administrators build capacity for understanding and supporting DELs. The goal was to raise collective awareness of, and attention to, systematic educational inequities surrounding DELs such as social isolation and lack of specialized language learning services, and to support teachers and administrators in designing change to many aspects of their DELs' experiences.

Empathy development was a key component of the training and the design thinking approach. The educators generated 18-24 solutions for students each year. We relied on empathy exercises with teachers throughout the design thinking process. HCD work stretched throughout the design process and was especially evident during prototyping, feedback, and iteration cycles. Resulting designs ranged from new classroom languaging strategies, to relationship building, to reorganizing specialized staff, to focused professional development. The designs were responsive to individual students and small groups, whole classes, and district and structural systems.

Data were gathered using an ethnographic approach, with documentation of the participants' design processes, with a goal of capturing small changes in practice and mindsets over time. We administered pre- and post-year surveys, collected field notes, written artifacts from participants, video and audio recordings of meetings, and focus group reflections. The role of empathy and the attention to students' needs in the designs turned out to be a key factor in effective design projects. We present an analysis of survey results and resulting educator design project analyses to show how the empathy orientations impacted educators' work on behalf of students. We identify connections between the empathy work educators completed and their perceptions of their DEL students' abilities (e.g. exhibiting asset-based rather than deficit-based views) and achievements (being situated in the system rather than in the children). Findings show robust changes in classroom instructional practices, a few examples of systems change, and uneven awareness of and attention to inequitable social and educational access for DELs. Empathy was essential to the progress that was made.

Creation of an Inventory Assessing Epistemic Beliefs about the Co-Construction of Knowledge in Team Science Contexts

Erica D. Kessler, University of Memphis, dgrisham@memphis.edu
Jason L. G. Braasch, Georgia State University, jbraasch@gsu.edu
Deborah Tollefsen, University of Memphis, dtollfsn@memphis.edu
Chrysanthe Preza, University of Memphis, cpreza@memphis.edu

Abstract: Scientific collaboration is necessary as research grows increasingly more complex. Research focusing on the Science of Team Science (SciTS) seeks to better understand and facilitate collaborative research in science. The current work provided new empirical understandings on epistemic beliefs about group knowledge or how a group collectively comes to know something by developing the Epistemic Beliefs about the Co-Construction of Knowledge (EB-CCK) inventory. Using exploratory and confirmatory factor analyses, the present study established an 18-item inventory composed of two factors: one capturing a more collaborative mindset and one capturing a more individual mindset about the co-construction of knowledge. Limitations and future directions are discussed.

Introduction

Science is inherently a collaborative affair. During every stage of the research process, scientific research involves working together with others, both within and across respective fields of study (Jonassen, et al., 2006). As issues in empirical research grow more complex and sophisticated, so does the need for collaborative teams of researchers that are fundamental to the future of scientific understandings, and in ensuring the use of rigorous, yet diverse methodologies (Falk-Kresinski, et al., 2010). Although interdisciplinary scientific collaboration appears to undergird many important research findings over the past several decades, scientists do not always employ the best practices for collaborate one another, which can undermine success. To compound these potentially problematic issues, scientists are mostly trained extensively within their respective disciplines, and not on the most effective and efficient ways to collaborate with scientists in other disciplines (Jonassen et al., 2006). Thus, there is a need for educators to promote interdisciplinary collaborative problem-solving skills in the classroom, due to the assumed benefits of training students to work in a collaborative manner with colleagues in other disciplines (Graesser, et al., 2018).

Current research

To measure Epistemic Beliefs about the Co-Construction of Knowledge (EB-CCK). we 1) developed initial scale items and used exploratory factor analyses on two samples to investigate factor structure; 2) confirmed our anticipated factor structure using two additional samples; and 3) examined the validity of the EB-CCK. Across two studies with 1373 participants, an 18-item inventory composed of two factors, one reflecting that team science should be more collaborative and a second that it should be more individualistic, were identified.

Discussion

The current study sought to create a measure that assesses an individual's epistemic beliefs about the co-construction of new knowledge in team science contexts via exploratory and confirmatory factor analytic techniques. Given no studies to date have attempted to create a measure regarding epistemic beliefs about the co-construction of new knowledge in team science contexts, the present work hopes to inform current policies that seek to train students and scientists on the best practices for group collaboration in scientific research.

Personal epistemology or personal epistemic beliefs have been studied and found to guide how individuals interact with knowledge and information (Hofer, 2000; Kardash & Scholes, 1996; Pieschl et al., 2008; Strømsø et al., 2008). While extant epistemic beliefs inventories focus on the individual's acquisition of new knowledge and ways of knowing, we hope the EB-CCK can provide a nuanced understanding of how an individual's beliefs about the co-construction of knowledge can influence their behaviors related to group collaboration. When an individual answers questions about their own personal ideas related to knowledge and knowing, responses do not necessarily reflect their views about knowledge and knowing in a group setting. For example, an individual may believe that knowledge is ever-changing and can be increased with learning and effort. However, this same individual may not feel that knowledge or coming to know something in a group setting is productive, perhaps instead endorsing that an individual can achieve more knowledge than a group. This element of epistemic beliefs may be more predictive of collaborative efforts in scientific research, thus supporting the utility of questionnaires like the EB-CCK.

Factor 1: Collaboration

Obviously, when looking at how groups collaborate, their beliefs about and approaches towards collaboratively creating knowledge is imperative. The first of the two factors identified in the current work consisted of items that reflect a more collaborative view on the construction of knowledge in groups. Examples of items that reflect the collaborative factor include: *"When scientists find conflicting results, the differences can help to further refine theories"*, and *"The production of knowledge in a scientific domain requires the help of multiple scientists"*. These items all reflect an individual who may work in a more collaborative manner with others to provide better empirical understandings of scientific findings.

An individual who scores highly on the collaboration factor of the EB-CCK may be better suited for working efficiently and effectively in collaborative group science contexts. For example, these individuals may value new methods of research that reflect a combination of techniques from multiple disciplines, thus creating approaches that may function above and beyond the sum of the parts. Additionally, researchers are often faced with conflicts or contradictory findings in science, and an individual who is open to exploring these areas of conflicting information may come to better understand the topic as a whole. Personal beliefs that scientific research is best conducted under the umbrella of collaboration are not only beneficial for the individual's understanding of how a group comes to know something but also for the entire scientific community as we move towards more transdisciplinary approaches to conducting research. As Fiore et al. (2018) explain, some areas of research require collaboration as core research questions become more and more complex. In order to progress towards more sophisticated research practices, teams of individuals with more collaborative mindsets could produce more innovative, successful outcomes. Stokols et al (2006) suggest that strong leaders, especially those with a "collaborative orientation" could not only facilitate group research efforts but may also demonstrate management skills within the group when necessary. Perhaps the EB-CCK can help to identify individuals that endorse collaborative orientations and, by doing so, aid in the construction of groups of scientists who not only collaborate but collaborate *well* together.

Factor 2: Individual

Although individualist mindsets may be beneficial in some learning situations, they may undermine efficient and effective group collaboration. The second of the two factors identified in the current work is composed of items that reflect a more individualistic view on the construction of knowledge in a group setting. Example items include: "*Science works best if each scientist sticks to the methods he/she knows"*, and *"The production of knowledge in a scientific domain is best done by a solitary researcher working independently of others"*. These items reflect that an individual may find group collaboration to be ineffective or unnecessary when constructing knowledge or coming to know something, not valuing the potential synergy that could arise from more collaborative approaches.

An individual who scores highly on the individual factor of the EB-CK may struggle to accept or help create new knowledge in team science collaborative settings. For example, if someone in the team believes that scientific research is best conducted by an individual using the techniques in which they are familiar, their contributions in a collaborative setting may be ineffective or absent altogether. Graesser et al. (2018) explain that collaborative research may be threatened by an individual group member that is disengaged and/or unskilled when collaborating with others. Identifying those individuals who could potentially undermine successful collaborative research could help streamline scientific collaboration altogether, while also serving as a point of belief remediation for graduate student mentors, employers, and the like.

The emerging field of SciTS has assisted in the progression of our scientific understandings of collaborative research by acting as a catalyst for collaborative research itself. It is the hope of the current research that a measure of Epistemic Beliefs about the Co-Construction of Knowledge will provide additional insight into the promotion of collaborative research across and within various fields of research.

Investigating Perseverance Improvement in Secondary Mathematics Students

Joseph DiNapoli, Montclair State University, dinapolij@montclair.edu

Abstract: I examined the perseverance in problem-solving of 30 secondary students as they engaged with challenging mathematical tasks over six weeks. Their perseverance improved, primarily due to consistent opportunities to record their conceptual thinking at the outset of their engagement. These artifacts of their thinking often helped prolong their productive efforts upon impasse and improved their selection of problem-solving strategies and affect regulation.

Supporting and improving perseverance in problem-solving

Perseverance with challenging ideas is an essential process for learning with understanding. In the context of problem-solving, perseverance is initiating and sustaining in-the-moment productive struggle in the face of mathematical obstacles, setbacks, or discouragements (DiNapoli & Miller, 2020). Supporting in-the-moment student perseverance has been made explicit as a way of improving mathematics education, with the expectation that such support will nurture students' perseverance to improve over time. This demand has widened the assumptions about what can constitute mathematical learning. The process of perseverance, long viewed as solely an affective or supporting component to mathematical learning, can now be simultaneously viewed as an outcome measure capable of development and improvement, alongside more standard summative achievement.

Many research studies have sought to detail classroom activity that supports student perseverance with challenging mathematics, yet little is known about how such practices can help improve student perseverance in specific ways over time. In general, research shows that providing consistent opportunities for students to engage with unfamiliar yet complex tasks encouraged more variability in problem-solving strategies and greater learning gains, compared to providing consistent opportunities to engage with more routine mathematics (e.g., Warshauer, 2015). Students need support and feedback, however, to help facilitate metacognition and creative problem-solving during times of frustration (e.g., Bass & Ball, 2015). A recent study found that when secondary students created artifacts of their personal conceptualization of a mathematical task prior to problem-solving, they could better self-regulate their efforts at times of impasse and continue to persevere (DiNapoli & Miller, 2020). Without recording their conceptual thinking at the outset, these students felt frustrated after a setback and often gave up without making an additional attempt at solving.

Despite the recent research to uncover ways to support student perseverance at moments of struggle, questions remain about whether these practices help foster student perseverance to improve over time. Research on perseverance in problem-solving can produce insights into effective practices by which to learn mathematics with understanding, yet much of the empirical evidence of student perseverance have been situated in single points of time with little or no exploration of how those perseverance experiences may be related or demonstrate signs of specific improvement. Therefore, the purpose of this study was to address these lingering concerns about whether and how student perseverance, when supported properly, can improve over time.

Methodology

The participants of this study were 30 ninth-grade students from two algebra classes with the same teacher in a Mid-Atlantic state. These participants were purposely chosen to have demonstrated, via pretest, the prerequisite knowledge necessary to initially engage with each task included in the study.

To collect data, each participant was observed engaging with five low-floor/high-ceiling mathematical tasks, one per week. For each participant, three tasks were randomly chosen to be scaffolded (i.e., prompting participants to record an artifact of their conceptual thinking at the outset), and two tasks were randomly chosen to be non-scaffolded (i.e., no such prompt). Each participant worked on these set of five tasks in a random order. I conducted problem-solving interviews, video reflection-interviews, and an exit interview with each participant.

To analyze data, I used the Three-Phase Perseverance Framework (3PP) (DiNapoli & Miller, 2020) to capture if the task at hand warranted perseverance for a participant (the Entrance Phase), the ways in which a participant initiated and sustained productive struggle (the Initial Attempt Phase), and the ways in which a participants re-initiated and re-sustained productive struggle, if they reached an impasse as a result of their initial attempt (the Additional Attempt Phase). All coding decisions (or whether or not certain engagement constituted evidence of perseverance) depended on student cues from all interviews. I also calculated 3PP scores based on demonstrated perseverance per task; 3PP scores ranged from 0 to 12, depicting minimal to optimal demonstrated perseverance in this context, respectively.

Results and conclusions

Overall, participants' perseverance across mathematical tasks improved over time, more so on their scaffolded tasks than on their non-scaffolded tasks. Participants' demonstrated perseverance on their three scaffolded tasks improved in quality over time as evidenced by increasing mean 3PP scores (see Figure 1). Participants' demonstrated perseverance on their two non-scaffolded tasks also improved in quality over time (see Figure 1). However, the average rate at which participants' scores on their non-scaffolded tasks improved was over two times less than the rate of improvement of scores on their scaffolded tasks. All 30 participants affirmed in the Entrance Phase of the 3PP that they understood the objectives, but did not know how to solve each task. Also, all 30 participants reported a perceived impasse as a result of their engagement with each task.

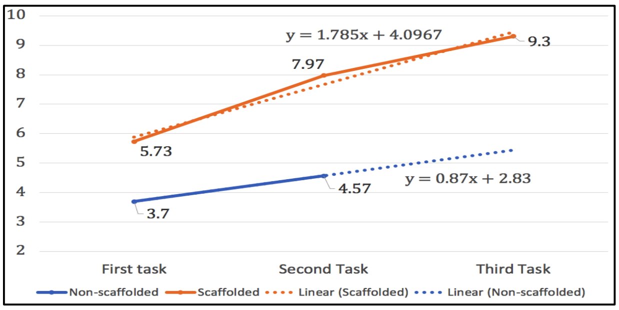

Figure 1. Mean perseverance scores over time and by scaffold condition.

There is also qualitative evidence to suggest that the task scaffolds were helping participants improve their perseverance over time. Considering all interview data, participants reported personal improvements they noticed, over time, about their engagement with the tasks in the study. Most participants (83%) mentioned they thought they were getting better as they had more practice with these types of problems. Several participants (63%) mentioned their improved work on tasks specifically prompting them to conceptualize the situation prior to starting (i.e., their scaffolded tasks). Arguably the most noticeable improvement, from the participants' point of view, was affective in nature. Many participants (73%) explained in their exit interview that they felt like they were getting better at handling the stress of the situation as they reached impasses within their work on mathematical tasks they did not know how to solve. Some participants (40%) reported cognitive gains: the ways they were thinking about the mathematics and their problem-solving abilities were improving.

These results suggest that developing students' perseverance for solving challenging mathematics tasks may be possible through the process of deliberate practice, a systematic effort to improve performance in a specific domain (Ericsson et al., 1993). Through this study's design, participants essentially deliberately practiced to improve their perseverance. They worked toward specific objectives of challenge, demonstrated appropriate prior knowledge, invested their full effort and attention to make progress on these tasks (relying heavily on self-control to not give up at moments of impasse and continue to persevere), were a self-source of feedback when recognizing a setback and modified their efforts accordingly, and had opportunities to repeat and practice working through these processes every week. With their scaffolded tasks, this repeated opportunity helped students refine their strategies over that time to learn to persevere in more effective ways. Although students also had a chance to repeat the processes of deliberate practice with their non-scaffolded tasks, the data showed that they did not refine their strategies in the same high-quality ways as they did with their scaffolded tasks. This lack of transfer should motivate future research to investigate conditions that may support students to incorporate these conceptualization practices into their normative problem-solving repertoire.

Cognitive Load Measurement Using Two Kinesthetic-Based Methods: Rhythmic Tapping Method and Tactile Detection Response Task

Kevin Greenberg, University of Utah, kevin.greenberg@utah.edu

Abstract: Cognitive load theory has struggled to develop a modality-unspecific method of measurement, that being a secondary task which measures overall cognitive load rather than only auditory or visuospatial processing. The current study compares two kinesthetic-based methods, the rhythmic tapping method (RTM) and the tactile detection response task (TDRT) in relation to their modality specificity. The methods were examined in relation to the degree of modality specificity they had with auditory and visuospatial working memory processing, via separate n-backs in each modality. The findings indicated the RTM may be modality specific. The RTM was found to have greater interference with auditory working memory processing compared to visuospatial processing. There was evidence the TDRT may be modality-unspecific, as the method had parallel interference with auditory and visuospatial working memory processing.

Introduction and background

Cognitive load theory (CLT) is one of the most used frameworks in learning sciences (Park & Brünken, 2015; Sweller, 2018). A goal of the theory is to provide practical implications for instructional design to facilitate learning by promoting schema acquisition through efficient use of limited working memory resources (Baddeley, 2012). However, CLT has struggled in developing a method to measure cognitive load. John Sweller, who formulated CLT, states "Attempts to find a sufficiently sensitive measure are ongoing" (2018, p. 4), with sensitivity referring to the measures capacity to validly detect changes in overall cognitive load. A promising course is the use of secondary task, which have been used in psychology to study a variety of cognitive capacities, such as working memory (Baddeley, 2012) attention during driving (Stojmenova, Jakus, & Sodnik, 2017), and cognitive load in the field of educational psychology (Park & Brünken, 2015).

In educational psychology, the use of secondary tasks for cognitive load measurement has been less than optimal as most methods are modality specific. The term modality specific refers to a measurement method that can only provide a measure of cognitive load for processing in one modality, rather than total cognitive load (Baddeley, 2012; Park & Brünken, 2015). The current work will study two kinesthetic-based measurement methods to examine the modality specificity of each secondary task in relation to auditory and visuospatial working memory processing. The is aim to empirically examine if the two kinesthetic-based methods of measurement are modality unspecific. The two tasks are the rhythmic tapping method (RTM) is a recently developed secondary task that requires participants to respond by tapping their foot to a specific, internally-driven rhythm. The other task is the tactical detection response task (TDRT) is a secondary task, developed by the International Organization for Standardization (ISO) (ISO, 2016). However, the methods have yet to be systematically compared in relation their modality specificity. The goal of the present work is to examine the degree of modality specificity the RTM and TDRT have with auditory and visuospatial processing.

Methodology

Participants

Participants were recruited from undergraduate courses at a large research university in Western United States. The preliminary analysis consisted of 41 participants (M = 22.56, SD = 7.18).

Instruments

Modality specific working memory tasks

The working memory tasks were the auditory n-back and visuospatial n-back, each being a 2-back. Participants completed three blocks for each condition (approximately three minutes). The tasks were administered using the software PsychoPy3.

Secondary tasks

The TDRT used the ISO 17488 system and software. The vibrating buzzer was placed on the participants collarbone and responses were recorded via a foot tapping device. Performance was measured by accuracy and RT. The procedure from the RTM was the same method used in the study that developed the instrument (Park & Brünken, 2015). Performance on the RTM consists of an intra-individual analysis that computed the mean rhythm for the baseline condition that was compared to the mean rhythm in the n-back + RTM conditions. The tapping was recorded by the software, Audacity version 2.3.2.0.

Procedure

After participants voluntarily consented to the research, they filled out a demographic questionnaire followed by a practice of the auditory n-back and visuospatial n-back. The experimental trials consisted of each n-back (order-counter balanced by modality) accompanied with each secondary task or no secondary task (order counter-balanced). For instance, one participant could do the n-backs with no secondary task, then the n-backs with the TDRT, lastly, the n-backs with the RTM. For the n-back conditions with the secondary tasks, the participants received training and completed the baseline for each secondary task immediately prior to performing the concurrent n-backs. The study took approximately 45 minutes. Participants received 1 credit for course research hours for their participation.

Results and conclusion

There was a main effect of the RTM on n-back accuracy, $F(3, 119) = 8.01$, $p < .001$. The auditory n-back + RTM had a significantly lower accuracy compared to both the baseline auditory ($z = 4.39$, $p < .001$) and the baseline visuospatial n-back ($z = 3.80$, $p < .001$) accuracies.

There TDRT had a main effect on n-back accuracy, $F(3, 120) = 7.50$, $p < .001$. Visuospatial n-back + TDRT had a significantly lower accuracy compared to both the baseline visuospatial n-back ($z = 3.68$, $p < .001$) and the baseline auditory n-back ($z = -4.10$, $p < .001$) accuracies. Also, auditory n-back + TDRT had significantly lower accuracy compared to the auditory n-back baseline accuracy ($z = 2.70$, $p < .001$).

The RTM had a determinantal effect on auditory working memory processing, but not visuospatial processing, meaning the RTM may be modality specific for auditory processing. The findings could reflect the RTM requires more auditory processing in order to tap to the internally-driven rhythm. The TDRT had equal interference with both auditory and visuospatial processing, which suggests this method may be modality unspecific. The modality-unspecific nature of the TDRT may be due to the minimal attentional resources needed to monitor the TDRT stimulus. The findings are important for measurement of cognitive load as the TDRT may be a new, modality-unspecific method to measure the construct.

Identifying and Responding to Process Failures in Problem-solving

Tanmay Sinha, ETH Zürich, Switzerland, tanmay.sinha@gess.ethz.ch

Abstract: Learning from failure is a vital skill. One aspect of failure that has received little empirical attention, however, is its process-focused nature and how technology interventions might benefit from this understanding. I present a conceptual framework for (a) identifying process failures via thin-slice methodology, and (b) responding to process failures by building on the idea of regulative loop systems, but with additional emphasis on psychological mechanisms describing causes (and remedial pathways) of process failures.

Introduction

Failure in empirical research in educational psychology is typically defined in relation to a desired goal (e.g., scores on a posttest) and reflects an *outcome-focused* viewpoint of designing for learning. In tasks with high failure-likelihood, terminal failures are but naturally contingent on individual *problem-solving actions* en route to developing a solution. These actions can comprise, for instance, selecting and executing appropriate problem-solving operators that allow making tractable and meaningful progress through a problem, as well as monitoring and reflecting on intermediate outcomes to revise solutions. I conceptualize among such actions, those that might constrain the affordances available for task progress and block, disrupt or alter routes to immediate recovery (progress towards the canonical solution), as *process failures*.

Study context

I use as study context the learning design of problem-solving followed by instruction (PS-I), where students are given opportunities for the generation of multiple representations and solution methods before being formally exposed to the targeted concepts (Loibl, Roll, & Rummel, 2017). To illustrate the conceptual framework for identifying and responding to process failures in the current article, I will use video (face and screen) recordings of a convenience sample of $N = 4$ participants (60 minutes of problem-solving data). This convenience sample is randomly chosen from a controlled lab study reported in Sinha & Kapur (2021), where $N = 132$ university students (59% male, $n = 78$; 41% female, $n = 54$) participated in a PS-I intervention in the domain of introductory data science. The learning objective was to help students understand the complementary importance of numerical and graphical representations when reasoning with data.

Identifying process failures

Person perception research has demonstrated that thin-slices, or judgments of others based on *brief exposure* to their behaviors (Ambady, 2010) give an accurate assessment of several ecologically valid outcomes. I adopted such a *thin-slice* approach for coding process failures, defined as moments of struggle during the problem-solving process that cause a delay or a pause in learning (Warshauer, 2015). Two video streams, including the frontal view of the face (and upper body) and the screen recording of students' problem-solving actions in the learning environment, were juxtaposed to allow for rating of the level of struggle for each 60-second video segment (thin-slice). The first, middle and last five minutes of the problem-solving phase from the convenience sample was used as the coding stimulus (totaling 15 X 4, or 60 one-minute thin-slices). Two raters were used to allow computation of reliability metrics. The presentation order of these thin-slices was randomized within as well as across all five-minute segments. Raters chosen for the coding of process failures were well-versed with conceptual tasks associated with the problem-solving environment, and went through a brief training session in recognizing prototypical facial expressions of affect. The presented prompt asked raters to rely on gut instinct to make judgments – "how struggling does the participant appear to be?". Post-hoc (that is, after completing all ratings), raters were asked to summarize what led them to rate an episode with a certain intensity of struggle. The quality of results obtained during the iterative coding process were used to adjust the rating scale and time-window. After resolving disagreements and achieving high enough inter-rater reliability ($\kappa = 0.76$), the ratio of thin-slices where students were adjudged to be struggling ($n = 21$) versus where they were merely on-task (low levels of struggle, $n = 39$) was roughly in the ratio of 1:2. *High struggle problem-solving episodes* involved observable behaviors such as writing programming code that led to error messages followed by episodes of debugging, re-running same code several times, scrolling up and down the learning environment without necessarily focusing on a particular comparison and contrast, confused facial expression (brows furrowed, eyelids narrowed), confused smile, leaning back and/or shaking head, etc. *Low-struggle problem-solving episodes* mainly involved on-task behavior where students appeared to be engaged with a neutral facial expression and performed required operations like writing programming code, seeking syntax-specific help as needed, etc. To argue for the *meaningfulness* of the coded episodes of struggle, I also looked at empirical data (see Sinha & Kapur, 2021for details) for the $N = 4$ participants with thin-slice coding. These case studies can be found at https://www.tinyurl.com/SMSinhaISLS2021.

Responding to process failures

Having demonstrated a plausible coding approach for identifying process failures, it is imperative to work towards designing appropriate response strategies for educational technology interventions, in the service of facilitating positive effects and mitigating the negative effects of process failures (Figure 1). Here, I draw on ideas of *regulative loop systems* (VanLehn, 2016), in particular focusing on a particular genre of regulative tasks (that is, *coaching*) that uses the comparison between observed and desired student *behaviors* to generate remedial scaffolding. What is conceptually novel with respect to these previous strands of work is the explicit addition of a theoretically-grounded layer of *functions*, or psychological mechanisms underlying process failures, which are intended to serve as a basis for scaffolding via an educational technology (rather than basing scaffolding directly on the observed behavior). This addition presupposes that design-based researchers choose intervention strategies tightly coupled to the causes of particular kinds of process failures (drawing on theoretical research), and consequently monitor a specific corresponding set of observed behaviors to decide when to intervene. More generally, the plea is to embrace a more holistic view to understanding *why* specific instantiations of process failures arise and *what can be done* about them in interventional terms. Further details and example walk-throughs are present at https://www.tinyurl.com/SMSinhaISLS2021. Note that there exists a many-to-many mapping between different layers of the framework and although I focus on educational technologies, this framework is applicable for teachers too. The ideas presented in this brief article are part of a larger research effort to understand the scaffolding of failure-driven learning, and to use that understanding to implement a technology-supported learning environment that can (ideally) assist students in (a) reducing floundering before, during, and after process failures, (b) anticipating future process failures better, and finally (c) maximizing learning after process failures.

Kitchen Science at Home: Engaging Pre-School Children through Distance Education during Covid-19 Quarantine

Loucas T. Louca, European University Cyprus, L.Louca@euc.ac.cy

Abstract: This is a case study describing the ways I engaged a group of 20 5-6,5-year-old children in an afternoon, distance, science education unit investigating snails. The study took place during the Covid-19 quarantine time in Spring 2020. The paper demonstrates the transferability of pedagogical ideas usually implemented in the face-to-face classroom. It also illustrates pedagogical ideas that were more productive to use during the online unit. Lastly, it describes the development of an online learning community that included children and parents.

Keywords: distance education, pre-school science education, emergency response teaching

Introduction

In Spring of 2020, COVID-19 pandemic confronted educators worldwide with a series of unprecedented challenges (e.g., Whittle et al., 2020). Educators were "forced" to use distance education (DE) approaches as a response to wide-scale educational shutdowns. Despite their wide use, many educators were reluctant to use DE approaches with young children, due to the fact that this age group may not be accustomed of using DE tools fluently, productively and independently, since they usually need their parents' input to participate in technology-mediated learning from home.

Methods, data sources and analyses

This is a descriptive case study (Yin, 2017) presenting a 3-week DE science unit investigating snails with a group of 20 5-6,5 year-old children voluntarily participating at a STEM education, afternoon on-line club. In response to covid-19 quarantine in Spring 2020, this is a paper describing DE approaches in science education specifically addressing the challenge of meaningfully engage young learners using a mixture of synchronous and asynchronous learning in science.

In an effort to provide young children continued educational opportunities while schools in Cyprus suspended their operation in March 2020, I have developed and taught a program of DE in science for young children that included highly interactive, weekly activities for a series of topics under the theme of "Kitchen Science," following different teaching approaches (investigative-based learning, problem solving and modeling-based learning) Children met synchronously once a week for 60 minutes from April - June 2020, while asynchronous communication mediated through their parents continued throughout the week.

Using a simple, timeline-based Learning Management System (LMS), all communication, instructions, materials, children work submission were organized. These included materials that children used, preparation instructions for each meeting, links for the online meetings, instructions and links for submission of children work after a particular meeting. Synchronous meetings were carried out in the afternoon, during a time at which at least one parent was in position to facilitate the technicalities. During the meetings, children developed (new) habits of working through on-line tasks, including how to take turns for speaking, how to agree or disagree with others and how to ask permission to talk.

For this study, I focus on the investigation of snails (three 60-mintes lessons), their body parts, habits, behaviors and their role in the ecosystem, engaging children in a series of authentic activities. Part of the unit involved the engagement of children in Model-based Learning in science (Louca, 2020). Data consists of field notes prior to and after each synchronous meeting and children-generated work. Following methodological approaches of science classroom discourse (e.g., Gallas, 1995; van Zee et al., 2001; Edwards & Mercer, 1995), I used fieldnotes reflections as a gateway to children's thinking and experience. Data analysis includes the representation of phenomena studied (Louca et al, 2011) and the levels of student participation in the DE activities.

Findings and Discussion

A main challenge during DE during Covid-19 was to increase children learning engagement (e.g., Whittle et al, 2020) especially during the loss of teacher social face-to-face presence (which usually provides guidance), as well as the loss of children social presence (which facilitates formative assessment). Children in the study were actively engaged from home throughout the synchronous meetings as well as the asynchronous tasks.

A factor that contributed to the successful implementation of this unit was engaging children in the collaborative participation in the process of meaning-making (Donaldson, 2020) and knowledge construction.

This was evident by the creation of an on-line community of learners (Itow, 2020) that shared a common purpose for learning and had a mutual contribution to the process of learning. The parents' engagement was also important in this (Whittle et al, 2020), supporting their children with the use of the digital tools, sending their children work/models, and helping children submit their opinions and evaluations of each-other's models.

Despite working from distance, children throughout this unit followed a scientific stance in their work making predictions, collecting observations, confirming ideas, and collaboratively building new knowledge through the development of representations. Two areas of pedagogical ideas may have contributed to this. The first area is related to pedagogical ideas normally used in the face-to-face classroom settings, which were easy to transfer and apply in the DE activities. In order to keep all 20 children engaged during the 60 minutes of the synchronous online tasks, it was important that: (1) The unit included a variety of different tasks, seeking to meaningfully engage children with different learning styles and preferences. This also resulted in a shorter duration of the tasks and more frequent alteration between the activities. (2) The tasks had a highly playful nature. The investigation through an activity designed around a "snail-sprint" is an example of such as task, during which children followed an authentic investigation of snail dietary habits through a playful activity. (3) The tasks included high interaction between children, materials and the instructor. The design of the meetings, activities and task included a number of different interactions, with parents' participation much more active than classroom based face-to-face instruction. In many cases, parents were sitting next to their child participating in the task, or opposite of them (to avoid being present on camera – but their reflection on a window behind their child indicated their presence). This, along with the facilitation on behalf of the parents for the asynchronous tasks created a learning community (Donaldson, 2020; Flynn, 2020) that, in addition to children presence, included the parent presence and interaction with specific characteristics. (4) The tasks followed an authentic inquiry-oriented approach that included both hands-on & minds-on properties (NRC, 2000).

The second area is related to pedagogical ideas that were more productive to use during the DE activities (both synchronous and asynchronous) than in face-to-face activities. (1) Children-friendly digital tools made it easier and more meaningful for children to work, communicate, and build knowledge collaboratively from their homes. (2) Social distancing (quarantine) was used in favor of the learning process. Evaluating peer's work by voting was a necessary task due to the social distancing. When carried out in the regular classroom, this is usually time consuming, and children often vote for their friend's work and not necessarily applying scientific criteria. Social distancing helped to overcome this difficulty. (3) The synchronous and asynchronous communication used, facilitated the formative assessment processes (Whittle et al, 2020). Monitoring children progress through e.g., their work submission and their peer feedback (voting), was a dynamic process that enabled me to appropriately respond to children work, ideas, and reasoning in some cases in better ways than classroom-based teaching.

Worked Examples: Do Learning and Perceived Helpfulness Align?

Avery H. Closser, Hannah Smith, Jenny Yun-Chen Chan, Cindy Trac, Erin Ottmar
aeharrison@wpi.edu, hsmith2@wpi.edu, jchan2@wpi.edu, ctrac@wpi.edu, erottmar@wpi.edu
Worcester Polytechnic Institute

Abstract: Worked examples are effective instructional support but limited research has examined the impacts of different worked example designs in online settings. We measured algebra students' learning gains and perceived helpfulness of worked example designs in an online problem set to identify how *extensive* and *dynamic* worked examples should be in online settings. Students were randomly assigned to view worked examples in: 1) *concise static*, 2) *extended static*, 3) *concise sequential*, 4) *extended sequential*, 5) *dynamic no history*, or 6) *dynamic history* formats. The findings provide recommendations to design worked examples for online settings.

Keywords: worked examples, algebra learning, online learning, perception

Introduction

Worked examples display a step-by-step solution for students to study how to solve a problem. Extensive research has demonstrated the worked example effect showing that studying worked examples is effective for learning beyond problem solving (Sweller, 2006). However, worked examples are typically presented as static images that could be displayed in textbooks. As we look ahead to the future of K-12 education and the increasingly central role of online tools, worked examples should be intentionally designed from theory to support learning in online settings. We reason that there are two primary competing theories: cognitive load theory and perceptual learning.

On the one hand, cognitive load theory posits that studying worked examples frees up students' working memory and cognitive resources for learning, reducing cognitive load (Sweller, 2006). From this perspective, the presentation of worked examples in multimedia should minimize extraneous complexity, avoiding features that would split students' attention, and drawing attention to the problem subgoals (Schwartz et al., 2016). On the other hand, perceptual learning researchers suggest that providing more details in materials to direct students' attention to relevant information can help adapt their perceptual experiences to support high-level cognition. Reasoning about mathematics is inherently perceptual, as ample evidence shows that algebraic learning is influenced by the visual presentation of notation (Goldstone et al., 2017). Therefore, studying worked examples which direct attention to each term, operation, and resulting transformation may increase learning through perceptual processes.

From these theories, we aim to identify how *extensive* (details in derivations) and *dynamic* (static images or looping videos) worked examples should be to optimally support students online. We ask: 1) *Which worked example design is most effective for student learning?*, 2) *Which worked example design do students perceive to be the most helpful?*, and 3) *Do students' learning gains align with their perceived helpfulness of worked example designs?*

Methods

A total of 25 teachers assigned the study to 530 middle-school students from North and Central America as an online problem set to complete individually in class or as homework. Of those students, 259 were assigned an experimental condition and finished the posttest to be included in data analysis. Within the problem set, students first completed an eight-item pretest on algebraic equation solving. Next, students were randomly assigned to a condition, where they completed six problem pairs that each consist of one worked example and one practice problem to solve. Students then completed a posttest mirroring the pretest. Finally, students rated the helpfulness of the worked example design they saw on a 6-point scale and explained their rating.

All of the problem set materials used in the intervention were identical across conditions. We adapted the equations and derivations used for the worked examples from Rittle-Johnson and Star (2007). We created each practice problem to intentionally mirror the structure of its paired worked example. We adapted open-source curricula algebra problems to create the pretest then substituted numbers of similar magnitude to create the posttest.

The study included six experimental conditions. First, the ***concise static*** condition mirrored a commonly used worked example design (Rittle-Johnson & Star, 2007). Students (n=50) viewed each worked example as a static image which displayed the major derivations of each problem. Students in the ***extended static*** condition (n=54) viewed worked examples as static images that showed every step in the derivations. Students in the ***concise sequential*** condition (n=38) viewed looping GIF videos that presented the *concise static* examples line-by-line in 2-3 second intervals to create a step-by-step history of the derivation. Students in the ***extended sequential*** condition (n=42) viewed *extended static* worked examples that were presented in the same way as concise sequential examples. Students in the ***dynamic history*** condition (n=35) viewed looping worked example videos that demonstrated the transformation process through a screen recording. For example, to transform $2(x-3)=8$ to $2x-6=8$, students watched as the 2 was dragged over the parentheses to create the next line, $2x-6=8$, recording the result of the action (Figure 1). Each step of the problem was shown on the following line and a history of the steps taken was displayed sequentially. Last, students in the ***dynamic no history*** condition (n=40) viewed identical transformations to those in the *dynamic history* condition but all occurred on one line of equation without a derivation history.

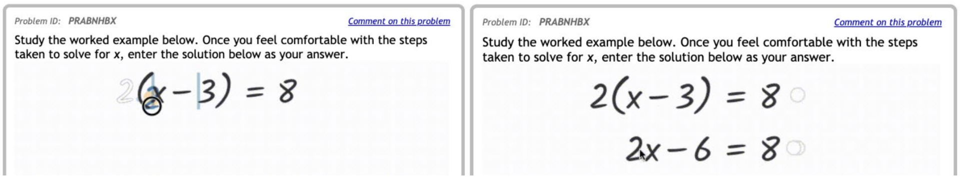

Figure 1. The *dynamic history* design for worked examples shows each transformation.

Results and conclusions

First, a 6(condition) × 2(time: pretest, posttest) repeated measures ANOVA revealed a main effect of time. Students improved from pre- (M= .43, SD=.34) to post-test (M=.48, SD=.37), $F(1,253)=10.02$, p=.002. There was no main effect of condition or an interaction effect. Second, a one-way ANOVA showed no significant differences between conditions on the *perceived helpfulness* of the worked example format (M=3.96, SD=1.43). Third, to detect whether students' learning gains align with how helpful they think the worked example designs are, we qualitatively compared students' learning gains and perceived helpfulness of the designs. The ANOVA findings suggest that, on average, students in all conditions experienced learning gains and perceived the worked examples to be somewhat helpful.

This research provides theoretical and practical contributions by showing that multiple worked example designs are effective for learning in online settings. Similarities across conditions may explain why there were no differences in learning gains; however, we conclude that the worked example effect is robust. Students' perceptions of the worked examples seem broadly aligned with learning outcomes. Moving forward, we will identify themes in free responses (e.g., the videos were too fast or too slow) to guide future research and modifications to the designs.

Design of Multi-Dimensional Science Labs for Future Teachers for Online Learning

Laura Zeller, Stefany Sit, Alister Cunje, Sam Tempel, Ummie Ansari, Mahogany Lawson

Abstract: Providing authentic and engaging science labs for pre-service elementary teachers is important because incomplete science knowledge affects their future teaching. We describe our design project that focused on providing quality physics and earth science labs for pre-elementary education majors within the constraints of online learning. Our design principals draw from the Next Generation Science Standards and the Modeling Instruction methodology (Hestenes, 1996). We present our design process, design principles, and initial findings.

Introduction

Empowering future educators with strong science knowledge is important, and requirements for physical distancing required us to adapt in an engaging and equitable manner. When elementary science teachers have incomplete science knowledge, they compensate in ways that limit student science learning including avoiding hands-on experiences and minimizing subject coverage (Akerson, 2005). As the Covid-19 pandemic forced classes online, we needed to provide engaging and authentic laboratory experiences for future teachers. Authentic lab and field experiences are possible in emergency remote learning (Pennisi, 2020), and university instructors triaged lab experiences during the initial shut down with many different approaches (Fox, Werth, Hoehn, Lewandowski, 2020). Additionally, it is important to design labs to be multi-dimensional, explicitly engaging students with both content and authentic science practices through phenomena, to enhance student learning and help future teachers understand how the Next Generation Science Standards (NGSS) conceptualize science (NGSS Lead States, 2013). Supporting future-teacher learning within the constraints of an online format while maintaining multi-dimensional, collaborative labs requires thoughtful adaptation of lab activities. We engaged in our design work both before and during the semester of our course.

Through our design process and implementation of collaborative labs for future teachers, we have developed design principles that can inform future work and research. We report on our efforts to re-design physics and earth science lab activities for a science content course for pre-elementary education majors including our design principles, our cyclical process for development, examples of resulting labs, and initial findings about strengths and constraints.

Design process

Our lab design process was purposefully iterative, while still fitting within the constraints of designing materials during the semester. Each lab was developed by a course instructor or teaching assistant (TA), using the design principles described below. Design began with the development of learning objectives and guiding questions based on the unit topic. Subsequently, activities, conclusion questions, and reflection prompts were developed for each lab. Once each lab was drafted, the undergraduate peer leaders, who previously took the course, tested the labs with the TAs in a digital environment (Zoom) and provided detailed feedback. Our team of instructors and TAs then reviewed each lab together. The author of each lab then revised it and created supplementary materials such as technology introduction videos and clarifying images. A pre-lab activity was also created to prepare students for the lab. Teaching assistants then implemented labs across three sections of about twenty students each. Afterwards, TAs provided feedback to help other lab sections run smoothly and to make notes for future revisions. Our design cycle benefited student learning through reviewed and revised labs, provided invaluable instructional design experience for our TAs and peer leaders, and created notes for future lab revisions.

Design principles

The goal of our design principles is to guide the creation of multi-dimensional labs that facilitate the students through the learning process of each lab while meaningfully connecting the content and practices to students' future classroom teaching.

Center student talk and engagement in science practices

This design principle is grounded in having students learn science by engaging in authentic, situated learning (Lave & Wenger, 1991). To do this, we included multiple NGSS science practices in each lab, for example asking questions, constructing explanations, and developing models. Inspired by Modeling Instruction (Hestenes, 1996), the participation structures of our labs included individual, small group, and whole group time. TAs presented a phenomenon and discussed how data could be collected, then students worked in small groups and reported out to the whole group to discuss their findings. A majority of the time was spent in small groups to foster student-student talk and place the intellectual work on the students.

Connect to real-world phenomena and students' future classrooms

Connection to the real world helps students contextualize and connect to the science content they are learning. We built our labs around observable phenomena and observations students were likely to have personally experienced. As the course was for future teachers, we wanted to help them think about the science material within the context of their future classrooms. Each lab included reflection prompts that asked students to write about how they saw the material relating to their own lives or being used with their future students.

Include hands-on activities when possible

One major constraint of moving labs from in the classroom to online is the restrictions on lab equipment. For each lab, we tried to incorporate some kind of physical observation or experimentation by providing a lab kit. The lab kits included thing such as: a rock identification kit for geology, a slinky for waves, a mini air puck for motion and forces, and earth and moon balls to create solar system models. The items were specifically selected to be useful in our students' future classrooms as well as in the labs. After the hands-on introductions, online tools were used to engage students in quantitative data analysis in activities that built off the hands-on activities.

Organize shared documents for clarity and to foster online participation

In order to set students up for success and keep them engaged in lab activities, we created a template structure for the lab documents and Google Slides for presentation and group work that we carried throughout the lab. We used icons to indicate participation expectations for each section of the lab and to prompt students to insert screenshots of their work. The Google Slides used for group work allowed the teaching assistants to monitor progress in the digital breakout rooms and help groups as needed. A single grading rubric was developed for all the labs and provided consistency in expectations. We also provided rotating lab roles for the members of each group.

Initial findings

Our preliminary findings are that the online environment exacerbated time constraints and made facilitation of whole group discussion between students more difficult. We found success in engagement within small group work and presenting to the whole group. On our poster, we present examples of student work from the labs and report in more detail about student actions, including how they were able to draw connections between labs and their future teaching. We share our experience, process, and design principles to contribute to the discussions around adapting labs to be online and engaging in real-time course development.

Striving for Adaptivity - Enabling Complex Problem-Solving Processes in a Computer-Based Learning Environment

Striving for Adaptivity - Enabling Complex Problem-Solving Processes in a Computer-Based Learning Environment

Abstract: In multi-phase learning designs with initial problem solving (PS-I) the fit of the subsequent instruction seems crucial for learning. Research shows that individual solution attempts need to be addressed when comparing incorrect and correct solutions in the subsequent instruction phase. A computer-based implementation of a PS-I learning environment offers the possibility of adaptively addressing each individual's solution type but also poses a double challenge: It requires an implementation that allows valid problem-solving processes *and* an accurate diagnosis of problem-solving results. We address these two challenges by investigating two learning environments with different extents of openness.

Keywords: problem solving, learning from errors, computer-based learning environment

Introduction and theoretical background

In multiphase learning scenarios with an initial problem-solving phase followed by an instructional phase (PS-I), those students show the greatest learning effects who compared in the instruction phase the correct solution to a typical student solution that corresponded to their own solution type from the problem-solving phase (Loibl & Leuders, 2019). These findings call for adaptively taking students' solution attempts into account. This adaptivity could be implemented with a computer-based learning environment. The computer-based learning environment should enable valid problem-solving processes. At the same time, the problem solving products must be diagnosable in a computer-based manner to enable automated adaptive instruction. These two challenges influence each other in opposite directions. In their assistance dilemma, Koedinger and Aleven (2007) describe the challenge of balancing giving and withholding information during the learning process (Figure 1). In assessment, there is a validity-reliability dilemma (Figure 2), that is, a discrepancy between the complexity of the assessed knowledge and the diagnosticity (Seifried et al., 2020). In our study, we combine both dilemmas as a trade-off between complexity and accuracy (Figure 3), which needs to be addressed when a learning scenario with an initial problem-solving phase followed by an adaptive instruction phase is to be implemented computer-based.

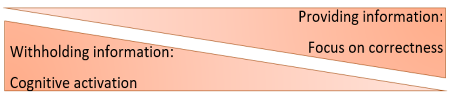

Figure 1. Assistance dilemma

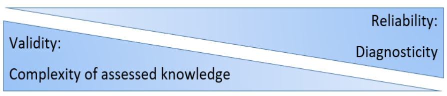

Figure 2. Validity-reliability-dilemma

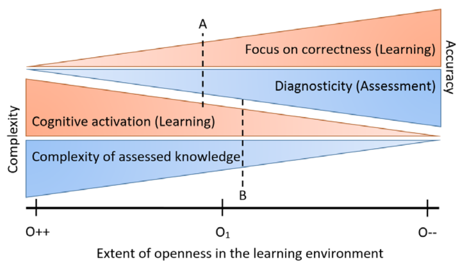

Figure 3. Synthesis of both dilemmas

Schematically, on the left side of the B-mark (higher extent of openness in the learning environment) valid problem-solving processes are possible (complexity), whereas an accurate computer-based diagnosis is difficult. In environments on the right side of the A-mark (lower extent of openness), processes can be diagnosed accurately but these do not represent valid problem solving. A valid problem-solving process and at the same time an accurate diagnosis of the problem-solving result is feasible in the overlap area between A and B, if it exists at all. Our overall ambition is to develop and test a learning environment O_1 in this hypothetical area that allows valid problem-solving processes *and* an accurate diagnosis.

Research question

The analyses of the current paper focus on one challenge of the trade-off, namely the complexity of the problem-solving processes. Our research question is: What influence does the extent of openness of the computer-based learning environment have on the types and frequencies of the solution types?

Methods

63 fifth-graders participated in the present study. The learning unit covered comparing fractions with graphical representations. All students were asked to decide which group win a scoring contest where each kid attempts to score a goal once: a team of 5 girls who scored 3 goals or a team of 10 boys who scored a total of 5 goals.

To investigate this research question, we developed two learning environments O+ and O- in Cinderella. Both variants ask for a graphical solution in the form of fraction bars and a short written answer. The two learning environments differ in their extent of openness: The learning environment O+ (Figure 4) represents the more open learning environment. It is strongly oriented towards the paper-based version (cf. Loibl & Leuders, 2018). Starting from this rather open learning environment O+, we derived the more structured (i.e., less open) learning environment O- (Figure 5) to enable an accurate diagnosis. It can be assumed that the affordances and constraints of the more structured learning environment O- allow a computer-based diagnosis of the conceptual understanding of the learners, but are valid problem-solving processes still feasible despite the pre-structuring?

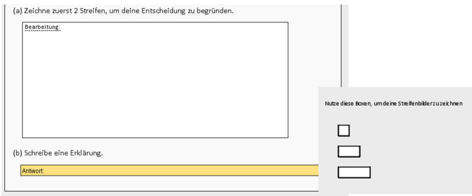

Figure 4. More open learning environment O+.

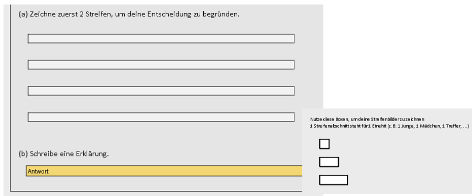

Figure 5. More structured learning environment O-.

The study focused on the problem-solving phase. The students worked in one of the learning environments, followed by a stimulated recall interview. The graphical student solutions and the verbal explanations from the interview were categorized using the coding scheme from Loibl and Leuders (2018).

Findings

Table 1 shows the relative frequencies of the categories in the two learning environments, O+ and O-, and for both levels of diagnosis (graphical and verbal solution). Interrater reliability was very high, $\kappa = .97$.

Table 1: Frequency distribution of categories in the learning environment O+ ($N = 20$) and O- ($N = 43$).

Solution types	Graphical solution		Verbal solution	
	O+	O-	O+	O-
0	25%	37%	15%	23%
1a	55%	37%	50%	42%
1b	10%	7%	15%	9%
1c	10%	7%	5%	14%
2	0%	12%	15%	12%
	χ^2 (4, $N = 63$) = 4.259, $p = 0.372$		χ^2 (4, $N = 63$) = 2.160, $p = 0.706$	

Discussion

The results show that the problem-solving products and their frequencies in the more structured environment O- are similar to the once in the more open environment O+. We interpret this finding as an indicator that valid problem-solving processes are also possible in this more structured learning environment. The next step is to investigate the second part of the trade-off, namely the accuracy. If the graphical solution proves to be a good predictor for conceptual understanding, we can implement an algorithm in the learning environment O- that allows to automatically initiate an adaptive instruction phase after the problems-solving phase.

Integrating Computational Thinking into Elementary Science Online

Abstract: As a result of the COVID-19 pandemic, teachers were forced to consider how their integration of computational thinking (CT) within elementary science would shift during Emergency Remote Teaching (ERT). We present preliminary analysis of interviews with teachers about their experiences and expectations for integrating CT in online teaching and how these expectations mirror and shift integration in-person. We offer principles for designing professional development to support online integration of CT in elementary science.

Introduction

Researchers argue that computational thinking (CT), defined as "the thought process involved in formulating problems such that their solutions can be expressed as computational steps or algorithms to be carried out by a computer" (Lee et al., 2020, p. 1), is a skill every student should learn (Wing, 2006). The value of CT is highlighted in science education, where professional careers are increasingly computational (Weintrop et al., 2016). To introduce CT into the classroom, some professional development (PD) opportunities focus on CT integration within disciplinary contexts, particularly science (Delyser et al., 2018). This type of PD and the focus on CT integration have given CT a stronger foothold within classroom practice.

But this integration has been affected by the COVID-19 pandemic, requiring teachers to reconsider if, how, and when they integrate CT into science lessons. In March 2020, teachers in the U.S. transitioned to Emergency Remote Teaching (ERT; Hodges et al., 2020) and while some schools reopened in-person in the Fall, most adopted either a fully remote or hybrid (part remote, part in-person) model. These transitions required teachers to abruptly transform their teaching, often navigating a redistribution of pedagogical priorities and responsibilities. In this study, we set out to understand how the transition to ERT impacted CT integration and how this transition can inform CT integration in online environments.

Previously, we provided CT PD to pre-service and in-service teachers (Coenraad et al., 2021) with a focus on in-person instruction. In the PD, teachers wrote CT-integrated science lesson plans that included using computational devices for data collection and analysis, using simulations to illustrate scientific phenomena, and extending science learning with programming activities (Cabrera, in preparation). Following up with participants from that PD, we answer the research questions: *How did ERT impact teachers' integration of CT into elementary science?* and *How do teachers expect to integrate CT into elementary science if they continue to teach online?*

Data collection and analysis

We interviewed five elementary teachers (all White women, one Hispanic; 1-15 years of teaching experience) who previously participated in our Spring 2019 PD about their experiences integrating CT during the 2019-2020 school year. All five teachers began the school year teaching in-person but shifted to ERT in March of 2020. We conducted semi-structured audio-recorded interviews during the summer of 2020 focusing on teachers' experiences integrating CT, transitioning to ERT, and their ideas integrating CT in online environments. Interviews lasted 45-80 minutes and were professionally transcribed. The interview transcripts were coded using descriptive coding (Saldaña, 2015) to identify CT integration in-person and online, potential CT-integration online, and barriers to CT integration.

Findings

Although most of the participating teachers had demonstrated the ability to write and enact CT-integrated science lesson plans during the Spring 2019 PD, our interviews showed that no teacher was able to successfully integrate CT into science during ERT. One common barrier to integration was a shift on how and by whom science was taught at schools. As one teacher explained, *"There was only math and reading… then, as online learning went on, they started rolling out science and social studies, but it wasn't taught by the [main] teacher, it was taught by one teacher for the whole school."* Another teacher also shared a shift in priorities and how CT had fallen to the bottom of those: *"just the lack of time that's allocated for Science. I found myself a lot of times having to find ways to integrate science and social studies into math and reading, just to make sure I exposed students to that* *content. So, on top of that, trying to integrate computational thinking is kind of challenging."* Teachers also explained that ERT had also made it difficult to integrate CT by changing the instructional dynamic between teachers and students. A participant described this obstacle as a change in teaching style from *"cooperative learning where the kids learn together…[to] online [where] it is more of a lecture-based type."*

While teachers had difficulty integrating CT during ERT, they were able to identify future means for CT integration online. They specifically identified the potential to integrate programming through online environments, such as Scratch, and computational simulations, such as those available through PhET. One teacher noted both saying, *"What comes to mind is definitely coding, Scratch, things like that, where students can kind of independently explore and work with the technologies…more of those online simulations, things like that."* Teachers identified these technologies *"especially because the students are already on their technology,"* highlighting the online nature of these CT activities and the ability of students to complete them on individual computers without additional resources.

Discussion

From previous work, we know that integrating CT into elementary science is difficult for elementary teachers but moving science instruction online exacerbated the existing barriers they faced. The lack of science instruction time and agency to integrate a new skill like CT became worse during ERT. Advocates of science education should continue to encourage schools and districts to allot significant instructional time to science education. Nevertheless, it is hopeful that teachers recognize ways to integrate CT within the existing context, particularly using simulations and programming. We see pathways that could support teachers to continue the momentum of CT integration as they move forward with ERT and online teaching.

While the teachers who participated in our PD had previously integrated CT through a variety of activities and practices, they saw CT online as limited to easily accessible programming and simulations. However, this conceptualization of CT can be reframed as an opportunity to expand the role of computational tools in science learning—particularly given that districts have now expanded technology access for students learning from home. In our previous work, we observed teachers integrate simulations mostly as a way to visualize a scientific phenomenon, but less often as a tool to test scenarios, answer inquiry questions, and discuss how computational simulations model the real world. Similarly, teachers in our PD often integrated programming only as an extension activity that followed a typical science lesson. Therefore, we suggest that PD designers and teacher educators support instructors in leveraging the affordances of simulations and programming to integrate CT more deeply and making them core practices of science learning. Moreover, it is important that we provide teachers with tools to foster collaborative and active learning online, as they identify that CT is often incompatible with the lecture-based teaching that emerged during ERT.

Show the Flow: Visualizing Students' Problem-Solving Processes in a Dynamic Algebraic Notation Tool

Ji-Eun Lee, Aravind Stalin, Vy Ngo, Katie C. Drzewiecki, Cindy Trac, Erin Ottmar
jlee13@wpi.edu, astalin@wpi.edu, vngo@wpi.edu, kcdrzewiecki@wpi.edu, ctrac@wpi.edu, erottmar@wpi.edu
Worcester Polytechnic Institute

Abstract: We apply an advanced data visualization technique, *Sankey diagram*, to explore how middle-school students ($N = 343$) solved problems in a game-based algebraic notation tool. The results indicate that there is a large variation in the types of students' strategies to solve the problems, with some approaches being more efficient than others. The findings suggest that Sankey diagrams can be used both in research and practice to unpack our understanding of variability in mathematical problem-solving.

Keywords: math learning, problem-solving strategies, data visualization, Sankey diagram

Introduction

Teachers' knowledge of their students' learning is one of the important factors contributing to classroom practices, and ultimately, what students learn in mathematics (Asquith et al., 2007). However, teachers often have difficulties in monitoring students' learning progress or identifying their misconceptions. In response to these issues, advances in data analytics and visualizations have enabled teachers and researchers to identify complex data on student learning in an easier and faster way. However, there has been little research that has employed advanced data visualization techniques on students' mathematical learning processes (Vieira et al., 2018). Over the past several years, our team has designed and developed a dynamic algebraic notation tool, *Graspable Math* (GM), which helps develop students' conceptual and procedural learning in algebra. The tool allows students to dynamically manipulate and transform numbers and mathematical expressions using various touch or mouse-based gesture-actions. Using the data collected in GM, students' problem-solving processes can be represented as a series of time-based steps that form the mathematical derivation as they transform mathematical expressions and equations. Thus, the purposes of this study are to 1) present visualizations of students' algebraic problem-solving processes in GM using an advanced and novel data visualization technique, called *Sankey diagram*, and 2) investigate how we can use these visualizations to provide meaningful and comprehensive information to researchers and teachers.

Methods

Our sample ($N = 343$) was drawn from a randomized controlled study conducted in 2019. Of the 343 students (54% male, 43% female, 3% not reported), most students (96%) were in sixth grade, and the remaining students (4%) were in seventh grade. *From Here to There!* (FH2T, https://graspablemath.com/projects/fh2t), is a gamified version of the GM that was developed to help students' algebra learning. It allows students to dynamically manipulate and transform numbers/mathematical expressions using various gestures. The problems in the game consist of two mathematically equivalent mathematical expressions, a start state and a goal state. Students must transform the starting expression into the target goal state using algebraically permissible actions. Among the 252 problems that cover a variety of mathematical concepts, this study focuses on two multiplication problems.

Results

Figure 1 presents the students' problem-solving processes for the square numbers problem (turning "9×4" into "3×6×2"). Each node in the diagram represents a different mathematical expression made by students, and the thickness of each path represents the number of students who made that expression. Colors in the diagram represent the productivity of students' first steps (blue: productive, red: non-productive). As shown in Figure 1, more than half of the students made productive first steps for this problem (e.g., 3×3×4, 9×2×2), and most of them solved the problem with the fewest possible steps to reach the goal state. On the contrary, the students who made non-productive first steps (e.g., 36, (3+6)×4) did not solve the problem in the most efficient way. Thus, noticing the underlying structure of the problem equation and how to transform it played a critical role in students' subsequent transformations as well as their overall efficiency of algebraic problem-solving.

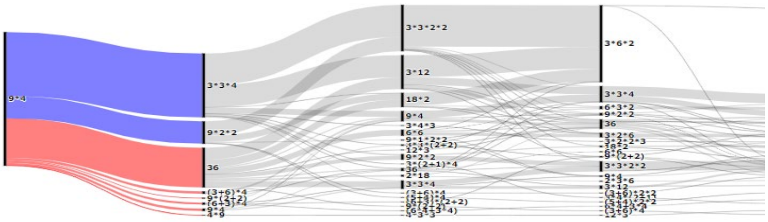

Figure 1. Section of the Sankey diagram showing productivity of initial solution strategies for the square numbers problem (for full image: http://tiny.cc/pd51tz)

Figure 2 presents the students' problem-solving processes for the non-square numbers problem (turning "6×10" into "2×15×2"). Most students who made the numbers in the goal state (e.g., 2) or the factors (e.g., 3, 5) of the numbers in the goal state on their first steps solved the problem in the most efficient way. However, the students who did not attend to the structure of the problem and simply combined two numbers failed to solve the problem in the most efficient way. Specifically, many of the students who made 60 on their first step did not solve the problem in the most efficient way, indicating that factoring 60 into small numbers was an obstacle point to the students. Thus, as demonstrated by the Sankey diagram, students' first mathematical transformation played a significant role in students' subsequent and overall efficiency of problem-solving.

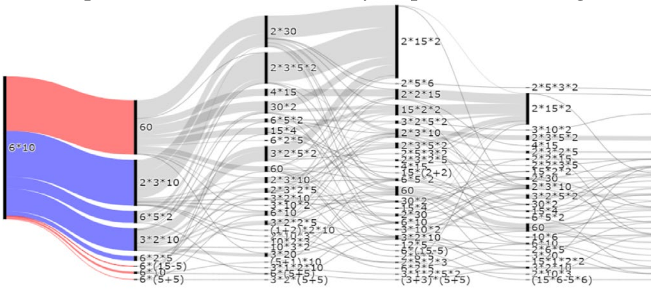

Figure 2. Section of the Sankey diagram showing students' problem-solving processes for the non-square numbers problem (for full image: http://tiny.cc/wd51tz)

Discussion

This work presents a new way to visualize students' problem-solving processes in a dynamic algebraic notation tool. The results showed that Sankey diagrams could provide a lot of information to help teachers and researchers efficiently understand students' algebraic problem-solving processes. They presented the variability of problem-solving processes, the most common pathways used, the obstacle points of problem-solving, and the efficiency of different solution strategies. In particular, the diagrams revealed that noticing the underlying structure of the problem equation and how to transform it on their first step played a critical role in students' subsequent transformations as well as their overall efficiency of problem-solving (Stephens et al., 2013). Visualizing students' problem-solving processes for a given mathematical task would help teachers and researchers perceive students' individual differences and their mathematical thinking processes. This work has clear implications for practice as students' strategies are often invisible to teachers. In combination with the GM, teachers could use these visualizations in several ways to inform their instruction.

A Multimodal Discourse Analysis of Textbooks: A Case Study of *Oxford Junior Middle School English (Shanghai Edition)*

Meng Li, East China Normal University, 15651721502@163.com

Abstract: This research chooses *Oxford Junior Middle School English (Shanghai Edition)* for a multimodal discourse analysis. Applying Kress and van Leeuwen's Visual Grammar and Royce's Ideational Intersemiotic Complementarity as the theoretical framework, the research investigates how visual images construct three meta-functional meanings and explores the relations between texts and images. It is found that the frequency of using repetition, synonymy and hyponymy is the highest. Such design facilitates students to understand textbooks more comprehensively.

Background

With the fast development of multimedia and the arrival of the information age, multimodal means of communication are flourishing and influencing the traditional way of thinking. The expression of information has changed from relying on a single mode to combining multiple channels. In the field of education, textbooks convey information to readers with the help of multiple modes. Texts, illustrations, tables, tapes, videos, PPT and so on all together help teachers and students better understand textbooks. They are an important medium that directly connects teachers, students and knowledge.

However, second language learners usually pay more attention to vocabulary and grammar which are embodied in the texts than other modes. In China, students who learn English often recite words and sentences, thinking little of pictures. After all, examinations are usually presented in the form of texts. In fact, this kind of study is not beneficial to develop multiliteracies of learners that are so important in such a modern society filled with multiple modes. Therefore, it is necessary for researchers to explore how multiple modes in textbooks convey knowledge together. By investigating how visual images construct three meta-functional meanings and exploring the relations between texts and images, this research is aimed at assisting both teachers and students. Teachers can further understand multimodal discourse in textbooks by expanding their focus on texts to both texts and other modes. Moreover, when teachers pay attention to those modes, students who are under the guidance of teachers learn to attach importance to them, helping to improve their development of multiliteracies and adapt to modern society better.

Research design

Research object

This research chooses the reading part of *Oxford Junior Middle School English (Shanghai Edition)* to do a multimodal discourse analysis. Six books are analyzed, including 7A published in 2008, 7B in 2009, 8A in 2009, 8B in 2010, 9A in 2010 and 9B in 2011. There are 52 articles and 135 pictures in total (see Table 1).

Table 1: A table for articles and pictures in textbooks

	7A	7B	8A	8B	9A	9B	Total
Articles	12	13	7	8	7	5	52
Pictures	45	35	18	13	12	12	135

Research method

This research analyzes textbooks from the perspective of multimodal discourse analysis, which focuses on multiple semiotic resources like texts and images. The main research method is case analysis. There are two reasons to choose English textbooks used in Shanghai as a case. Shanghai is a pioneer in curriculum reform and Shanghai students performed very well in PISA, and in English learning as well. It is helpful to demystify educational ideas from the perspective of analyzing textbooks. There is no denying the fact that this series of textbooks contribute to some extent. Therefore, it is necessary to analyze this series so as to better understand textbooks and get some enlightenment.

Theoretical framework
Based on Visual Grammar's three dimensions, namely representational, interactive and compositional meaning proposed in Kress and van Leeuwen's (2006) book, *Reading Images, the Grammar of Visual Design*, this research classifies and analyzes pictures in the textbooks to interpret the meaning and function of images. It also explores relations between images and texts based on Royce's (2007) Ideational Intersemiotic Complementarity theory. By combining such two theories, this study analyzes the multimodal characteristics of textbooks, provides new theoretical perspectives for textbook analysis and interpretation, and promotes English teaching and learning.

Coding
This research classifies each picture and relations between pictures and texts according to the definition of theories and then records results in the Excel. For example, according to Visual Grammar, the action process has vectors formed by oblique lines which are composed of represented participants' tools or limbs. Figure 1 shows that three cleaners are cleaning streets (see Figure 1). The represented participants are cleaners. The two obvious vectors are the lines formed by cleaners' action, holding the broom and the water pipe. This picture depicts the action that the text embodies, that is, the cleaners sweep the streets and collect rubbish. Therefore, it belongs to action process.

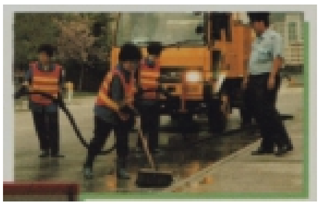

Figure 1. The action process.

Findings
First of all, as to the representational meaning, the total amount of narrative process exceeds the totality of conceptual process to a prominent extent for the reason that narrative process makes students less demanding to join in the reading through vectors of actions and eyes. In regard to the interactive meaning, the main relationship in the contact presented in pictures is "offer", because the role of textbooks is to provide readers with information, not to ask readers for something. In addition, the frontal angle and the head-up angle are in the majority, more than half of the total number. With respect to the compositional meaning, the information on the right section which offers new information to arouse readers' interest in reading contributes most. Apart from that, it is found that pictures with lines are decreasing with junior school students' age increasing because when they grow older and own a higher cognitive level, pictures without lines are not likely to distract them.

Secondly, in the aspect of figuring out the relations between texts and images in making the meaning coherent based on the Ideational Intersemiotic Complementarity, the frequency of using repetition, synonymy and hyponymy is the highest because an image which conveys the same denotation as the text expresses can facilitate students to understand textbooks more thoroughly.

Conclusion and discussion
The findings show that every picture constructs its own meta-functional meaning and most pictures have a good consistency with texts, except some pictures which mismatch texts, causing learners' misunderstanding. It is better for textbook writers to be more careful when they choose pictures. The significance of this research is that it not only expands the application scope of two theories mentioned above, but also provides a new perspective and some enlightenment for understanding textbooks. To better understand and use them, it is necessary for teachers and students to pay attention to those multiple modes first instead of focusing on texts only. In addition, teachers can invite students together to analyze the function of different modes and explore how they cooperate with each other to successfully convey meaning. The function may be interpreted from different perspectives. It is the awareness to analyze and interpret that matters a lot. This research's perspective is just an example and there is broader space to explore for educators and learners who have a creative thinking.

Supporting Children's Spatial Representation Practices through Playful and Embodied Experiences

Megan Wongkamalasai, University of Georgia, megan.wongkamalasai@uga.edu
Christine Lee, University of California, Los Angeles, clee@labschool.ucla.edu

Abstract: This poster examines how embodied and playful STEM learning supports young children's visualization and representation of space. We present two case studies where participants engaged in playful experiences with movement in space and later used these dynamic experiences to create and interpret spatial representations. As part of the conference theme, we aim to examine and reflect on how these playful and embodied experiences can extend current approaches to spatial reasoning and visualization in STEM education.

Theoretical framework

Generating and interpreting spatial representations play critical roles across STEM domains (National Research Council, 2006). However, current early STEM instruction largely neglects cultivating children's considerations of what about space is worth representing and how to go about symbolizing or inscribing this spatial content. We draw and build from research on the embodied nature of reasoning and creating spatial representations to examine how childhood activities (like object play and dramatic role play) can support disciplinary spatial understanding in different ways (Keifert, et al., 2020; Ng & Sinclair 2015; Thom & McGarvey, 2015). Our current aim is to further understand how forms of embodied learning rooted in playful experiences moving in space can support children's representations of space in other mediums, including collage making, notation, and pattern design. Specifically, this paper addresses the following question: How do different playful embodied learning experiences support children's development of spatial representation practices?

Methods

To address our research question, we present two cases of early STEM learning in 1st and 2nd grade classrooms that examine how children's playful encounters with movement can promote embodied learning of dynamic spatial relations and serve as resources for representing these relations in 2-D, static representations. Although both cases focus on playful movement and spatial representations, we also selected these cases because of their differences. Case 1 presents an analysis of children playing with an object while case 2 presents an analysis of children engaged in dramatic role play. Case 1 looks at small scale, discrete movements in the context of pattern design; Case 2 looks at large scale, multi-party movements in the context of collage making. Our current and developing analysis looks to understand how these scales of movement and space relate to children's emergent representational practices.

Findings

Case 1: Movement in space represented in pattern making

This case took place in a 1st grade (ages 6-7) classroom (n = 27) in a public elementary school in the U.S. Data comes from a larger project aimed at connecting movement, design, and spatial mathematics in grades K-5. Here, our case study focuses on a whole class discussion from day 4 of a 5-day instructional sequence on the use of geometric motions (slides, flips, and turns) to create and analyze symmetrical frieze (1-dimensional) patterns. Analysis of this case focuses on how children interpreted frieze patterns using the motions they previously explored in their playful encounters with a fictional 2-D dinosaur, Mr. Dino. These initial playful experiences of moving Mr. Dino encouraged children to create categories of similar motions by distinguishing between the direction of movement (e.g., slide left or right). Teacher then helped further these distinctions in motions by introducing points of rotation and lines of reflection to further extend children's conceptions of ways to move Mr. Dino.

In order to communicate distinctions of movements in space that children experienced while playing with Mr. Dino, the class invented a notational system that included ways to symbolize direction and center of motion. After children played with different ways of moving Mr. Dino, they then analyzed and created frieze patterns by moving and tracing asymmetric figures. To preserve how children made their patterns or how they visualized others' patterns, children used the classroom invented notational system to create a record of their enacted or imagined movements. These records allowed the class to compare the movements used by pattern makers and the different ways of visualizing these patterns. In sum, children's initial playful explorations of motions and the symbolization of these motions supported children in visualizing static 2-D patterns through a lens of dynamic transformations— a critical aspect of mathematical visualization.

Case 2: Movement in space represented in children's collage making

Our second case is from a larger study (n=26) that took place in a mixed-age dual language classroom (English and Spanish) of 1st and 2nd grade students at a progressive elementary school in the U.S. (ages 6-8). The case study follows four children learning both science and math concepts by role-playing as various marine animals, algae, and plants living together in a kelp forest ecosystem (i.e. sea otters, sea urchins, kelp, fish, plankton). With the guidance of their teacher, children moved and organized themselves in ways that represented how these marine creatures would interact with one another in the ocean. For example, children role-playing as smaller creatures (fish or sea urchins) would often "swim away" from children playing as predators and rely on children who played as kelp as sources of shelter or food. Thus, while the movements individual children performed in space (e.g. swimming away, hiding, etc.) were determined by which marine creatures they were assigned, the resulting emergent and collective movement of the class embodied and represented the interdependent relationships in the kelp forest ecosystem.

Following each role-play activity, children documented, represented, and shared what they learned about the kelp forest ecosystem in group collage making activities. Over time, two of the most salient changes of the collage making activities were how the playful experiences of movement in space were documented in ways that (1) showed how each piece of the ecosystem moves within the kelp forest and (2) showed the relational movement within a living, moving, and dynamic ecosystem. We also saw children connect the movement of each sea creature to others by using arrows—the arrows represent the larger food web where specific characters rely on others for survival. In sum, children's role-playing experience of embodying the ecosystem supported their visualization and illustration of the kelp forest that communicated the moving, interconnected, and relational thinking that is central to STEM practices.

Conclusions

Findings from our two cases demonstrate how playful embodied experiences are activities where children utilize movement in space to make sense of disciplinary spatial relationships. Children's embodied and playful experiences are then further reflected on, and ultimately serve as resources in children's spatial representational practices as they work to communicate previously embodied spatial relations in new mediums (e.g. notational systems, patterns, and collages). Findings have the potential to contribute to the growing research on developing spatial understanding in early elementary years by presenting two cases of learning that place playful movement at the center of early disciplinary spatial learning and representational practices. Additionally, although pattern and collage making are not often found in STEM classrooms, these artistic representational practices served as productive entry points for children to consider how dynamic spatial relations, first experienced in playful embodied experiences, can be inscribed in static representations. Thus, these findings also highlight the potential role that playful movement and artistic representations can have in developing children's spatial reasoning within STEM learning.

Supporting Youth Environmental Interest and Identity Development through Program Infrastructures Connecting People and Place

Marijke Hecht, Penn State Greater Allegheny, marijke@psu.edu

Abstract: This case study of an informal science program in an urban park explores adolescent environmental interest and identity development. Using participant observations, interviews, and artifact analysis, I identified three program infrastructures that rely on relational processes between youth, educators, and more-than-human nature to support this development. They are: 1) encouraging physical interaction between human/more-than-human nature; 2) providing youth opportunities to be caretakers of land and waters; 3) exposing youth to visions of their future selves.

Introduction

Science interest and identity are important components for civic engagement (Rudolph & Horibe, 2016). Civic science identity that builds on knowledge of and direct experience with the natural world is essential given the global climate crisis and local environmental issues, such as water quality degradation (Tewksbury et al., 2014). Informal science programs can play an important role in supporting youth environmental interest development (Carlone et al., 2015). However, informal programs often only spark interest (Hecht, Knutson, & Crowley, 2019), even though this is just a first step in developing persistent individual interest (Hidi & Renninger, 2006).

In this program case study, I examine program elements designed to support the deepening of environmental interest for a group of adolescent learners as they transition from initial interest to individual interest and identity development. This case study is of an urban environmental education program designed for teens who had expressed initial interest in the environment and wanted to learn more. The program drew on naturalist practices to deepen youth interest and skills. The park organization that led the program paid youth a stipend and provided youth gear for outdoor activities (e.g., work boots). The stipend and gear facilitated equitable access to program participation but did not alter the informal tenor of the program activities. Therefore, I characterize this as an informal science program because of the emphasis on choice based, interest-driven learning and participation in scientific practices in the informal learning setting of a park (Sacco, Falk, & Bell, 2014).

This project was part of a research-practice partnership which aimed to support the needs of the entire project team including university-based researchers and environmental educators with the park organization. We maintained structured opportunities for collaboration, including six months of planning meetings before data collection began in order to understand practitioner problems of practice, co-develop research questions and program activities to support both learning objectives and data collection needs, and analyze data during meetings that extended more than six months after data collection was completed. This consistent process allowed our team to authentically co-construct the unfolding knowledge described here. Our research questions were:

- What program infrastructures facilitate relational processes between youth, educators, and more-than-human nature?
- How do these program infrastructures support youth development of environmental interest and identity?

Methods

After the co-design of research questions and program activities with practitioner partners, I conducted observations, interviews, and artifact analysis as a participant observer in the program. The data include 89 hours of observations (i.e., handwritten jottings expanded into typed fieldnotes); artifacts from program activities (e.g., youth field journals); and audio recorded and transcribed interviews of youth and educators (n=16), youth large group discussions (n=3), and educator debriefing sessions (n=10). To center the materiality of the park, each interviewee selected an outdoor walking route or place to sit for our interview. This was inspired by work that explores the significance of walking for embodied learning in informal learning settings (Marin & Bang, 2018).

My observational practice focused on robust episodes of interest expressed through interactions between educators, youth, and more-than-human nature. Episodes lasted from 15 minutes to an hour or more and were defined as observable youth expression of environmental interest such as auditory cues (e.g., question asking, concentrated silence) or physical actions (e.g., leaning in, facial expressions). Episodes included human-human interactions (e.g., youth asking questions about environmental phenomena), human-tool interaction (e.g., use of field guides), and human-more-than-human interactions (e.g., tasting a wild edible plant). Data analysis included thematic coding of observational notes, followed by collaborative code review and modification with practitioner partners. I then created structured case summaries that triangulated observational data with other data sources.

Findings

Using these structured case summaries, I worked with practitioner partners to identify key program infrastructures that contributed to deepening environmental interest for participating youth. These were: 1) encouraging physical interaction between humans and more-than-human nature; 2) providing meaningful opportunities for youth to be caretakers of land and waters; and 3) exposing youth to possible visions of their future selves. These infrastructures resulted from deliberate educator design choices to support environmental identity formation and reflect the park organization's philosophy that nurturing a human community is an essential part of coming into community with more-than-human nature and that direct contact with the more-than-human natural world should be driven by curiosity and must respect people's prior experiences, which may include fear. I frame these as *infrastructures* to indicate their structural nature (Penuel, Lee, & Bevan, 2014).

All three program infrastructures were deeply entwined. For example, one of the youth participants, Charlotte, engaged in physical contact with more-than-human nature primarily through watershed stewardship projects, such as building a rain garden, as well as stream surveys, which included finding, handling, and identifying macroinvertebrates. These activities were facilitated by program educators as well as guest environmental professionals, such as a restoration ecologist. Her experiences involved direct physical contact with the more-than-human natural world through stewardship and inquiry activities, as well as examples of possible careers. These helped Charlotte grow her preliminary interest into a deeper individual interest that included a vision of her future as an environmental professional.

In her interview, Charlotte articulated how inquiry and stewardship activities helped her think about her future self, describing her fascination with how the park organization was taking a regional water quality problem and addressing it in a small watershed. She was especially interested in the problem-solving aspects of watershed stewardship, which married her interests in engineering and outdoor work. On the last day of the program when she was asked to reflect on highs and lows from the summer, Charlotte brought up her new understanding of environmental work as a potential career, expressing the start of a potentially long-term environmental identity:

> I think just like knowing that working with the environment is a career option to explore cause before I was just like oh, science, something with science, and then I'm thinking I like definitely wanna do something with the environment, yeah, be out in nature.

Conclusion

This work explores how an informal science education program utilized three program infrastructures to support environmental interest and identity development by emphasizing relational processes between educators, youth, and more-than-human nature. While these findings are limited by the fact that this is a case study focused on just one program, the findings contribute to conceptualizations of effective program design for environmental interest and identity development. The park organization and other informal science programs might consider using these infrastructures to help shape future program design that supports environmental interest and identity development.

Exploring Prompted Self-Explanation in the Context of Second Language Acquisition in Vocational Settings

Sai Raj Reddy, Vivek Seshadri
t-sairre@microsoft.com, visesha@microsoft.com
Microsoft Research India

Abstract: In the Global South, English-language fluency is strongly associated with earnings. This in particular impacts young adults in low-income settings looking to start work in urban areas without past access to high-quality English language education. Evaluating English efficiency in low-resource settings is challenging due to the complexity of the popular assessment tools. In this work, we explore prompted self-explanation as a potential tool for assessing student efficacy in English grammar concepts with students undergoing a vocational training program. Using in-depth analysis of video recordings of students explaining concepts in English as a Second Language (ESL), we find that self-explanation (1) correlates with overall ESL assessment scores, and thus can be a scalable assessment tool and (2) assists learners identify and correct errors, potentially useful as a learning tool.

Problem

Throughout much of the world, especially in parts of the Global South, English-language proficiency is seen as an aspiration and opportunity to achieve higher socio-economic status. It is often considered as linguistic currency and in fact, previous studies have shown that English fluency is strongly linked to earnings (Azam et al. (2013)). In India, there is linguistic diversity in terms of number of languages spoken and there is an ambition among the youth to learn English. Young adults from underprivileged communities face learning poverty and miss out on quality English education. The increase in gig economy work available in urban centres (e.g., delivery agents, call centres) has been a further push for English language acquisition, since most of these jobs require basic ability to navigate written English and conduct telephone conversations.

Access to English education in marginalized communities is mainly via vocational education. There are numerous training centres that train adults for various skill-specific education while also training them in English. To measure the English proficiency, summative assessments are often used that involve a standard comparison. CEFR descriptors (Common European Framework of Reference for Languages) is a popular framework to create an assessment tool for measuring English proficiency. However, the insights from CEFR tools might not be helpful for the learner / trainer to capture the learning gaps. Also, non-native English speakers tend to learn English via combinations of vernacular language cues.

Self-explanation as an assessment tool

This problem motivated us to try out self-explanation due to its simplicity in evaluation of learner's mental model whose learning is based on culturally relevant information (especially for non-native English speakers). Self-explanation is an engaging learning method that has demonstrated its usefulness in other fields, consisting of students illustrating knowledge of learning materials by themselves. Prior works (Chi et al. (1989, 1994, 1996); Bielaczyc et al. (1995)) have explored the effects of self-explanation on learning across various domains like computer programming, math, and science. However, the participants in all these prior studies are mainly students from conventional schools and universities. More importantly, in majority of the studies, the language of self-explanation itself is in English. In this work, we explore the use of self-explanation by students who have l imited educational background to uncover some insights on learning of English as a Second Language (ESL).

Methodology

For this study, we partnered with a non-profit organisation that offers short-term vocational skill-development programs to youth from low-income, underprivileged communities. In our study, we worked with 16 students undergoing training to become *delivery service agents*. We asked each of the 16 students to self-explain one of the concepts in English as a Second Language (ESL). All participants were educated at most up to grade 12. As women are typically not part of the delivery agent workforce, all our participants were male.

We conducted the study with one student at a time at the training premises. We explained the project to the student and the procedure for the study. We asked the student to pick a topic that they would like to explain. The student was provided with access to a whiteboard on which they can write as they are explaining the concept. A laptop was placed facing the student which records the self-explanation session of each student. Once the student is ready with a topic, the researcher started the recording and left the premises. If a student had difficulty choosing a topic, we asked them to self-explain the *English Alphabet*.

At the end of the study, we transcribed and analysed the videos from all the students to extract multiple metrics, such as number of self-explanation inferences (Chi et. Al, 1994), and time spent on different activities like explaining the concept, providing examples, and writing down information. We use the number of self-explanation inferences as a metric to determine a student's ability to self-explain a concept.

Findings

Our analysis results in multiple conclusions. First, *Figure 1* shows the breakdown of time spent on different activities and the number of self-explanation inferences, for each student. As can be seen, while almost all students used the whiteboard to write down information, students with lower self-explanation ability (left half of the graph) spend a larger fraction of their time in writing down rote information on the white board. On the other hand, students with higher self-explanation ability spend a significant amount of time on not only explaining the concept, but also providing relevant examples. Second, we find a strong correlation (0.72) between the ability of a student to self-explain and their overall ESL abilities, showing that ability to self-explain can be an indicator of their English fluency. Third, we find that the overall time spent speaking (explain concepts and example) correlates strongly (0.81) with the ability to self-explain. Combined with the previous finding, we believe self-explanation can be a scalable tool to automatically evaluate a student's ESL abilities and understanding of specific concepts. Finally, in certain instances, students self-corrected their mental models after they identified errors in some of their previous explanations.

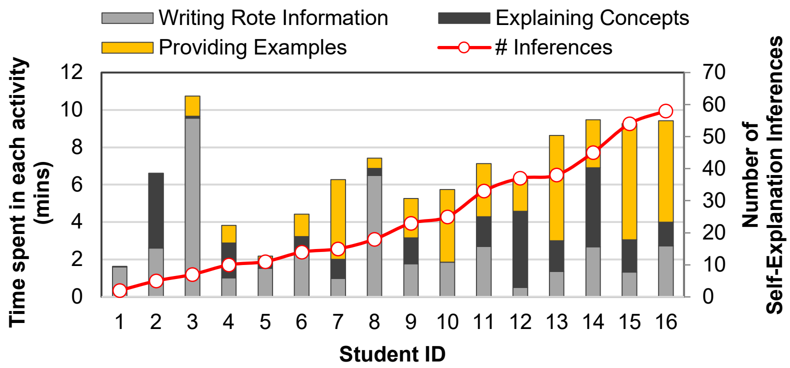

Figure 1. Time spent on different activities and number of self-explanation inferences for each student.

Discussion and conclusion

Compared to other studies, our research concentrates on underprivileged youth. However, our findings are consistent with previous work in certain aspects, such as the number of inferences produced and its correlation with the grades of students. Our analysis shows that high-explainers spend more time on examples, and their ESL scores are strongly correlated with the number of inferences they generate.

One of the drawbacks of the design of learning materials or technologies is that potential learners might not be able to express their learning difficulties and, this technique may allow us to gain more insights into the student's approaches to learning. The self-explanation method might be useful when summative assessments do not give us enough accurate reflection of learning. It can reveal insights regardless of the student's experience and skills. Our findings make a good case to show that self-explanation can be explored as an evaluation methodology.

Beyond Supervision: Human / Machine Distributed Learning in Learning Sciences Research

Marcus Kubsch, IPN – Leibniz Institute for Science and Mathematics Education, kubsch@leibniz-ipn.de
Joshua M. Rosenberg, University of Tennessee, Knoxville, jmrosenberg@utk.edu
Christina Krist, University of Illinois at Urbana-Champaign, ckrist@illinois.edu

Abstract: Machine Learning (ML) is at the core of a new set of methodologies that are currently taking the world by storm and that have a great potential to advance research in the learning sciences. However, research has mostly focused on applying top-down methodologies effectively aiming at replacing humans. However, this hinges on the assumption of scale effects and transferability of trained ML models across populations – assumptions that may not hold in learning sciences research. We discuss the potentials and pitfalls of supervised and unsupervised ML for the learning sciences and argue that the greatest benefits from the use of ML lies in supporting humans so that researchers can tap into new data sources and enhance the validity of their inferences.

What learning machines can and cannot do

Machine Learning (ML) has greatly improved during the last decade and is commonplace in contemporary life. How can this potential be harnessed for the learning sciences? To answer this question, we draw on how Breiman (2001) conceptualized the affordances of ML. Figure 1 shows that ML comes to results about the relationship between two variables x and y by trying to find an algorithmic function *f*(x) that predicts y. It does not make any assumption about the actual process that relates the variables. On one side, the resulting algorithmic functions *f*(x) have unprecedented accuracy in terms of predicting y, on the other hand, they become increasingly uninterpretable with growing accuracy. In consequence, it is hard if not impossible to relate results from ML back to theory as ML does not yield something like regression coefficients. Another consequence of black-boxing the process model is that results from ML—at least current methods—cannot identify causation (Pearl & Mackenzie, 2018).

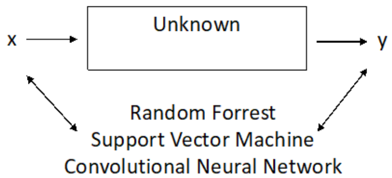

Figure 1. How ML determines the relationship between variables x and y (adapted from Breiman [2001]).

But how does ML identify the algorithmic functions *f*(x)? There are two main approaches. Unsupervised learning is used to learn structural relationships in datasets and does not require the data to have pre-existing labels. Supervised learning tries to learn a function that maps elements onto each other given a set of examples.

What supervised and unsupervised learning have in common, despite the sometimes vocal contrary claims, is that they are not bias-free (O'Neil, 2016). In unsupervised learning, bias can be introduced through the dataset in which the machine learns a structure. When researchers put together a data set, they make decisions, e.g., what to include in the data set, etc. These decisions can reflect biases. For example, if researchers try to learn the social structure of a class based on students' interactions within a chat group, bias will be introduced if students with only limited Internet access participate. Bias can also be introduced through labeled data in supervised learning. If the selected elements between which the machine is supposed to learn a function, e.g., if examples for good explanations follow a certain structure, this will result in bias against idiosyncratic but still good explanations.

In sum, ML can identify structure in unlabeled data (unsupervised learning) and identify mappings between variables based on examples (supervised learning). In both cases, ML essentially trades accuracy for interpretability as compared to classical statistics (Breiman, 2001). In consequence, results can hardly be mapped to theory. Further, results of ML are in fact susceptible to the bias inherent to the collection of data (O'Neil, 2016).

How ML is used at present in the learning sciences

Recently, meta-analyses found that the primary focus of using ML in (science) education so far has been using supervised ML to automatize the coding of students' work. Proponents of this approach often argue that automated coding allows better assessment as it purportedly allows to score open-ended and thus more valid assessments more reliably than human scorers can. This would allow to economically scale many research efforts, allowing for higher statistical power and more precise statistical estimates. In addition, automated coding is a precondition for individualized instruction with real-time feedback, which could be used to assist teachers. However, there are two fundamental problems with this argument regarding the economic advantages and the absence of bias in ML.

Replacing human coders with supervised ML only becomes more economic when sample sizes increase drastically. For the machine to learn how to code, it needs a certain number of examples: answers that have been determined by humans. If the amount of data left after what is coded for training does not massively exceed the amount needed for training, ML is not economically viable (Nehm & Haertig, 2012). Further, when the students that answer the questions change, the initially trained algorithm may produce biased results. Addressing this issue is a very active area of research in computer science but far from being solved (Pearl & Mackenzie, 2018).

The coding of students' answers needs to be valid and reliable. Quality measures of supervised ML however only consider reliability. For validity, examples from human coders are taken as the gold standard although it is well known that this assumption is problematic (Nelson, 2020). Further, a dire consequence may be that structural inequality manifest in human biases is perpetuated by machines ad infinitum (O'Neil, 2016).

In summary, ML is currently mostly used in automated scoring applications in the form of supervised ML. While this certainly has the potential to improve teaching and learning (freeing up teachers' resources, allowing real-time feedback), fundamental issues regarding the ethics and mechanics of ML are still need to be solved (O'Neil, 2016). If supervised ML cannot replace humans yet (and may never be able to), what, then, could be viable applications of ML in the learning sciences?

Human / Machine distributed learning

The learning sciences aim to understand learning and then apply that understanding to improve teaching and learning. We argue that integrating human and ML can help learning sciences research in two ways. First, ML can help the validity and reliability of the qualitative research that develops theory. Nelson (2020) has developed a framework that incorporates unsupervised ML into theory-generating research that aims at making such research more reliable and valid through a three-step process. The first step leverages the power of computers in pattern detection in large datasets. The second step leverages the interpretative power of humans to add quality and depth to the quantity and breadth of the first step. The final third step uses computers to test the reliability and generalizability of the human refined pattern detection and interpretation from the second step. Second, ML can help to explore and exploit new data sources from digital learning environments. When students answer tasks on a computer, this gives researchers additional data beyond the answer itself. This data ranges from logs of keystrokes to biomarkers from wearables. For humans, such data is usually uninterpretable unless specific task affordances can be mapped onto specific patterns in data. Computers, however, can detect patterns in such data, inviting the use of unsupervised ML techniques. Further, especially in the case of voice data, powerful computer models exist to extract valuable information relevant to the understanding of students' learning.

Conclusion

Work in the learning sciences using ML currently focuses on automating coding processes. While impressive advances have been made in this area, unresolved issues regarding the ethics and mechanics of ML make it questionable whether valid and reliable automated coding is viable in the foreseeable future given the goals and values of the learning sciences. We argue for the value of ML beyond supervised methods, i.e., approaches that use unsupervised ML, and conclude that the true potential of ML does not lie in replacing humans but in supporting humans so that human and ML can be integrated into a product that is more than the sum of its parts.

Students' Epistemological and Positional Framing in Uncertain Situations during a Collaborative Design Activity

Navneet Kaur, Chandan Dasgupta
navneetkaur@iitb.ac.in, cdasgupta@iitb.ac.in
IDP in Educational Technology, IIT Bombay, Mumbai, India

Abstract: This study examines students' epistemological and positional framing when they collaboratively resolve uncertainties in a problem-solving process. We qualitatively analyzed three teams' discourse from the sixth standard classroom based on their behaviors in uncertain situations during design activity. We identified four types of students' epistemological framing and three types of positional framing in our data.

Introduction

Students experience uncertainties all the time in academic settings and there has been growing emphasis on ideas like problematizing content (Reiser, 2004) and engendering productive failure (Kapur & Bielaczyc, 2012) to help students meaningfully engage in and learn from uncertainties. However, how learning happens in a situation depends not only on teacher instruction and strategies but also on students' personal beliefs and understanding of the task they engage in and how they view their own and others' participation in that task (Greeno, 2009). We argue that it is crucial to understand learners' propensities in situations fraught with uncertainties for helping students productively grapple with uncertainties. This study explores this direction using 'Framing' as an analytical lens. The term "Framing" is used to describe an individual's interpretation and answer to the question - "What is it that is going on here?" (Goffman, 1974). Framing shapes how people experience situations, develop expectations, and make decisions (Hutchison & Hammer, 2010). For our analysis, we are particularly interested in two types of framing – students' epistemological and positional framing. Students' epistemological framing refers to their expectations and understanding about how to engage in the knowledge that they consider relevant for a task; in this case, the task of resolving uncertainty. Positional framing, on the other hand, refers to how students position themselves and others in their interaction (Greeno, 2009).We examined students' framing in the context of collaborative engineering design tasks since ill-structured nature of the design tasks makes them rich in providing students with opportunities to experience multiple types of uncertainties (Jordan & McDaniel, 2014).

Method

We conducted an engineering design activity in a sixth-grade classroom in a metropolitan city in India. In the study, we asked learners to design a balloon powered toy vehicle that travels straight and smooth for a larger distance. We randomly divided students in the class into groups consisting of either three or four participants to form twelve teams. For data collection purposes, we chose three teams based on the team's potential for providing rich data by virtue of active conversations between the members during the initial phase, where teams discussed problems among themselves. A materials kit was provided to the teams for constructing a prototype. Two primary researchers were present in the class as observers. The primary researchers were accompanied by three teaching assistants (TAs) from the same department. The primary role of the TAs was to handle the logistics related to audio and video data collection.

We analyzed video recordings using a coding scheme developed by Jordan et al. (2014) for identifying all the uncertainties that the team members experienced during the design activity . For each of the unique uncertainty identified in this step, we traced all the episodes where learners attempted to resolve them and then we transcribed these episodes. We then qualitatively analyzed students' discourse in each episode to identify their epistemological and positional framing. The unit of analysis is individual-in-group context (Hogan & Fisherkeller, 2005). We adapted the Interpretation Framework used by Shim et al. (2018) for our analysis. For sampling episodes to present in this study, we chose all the episodes related to the uncertainties regarding the issue of choosing an appropriate nozzle for the design. Students were given three different sized nozzles for building prototypes of their designs, and they had to choose one. This decision problem frequently triggered uncertainty for the team members in the problem-solving process.

Findings

In our data, we found different types of students' epistemological and positional framing. For example, there were instances when learners framed the uncertain situation as inquiry tasks where they engage in the exploration of "what," "why," and "how" questions related to the uncertainty they experienced. For example, students try to resolve uncertainty by figuring out the relationship of the uncertainty to the task goals, finding out factors that cause or influence the uncertainty, and figuring out how they can intervene to alter those factors. In other uncertain situations, learners viewed these situations as a task to be completed or a decision to be made to move ahead and complete the activity assigned to them. In such epistemological framing, students are least bothered about making sense of the events that caused uncertainty; instead, they make quick random decisions to resolve the uncertainty. There were also situations where learners resist engaging in any form of knowledge building as they do not see any epistemic value in pursuing it. In these situations, learners do not share the uncertainty expressed by other team members in the first place. We call this type of epistemological framing "Framing uncertain situation as not worth pursuing." In this frame, learners either ignore the uncertainty or express their unwillingness to participate in the knowledge construction process through their actions. Learners also frame an uncertain situation as "resolvable by an authority figure" when they expect to construct knowledge to resolve uncertainty by receiving direct instruction from an authority figure. Instead of engaging in sensemaking activities, students desire an authority figure like a TA or a teacher to provide immediate solutions to resolve their uncertainty.

Regarding students' positional framing, one of the framings that we observed was where students positioned themselves and the other team member(s) in a "supervisor-assistant" kind of relationship. In this kind of positioning, "supervisor" is regarded as decision-making authority, and the assistant seeks the go-ahead from the "supervisor" for their work. Student positioning oneself as "supervisor" delegates work and direct instructions to those positioned as "assistant." For the cases in this category, we saw an implicit agreement of the roles students positioned for one another where team members positioned as "assistant" readily agreed to follow the "supervisor's" instructions. Students also often positioned themselves and other teammates as legitimate collaborators in the uncertainty resolution process. This kind of positioning is characterized by behaviors where students collaboratively solve uncertainty by seeking and considering each other's help, ideas, suggestions, and viewpoints. A few instances were where a participant treated other team members as unimportant or valueless to the team. Positioning a team member as an "insignificant member" is different from positioning the person as an "assistant." An assistant is regarded as a legitimate member of the team who has a specific role in the uncertainty resolution process. Positioning a person as an insignificant member indicates that the person is considered little to no value to the team's progress or success.

Conclusion

The finding also aligns with the previous studies, which show that students' framing is dynamic (Hutchison & Hammer, 2010; Shim & Kim, 2018). Students respond to various cues and accordingly keep shifting their framings. Expecting that students should always show productive framing like the "inquiry" frame might not be helpful. Instead, it would be beneficial to understand factors contributing to student framing and make efforts to orient them into the productive direction slowly. In future work, we expect to delve deeper into students' framing dynamics and have a nuanced understanding of moment-to-moment shifts in students' responses to uncertainties.

Abstract: We bridge Eco's theory of openness with a connected learning framework to explore how openness supports teaching artists designing for distance learning. We used case study methods to address our overarching question, *what is the value of openness for teaching and learning?* We found that an orientation toward openness supported teaching artists in designing learning experiences that expanded family networks and provided emotional support to connect youth to teachers, peers, and family across settings.

Introduction

Openness has been explored across contexts, including Eco's (1989) poetics of openness, characterized by a plurality of co-existing interpretations of a work of art. Though some educational theorists have discussed how openness and education intersect (e.g., Campbell, 2018), little work has explored how teachers explicitly use openness as a principle for design. In this poster, we bridge Eco's theory of openness with a connected learning framework (Ito et al., 2020) to explore how openness supports teaching artists designing for distance learning, guided by the following research questions: 1) How do teaching artists define openness in the context of their teaching and curriculum? 2) To what extent does an open approach support pathways to connected learning?

Background: Openness and connected learning

Eco (1989) emphasizes the end product of a work of art as a "work in movement," which invites multiple interpretations from the audience. Campbell (2018) extends Eco's poetics of openness as a pedagogical value teachers instill as students apply their "existential credentials" to interpreting works of art. Such open-ended processes are a hallmark of connected learning where openness has meant an openly-networked learning environment and an openness to approaches and settings (Ito et al., 2020). Within a digitally mediated landscape, connected learning recognizes that youth interests, supportive relationships, and future learning pathways are critical to enduring learning experiences (Ito et al., 2020). When bridging the connected learning framework with theories of openness, we can consider how openness intersects with relationship-building, youth interests, and pathways to future opportunities.

Methods

Chicago Arts Partnerships in Education (CAPE) is an established nonprofit arts organization that fosters long-term partnerships between teachers and teaching artists who co-teach inquiry-based, arts-integrated units in K-12 classrooms and after school programs. During the 2019-2020 academic year, CAPE staff curated professional development inviting its teachers and teaching artists to explore Eco's concept of openness within their curriculum and instruction. With the COVID-19 pandemic causing schools to close, openness took on a new form, prompting reflection on issues like space, the body, student voice, and identity (Sikkema, 2020).

This poster presents a case study (Stake, 1995) to describe how CAPE teaching artists designed for openness. We triangulated across semi-structured interviews transcribed via Zoom, original Tumblr posts showcasing work teaching artists shared with their students, and written multimedia reflections. 50% (17/34) of teaching artists participated in the study, a representative sample across arts disciplines, grades taught, and years with CAPE. We selected teaching artist Aram Atamian to illustrate links between connected learning and openness. Aram taught photography and theatre and had been working with CAPE for 1 year, describing himself as an "interdisciplinary diasporan artist." We used an open approach to coding to understand how teaching artists enacted openness within their teaching and mined for evidence of how open approaches intersected with connected learning. We looked for the following themes: *focus on relationships*; *expanding youth social networks*; *sponsorship of youth interests*; *shared practices*; *shared purpose*; and *connecting learning across settings*.

Findings

We found that artists described openness as *flexibility, improv, adapting*; *a focus on process more than product*; *something for which there were intentional structures*; *about following students' lead and continual discussion*; *offering agency*; *choice, and options*; *embracing possibilities*, *exploration, and imagination*; *and 'breaking" the school day.* Openness took on a different form during the pandemic, which stretched teaching artists to be, as one artist put it, "even more open." Teaching artist Aram described openness as "getting it wrong" and "not worrying about getting it right." He created space for "emotional openness" in his lessons through informal life check-ins with students and making space for their lived experiences. He emphasized individual perspective and "continual discussion" when interpreting images. To Aram, openness was intentional and "deliberately structured." In terms of space, he described a shift in the physical layout of the classroom, using openness to rethink and "break the school day." In designing for distance learning online, Aram encouraged activities away from the digital screen such as sending students on what philosopher Guy Dubord named a dérive, or a new walk around a familiar place. For this exercise, Aram invited students to explore their homes from different levels and angles and to observe how the walk shifted their perceptions of familiar spaces and corners.

Openness to strengthen relationships and build networks between families

Aram reflected on how the pandemic created an unexpected opening to *strengthen family relationships* by inviting families to be part of the learning experiences he and his co-teacher designed. For the Poetry Chain project, Aram and his co-teacher introduced students to haikus through reading examples and explicitly teaching the "5-7-5" structure. To begin, one student wrote a haiku, which was then given to a different student to take a photograph representing the haiku. Finally, this photograph was given to another student's parents to write an additional haiku inspired by the photograph without reading the original haiku. The three elements—two haikus and the photograph—were then presented as a cohesive unit, which revealed "humorous, poignant, surprising variations of perspective between generations." A focus on family relationships allowed Aram to *connect learning across settings* to break down the boundaries between school and home and leverage family cultural assets to surface everyday practices that might otherwise go unnoticed. In reflecting on the success of the family photography unit, Aram explained that he "really wanted to design more projects that are explicitly about inter-family collaboration" and find new ways for students and families to purposefully interact. By operating from a place of "emotional openness," Aram highlighted the value of building and expanding upon youth social and family networks that could open new pathways to learning. Families can be positioned as experts who connect students to resources needed to further their interest-driven learning, including necessary materials, a place to do their work, and discipline-specific expertise (Ito et al., 2020). Social networks within the class created feelings of connectedness across families and sparked additional ways to connect to resources and opportunities.

Discussion

In this poster we demonstrated how teaching artists' orientation toward openness supported the design of online learning experiences that expanded inter-family networks and provided emotional support to students. Implications extend how openness and connected learning manifest in learning environment design, with an emphasis on how openness was translated through teaching artists' pedagogy. Our study emphasizes the value of cultivating supportive relationships between teachers and students and connection-building through family networks. Through intentional design choices motivated by openness, teaching artists can create connection pathways that strengthen family relationships and connect learning across settings.

Scaling Teacher Candidates' Family Engagement Training Through Simulations and Artificial Intelligence

Rose Sebastian, Debajyoti Datta
Rs9rf@virginia.edu, dd3ar@virginia.edu
University of Virginia

Abstract: This study explores a new technique to expand family engagement practice opportunities for teacher candidates, who often have limited opportunities to build family engagement skills. We designed a standardized, simulated family conference and developed a performance rubric. The rubric allows performance to be scored automatically, using semantic similarity analysis techniques, as well as by humans. This study demonstrates the potential of simulations and NLP techniques to create novel practice opportunities for teacher candidates.

Keywords: scale, family engagement, NLP, teacher education, simulations

Introduction

The overwhelming majority of novice teachers have not been well prepared on how to interact with students' families and on how to run family conferences (Dotger, Harris, & Hansel, 2008). Family conferences, also known as parent teacher conferences, happen only a few times a year and can build or damage the home-school relationship (Potter & Bulach, 200). Building teacher candidates' expertise requires realistic practice opportunities, which have been challenging to provide in field placements and coursework (Dotger et al., 2008). Some teacher educators have begun integrating simulated family conferences into their coursework as a way to increase teacher candidates' practice opportunities (Dotger et al., 2008; Walker & Legg, 2018). Simulation technologies, such as Mursion's mixed-reality platform, could allow teacher preparation programs to offer family engagement practice opportunities at a larger scale. Mursion provides an animated classroom where teacher candidates interact with student avatars that are controlled in real time by a live actor. The technology allows for standardized practice opportunities and structured transcripts that can be analyzed through NLP techniques. NLP techniques focused on semantic understanding of text have been used to automate the scoring of student work (Litman, 2016). NLP techniques have the potential to transform scoring and automate feedback for family conferences as well. In this study, we explore new ways to provide candidates with family engagement practice through integrating simulations and machine learning.

Methods

Development of standardized scenario and scoring

In spring, 2020 105 teacher candidates participated in two rounds of a seven minute simulated family conference with the father of a high-achieving, but shy student in their simulated classroom. During the meeting, the father interrupted at five set time points with questions about the teacher's experience, worries for his child, and personal information about his own challenges at work. After the simulation, each candidate's two simulation sessions were transcribed and scored using a researcher designed rubric. The rubric, which draws on Walker and Legg's (2018) rubric but is highly tailored to this scenario, has nine scoring categories, focused on teacher's rapport building during the opening of the conference and how the teachers respond to challenging comments and empathetic opportunities provided by the parent. Candidates receive a score of one, low, to three, high, in each category and the scoring rubric includes five exemplar responses at each scoring level. For example, when dad says, "Experience makes a difference and her other teachers had so much more experiences," candidates received a score of three if they responded positively, such as by saying, "I know that I'm new to teaching. That's why I wanted to reach out to you." Twenty percent of the transcripts were double coded with 82% accuracy.

Using semantic similarity analysis to automate performance scoring

We then evaluated the semantic similarity of text with a pre-defined human rubric (See Figure 1). Our approach to this evaluation includes both category identification and evaluation within each category. To identify the category, we use state of the art text classification approaches based on transfer learning (Devlin et al., 2018). Transfer learning approaches require less data for classification and are also more robust to out of distribution word patterns and usage. These techniques allow us to identify if a response belongs to, for example, the greeting or student strengths category. Within each category, evaluation is iterative. Since we have delineated evaluation criteria and exemplar responses, we can measure semantic similarity in each category to score the responses. We can examine how closely a response in a category matches exemplars for that category. For example, "I'm so sorry to hear that. Is there anything I can do?" is highly similar to "Okay, are you doing okay?... Well, I'm very sorry to hear that," and dissimilar from, "If you don't mind, let's go back to Katie." For evaluation, we followed STS benchmarks (Semantic textual similarity wiki, n.d.) and used Pearson correlation coefficients to score the semantic similarity. Downstream training of the task will improve semantic similarity across all categories.

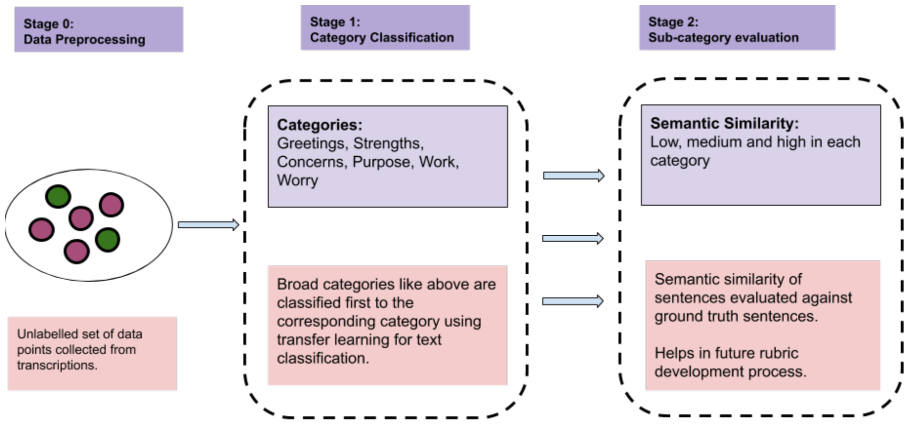

Figure 1. Evaluation protocol and architecture of NLP system.

Results and conclusion

Family conferences are two-party conversations that can go in many different directions based on the input of each party, making them challenging to standardize. We found, however, that many teacher candidates, even without training on conference, begin with a greeting, a statement of the student's strengths, and information on the teacher's concerns and the meeting's purpose, creating a natural standardization for scoring. We also used standardized lines to understand how teacher candidates respond to challenging comments and empathetic opportunities. We found that candidates' responses to empathetic opportunities varied in part on how personal the disclosures were, with teacher candidates showing more ease when the opportunities were about the child than when they were about the parent. Further, the two step classification process enabled us to build robust downstream classifiers using the latest developments in NLP and deep learning. In future, we plan to train models with larger datasets to make the evaluation process more robust. We also plan to use the findings from the machine learning analyses and what we have learned about candidates' strengths and needs to develop automated feedback on the scenario. Students and their families deserve teachers who are ready to build partnerships on day one. While our work continues, our novel approach of building NLP techniques into simulations has the potential to transform pre-service teachers' practice and feedback opportunities in family engagement and beyond.

A Dynamic Social Network Approach to Capturing Shared Regulation Interactions in Collaborative Learning

Abstract: Socially shared regulation, where students jointly coordinate understanding, motivation, and behaviors, is fundamental to successful collaboration. However, the social dynamics at the core of regulation are difficult to detect and understand. We apply relational event modeling, a dynamic network approach, to examine the interactional dynamics between students in different regulatory processes in a project-based learning engineering context. Findings suggest that reciprocity and shared partnerships were associated with how likely students might interact. Female students were less likely to engage in planning and monitoring exchange. We discuss implications for promoting equal participation in collaborative learning.

Introduction

To promote effective collaboration, students need the socially shared regulation strategies to jointly coordinate motivation, cognition, and behaviors (Hadwin, Järvelä, & Miller, 2011). Understanding the processes and social contexts in which students regulate shared efforts is important to detect and promote effective collaborative learning. Relational event modeling (REM) offers key affordances for understanding social dynamics in different regulation processes. First, this approach allows us to account for interactional histories between student dyads and examine how these interactions differ between regulatory processes. Second, our REM models consider potential individual differences in interaction patterns. The following questions guided our research:

RQ1. What interactional dynamics may characterize different regulated learning processes?
RQ2. How do interactional dynamics in regulated learning differ by gender and leadership positions?

Methodology

This study was part of a larger project that focuses on collaborative group exchange in a two-term, first-year project-based engineering course in Western United States. Our data came from 22 first-year students in four teams, who were taking the elective course as introduction to engineering. The sample represents the overall course demographics (22.7% women, 72.7% Latinx or Asian students).

Analyses drew from the audio and video transcripts of the teams' in-person discussion in lab at the midpoint of the semester (8-hour audio data). At this point, students had been introduced to fundamental engineering principles and started developing their group products: creating autonomous quadcopters or fitness trackers. We watched the videos of team discussion to denote the direction for the exchange. Then, we identified shared regulation by selecting the discourse chunks where students were identifying shared tasks, co-planning strategies, and executing tasks towards common goals ($n = 2{,}462$ conversational turns). We coded these discourse segments by individual talk turn for different processes of task understanding, strategic planning, execution, progress monitoring, and reflection (Nguyen, Lim, Wu, Fischer, & Warschauer, 2021). We achieved substantial agreement among the coders on 10% of the data (Cohen's $\kappa = .87$). We then applied REM on the coded dataset.

Using the REM method, student exchange can be visualized as a network of nodes (e.g., students), edges that indicate the exchange directions (e.g., sender or receiver), and the strength of connections between two nodes (e.g., frequency). A relational event can be defined as something generated by a student, that is directed toward one or more students at a particular point in time (Butts, 2008). Intuitively, the REM is a logistic regression model that predicts the probability of the next event (i.e., next interaction between students).

We ran separate REMs for the overall dataset ($n = 2{,}462$ turns), and for separate processes: Plan ($n = 435$), Execute ($n = 1{,}563$), and Monitor ($n = 216$). We excluded subsets of Task Understanding and Reflection, due to their low occurrences. Because we did not find differences in the trends of relational interactions in separate REMs for each of the teams, we focused on reporting the overall patterns. Building on prior work, our REMs (Table 1) included past events as predictors. For example, *reciprocity* (student A->B->A) plays a key role in helping teams overcome setbacks (Järvelä, Järvenoja, & Malmberg, 2019). Because the process involves multiple group members working towards shared goals, there could be *participation shifts*, where a group member who is not involved in the conversation joins the regulatory exchange (student A->B->another student Y). Alternatively, there could exist *recency* effects, where two students who are already engaged in the initial conversations sustain regulatory actions (A -> B -> A -> Y). Finally, we accounted for *outbound shared partners* (i.e., if A and B send exchange to similar partners; A and B are more likely to interact). We also included individual attributes, namely gender (female = 1) and leadership position in the group (leader = 1).

Findings

On average, within the course of the lab session, students sent 10.97 exchange ties, SD = 6.06, and received 10.31 ties, SD = 6.48. Non-parametric Mann-Whitney-U tests suggest no significant differences in the number of exchanges sent and received by female versus male students (send: W = 34; $p = .33$; receive: W = 30; $p = .20$), or group leaders versus others (send: W = 14; $p = .07$; receive: W = 19; $p = .16$).

RQ1: Reciprocity and Shared Partners are the Norm across Regulation Phases

We first examined the extent to which past interactional norms predicted subsequent shared regulation. For the overall regulation and subprocesses of planning, execution, and monitoring, we found that reciprocity significantly predicted the likelihood of an exchange (OR = 5.786, SE = .115, $p < .001$).

We found that the numbers of students that two individuals both sent exchange to affected their future rates of interactions. This likely reflects a working norm that we qualitatively observed in the project-based engineering groups, where students often divided themselves into smaller groups to work on subtasks. Consequently, partners who worked on the same subtasks may be more likely to send exchange to one another.

Notably, we found that a participation shift in progress monitoring, where the receiver of an exchange was 2.27 times more likely to direct the next exchange to another student. An example for this participation shift is when the groups were working on different subtasks and routinely checked in with one another.

RQ2: Female Students were Less Likely to Engage in Planning and Monitoring

We did not find difference in the likelihood that male and female students sent an exchange in the overall sample or in the execution phase. However, female students were .80 times less likely to engage in an interaction in planning, and .65 times less likely in strategic monitoring. Successful participation in all regulatory phases, particularly looping between planning and executing, has been associated with higher quality engineering design (Ahmed, Wallace, & Blessing, 2003). Our findings highlight the need for instructional and collaborative practices that promote equity and inclusivity across all regulatory phases. For example, in-time, direct instructional scaffolds that emphasize the input of all team members have shown promise in helping students to engage in self and shared regulation processes (Järvelä et al., 2016).

Conclusions

We explore regulation processes from the novel perspective of past social relations. We found that reciprocity and shared partnerships predicted how likely students might interact. We observed differences in regulatory processes, which suggest that not all learners were equally involved in dyadic exchange in each process. Although there was no difference in the number of exchanges on a surface level, our more nuanced analyses reveal different gender attributes and relational dynamics that contribute to student interactions, with key implications for their experiences and learning outcomes. We illuminate the affordances of accounting for individual attributes to acquire a deeper understanding of the learning processes.

Participatory Design of Game-Based Math Learning Platform: Teacher-Researcher Negotiation and Collaboration

Chih-Pu Dai, Fengfeng Ke, Yanjun Pan
cd18m@my.fsu.edu, fke@admin.fsu.edu, yp10d@my.fsu.edu
Florida State University

Abstract: Teachers' involvement legitimizes learning artifacts design, development, and implementation. We present a case study on the teacher-researcher participatory design of a game-based math learning platform. A thematic analysis with the empirical data from two teacher workshops indicated (1) problem spaces that frame participatory design; and (2) tool that supports sustainable participatory design of game tasks. We discussed suggestions for teacher-researcher participatory designs for DGBL.

Introduction and theoretical background

The educational affordances of digital game-based learning environments (DGBL) had drawn much attention of educational researchers and practitioners. However, it is still a challenge to implement game-based learning in the classrooms. The design and implementation of game-based learning technologies cannot be successful without the involvement of teachers (Matuk et al., 2016). Research-practice partnerships, more specifically, teachers' participatory co-design with researchers should be emphasized in the process (Coburn & Penuel, 2016; Matuk et al., 2016). Teachers' participatory co-design for game-based learning is a bidirectional and reciprocal participation between researchers and practitioners. The aim is to design a more practicable learning environments and increase the scalability and sustainability of implementation (Coburn & Penuel, 2016). Participatory design engages multiple stakeholders in envisioning and prototyping of learning environments in creative design activities beyond decision-making; through positioning and situating stakeholders' rationale and input, the design can be enhanced (Bjögvinsson et al., 2012; Muller & Kuhn, 1993). In participatory design, teachers and researchers could bring different point of views. These exchanges of view, negotiation, and collaboration should be rooted in and focused on designing learning technologies to solve an educational problem with mutual agreement. Bjögvinsson et al. (2012) put it as *designing, staging,* and *infrastructuring* (p. 103). Both teachers and researchers gain legitimate participation, working on artifacts, and brainstorming about how to make the design artifacts more scalable and sustainable for use in the classrooms.

An increasing focus have been given to understanding participatory design research and partnerships between communities of researchers and practitioners (Coburn & Penuel, 2016; Matuk et al., 2016). However, there is still a gap in the literature regarding the landscape of the participatory design and "what happens" in the process despite an extensive advocacy. Thus, the following research question remains underexplored: *how do teachers and researchers negotiate and collaborate in the participatory design of a game-based math learning platform?*

Method

We collected data from the teacher workshops conducted in the southeastern US for the purpose of designing an architectural game-based math learning platform called *E-Rebuild* (Ke et al., 2019) as well as exploring game-based pedagogies with teachers. We used two artifacts of *E-Rebuild*: the learning game *per se* and the level editor (for customizable level design with the teachers). The game was intended for middle school students. We invited 10 teachers from two schools to participate in both teacher workshops and the participatory design process (Muller & Kuhn, 1993; Bjögvinsson et al., 2012). The first workshop was conducted with 3 teachers from a suburban charter school. The second workshop was held for seven teachers from a suburban public school in a fourteen-week design-based cycle. Each workshop was conducted for about eight hours. To study design-based teacher-researcher collaborations, we adopted a case study approach (Yin, 2009) for an in-depth and in situ investigation of the negotiations and collaborations between teachers and researchers. We collected data from participatory observations, screen recorded videos, semi-structured interviews, and design artifacts analysis. In the first round of data analysis, we reviewed the videos and dataset with open-coding technique to identify informative codes. Next, we engaged in the second wave of data analysis with axial coding and selective coding; we used a constant comparative method for emerging themes identification. Multiple data sources as well as reflexive journals and memos during two cycles of data analysis established trustworthiness.

Results

Problem spaces that frame participatory design

In participatory design, a mutual understanding of the *problem space* that both teachers and researchers are working on is critical. The knowledge sharing started from the recognition of the problem spaces. Researchers and teachers were observed engaging in stages of building shared understanding and orienting the *problem space* for participatory design before proceeding to the knowledge sharing stages. Teachers from two schools first acknowledged the challenges they are facing in math education: *lacking real world examples*. This shared understanding of problem was identified between the teachers and researchers. Both agreed that DGBL could be infused to resolve this problem. Specifically, the game environments and features designed could create *connections* between content learning and disciplinary practices: "*If you are going to school and teaching kids numbers, the concept of numbers, they have a purpose. You don't just go to school and put down on a paper and tell them you have to do it*" (Teacher G).

After the problem spaces have been mutually agreed, teachers were engaged in gameplay to visualize and concretize the artifacts to be co-designed. During the process, teachers contributed ideas for the game refinement by considering how the students would perceive what they are experiencing in the problem spaces. For example, one teacher commented, "*The ratio and proportion ones, they are…our kids probably can do that. But then…some bizarre ones they have to figure out. Like this one (while pointing the mouse to a Challenge of Ancient Mesopotamia in the game environment)"* (Teacher F). This perspective-taking stance is a common strategy teachers used during design collaborations. Furthermore, teachers and researchers were counterbalancing and reconciling the philosophy of teaching and learning with DGBL. Teachers brought up the reality of limited time in the classroom that makes it harder for the students to practice math thinking in the constructivism DGBL. They envisioned how DGBL could possibly complement their math instruction by saying, "*It should be used more for an enrichment thing*, *it gives more hands-on, yeah, I can see that*" (Teacher H).

Tool that supports sustainable participatory design of game tasks

When using the level editor, teachers asked the possibilities of creating a community *for* teachers to share customizable design artifacts and improve practice, "*If there is a teacher, say, in Lea county* (pseudonym)*, she made a…a question, on the same concept or levels that I am using, is there a thing that I am able to see, so that I won't have to recreate"* (Teacher I)? Moreover, teachers proposed to involve students in using the level editor as a learning-by-making tool, *"If the students use the level editor to build their own game, they will better understand the concept*, and *they will see why the problem looks like that, and they will tell the story based on that*" (Teacher H). These ideas suggested that the level editor supported sustainable participatory design for more game levels.

Conclusion and implications

The study findings portrayed teacher-researcher participatory design. They underscored the phenomena of teachers' perspective-taking as students in providing insights for participatory design in problem spaces. They also indicated the role of a participatory design tool in enacting or supporting a community for teachers' collaborative and participatory design of game-based learning tasks or artifacts. We argue that participatory design of teachers with researchers should emphasize teachers' voices to transform the process of design and implementation of DGBL, and the participatory design process should be sustainable to ground DGBL in practice.

Designing Narratives in Multimodal Representations for Game-Based Math Learning and Problem Solving

Chih-Pu Dai, Fengfeng Ke
cd18m@my.fsu.edu, fke@admin.fsu.edu
Florida State University

Abstract: Narratives as a game feature constantly yield mixed results for learning in the literature. In this case study, we studied the design of narratives in multimodal representations for game-based math learning and problem solving with 27 student participants. Results indicated that narratives with multimodal representations situated in the game world appeared to foster math sensemaking and reasoning. However, decontextualized math problem solving was also observed. Implications for narratives and multimodality design were discussed.

Introduction and theoretical background

Digital game-based learning (DGBL) environments have been used to provide authentic mathematical experience—exploring, formulating, and experimenting with mathematical hypotheses in the game world. Although the overall effect of DGBL for math is promising, prior research findings regarding specific design features remain controversial. The effects and design features of narratives, in particular, remain murky.

According to Bruner's (1964) learning theory, an individual's meaning making process involves three modes of representation: enactive representation (e.g., motor response or action: maneuvering in-game objects), iconic representation (e.g., images, graphics, or objects in a game), and symbolic representation (e.g., symbol systems or texts). These three modes of representations can be coordinated as *multimodal representations* that set a foundation for the design and interpretation of learning in the game space (Ainsworth, 2006; Ke & Clark, 2020).

The current case study aims to examine narratives in multimodal representations for game-based math learning. Particularly, the following research question is investigated: *What are the impacts of narratives in multimodal representation on learning in a game-based math learning environment?* In the current study, we employed a 3D architectural math learning game called *E-Rebuild* (Ke & Clark, 2020). The system of narratives in multimodal representation in *E-Rebuild* consist of (1) task narratives (i.e., explaining the task of each level for the learners), (2) contextual narratives (i.e., providing a storyline at the beginning of the task narratives), (3) math notation (i.e., a mouseover feature inscribed on the game creates), (4) concrete stimuli (i.e., tool to retrieve symbolic math information), and (5) environmental cues (i.e., popups reminding learners what went wrong). Measuring, trading, building, and allocating items in the 3D game world are major game actions designed to integrate mathematical learning actions while simulating architecture-themed problem-solving processes.

Method

To examine how the players use and interact with the narratives designed in the multimodal representation, we adopted a heuristic case study method in which each participant is a case (Merriam, 1998). As part of a longitudinal design-based research, 27 college students with variant genders, gaming experiences, and academic backgrounds were recruited as users to inform our designs in this study (Merriam, 1998). These participants played the game for one and a half hours individually, with a researcher closely observing the gameplay and providing technical support as needed. Immediately after the gameplay, a thirty-minute semi-structured interview was conducted to further collect the data on participants' gameplay experiences and perceptions. Rich data were triangulated between observations, video recordings, semi-structured interviews, and gameplay artifacts created by the learners. We performed three phases of data analyses: (1) open and descriptive coding techniques. (2) revisited the codes, revised and developed themes emerged from the data; created visuals and displays to demonstrate the relationships of the themes delineated. (3) executed queries. We wrote memos and kept reflective journals, as well as analyzed deviant cases for confirmability and credibility (Miles et al., 2020). We focus on general themes and highlight salient cases with displays in this paper.

Results

Narratives in multimodal representation supported math problem solving

In general, the narrative system in multimodal representation functioned to support math problem-solving exploration. To elaborate, all participants started their gameplay by reading the task narratives. However, it wasn't natural for some participants to engage in math problem solving after reading the task narratives. Specifically, a random trial-and-error stage was observed, as demonstrated in the following example (See Figure 1, Right). After several rounds of trial-and-error, the narrative system prompted Participant 19 to purposefully engage in math reasoning and problem solving. He collected the task-related math information (*the height and width of the container*) from distributed task narratives (e.g., in the Task Panel and object-related tool tips). He then organized the task information while adjusting his hypothesis with the task (see *Stage 3* in Figure 1, Right). He strategically and carefully adjusted the number of families to each container. During the process, he carefully read the math notations while calculating the space needed in the 3D game world. His math reasoning process was prompted and mediated by the narrative system in multimodal representation that legitimized math-related gameplay strategies during game-based problem solving.

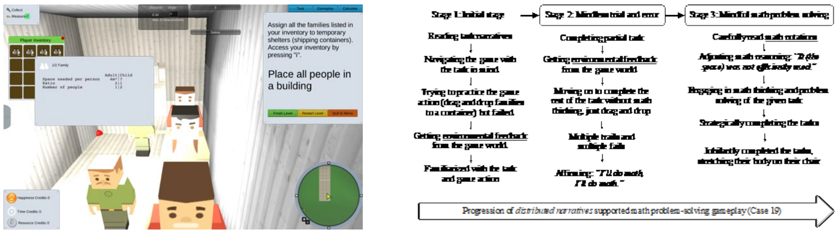

Figure 1. (Left) An example of narratives system in the game. (Right) A visual display of Participant 19's gameplay supported by distributed narratives

"Decontextualizing" math problem and the narratives

Although a body of evidence from participants supports that narratives in multimodal representation are useful in mediating math problem solving in the game world, some case analysis still indicated a deviant phenomenon. Take participant 4 for example, the multimodal narrative system did not make him cognitively flexible. In a level where he needs to process the concept of ratio in the math notation to tackle the design task, he got stuck and showed frustration. Instead of interpreting the given math notation, he used the measure tool to *measure the height* of the game object to calculate the *surface area* in square meter: "*when I do math, I feel like to measure*." He kept trying the same strategy rather than searching for alternative solutions or clues embedded in the game world. This behavior demonstrated that he was not flexible in terms of math thinking and problem solving given his consistent efforts contributed to the same solution or strategy. The case highlighted the essential role of providing a mechanism in multimodal representation to promote flexibility in experimenting with and comparing alternative problem-solving strategies.

Conclusion and implications

In this case study, distributed narratives designed in the math learning game appeared to coordinate and enhance math sensemaking and reasoning (Ainsworth, 2006). Yet, this learning process did not naturally occurred in a single form of representation (i.e., task narratives in symbolic representation). Instead, it was the narratives in multimodal representation that mediated and prompted mindful math problem solving. There are two implications for designing narratives in DGBL. First, DGBL narrative features should be intrinsically integrated into the game environments to provide a coherent system that engages learners in mindfully doing and thinking math. Second, deviant cases speak to the importance of designing narratives that stimulate cognitive flexibility. Future research should continue to explore how narratives can afford multimodal feedback for flexible math problem solving.

Assessing Pedagogical Practices to Support Self-Regulated Learning in Science

Idit Adler, Tel Aviv University, iditadler@tauex.tau.ac.il
Liat Copel, University of Michigan, liatc@umich.edu
Cathie Norris, University of North Texas, cathie.norris@unt.edu
Elliot Soloway, University of Michigan, soloway@umich.edu

Abstract: The goal of this study is to examine how teachers implement opportunities for students self-regulated learning (SRL) provided by computer-based student-centered and interactive digital curricula, through pedagogical practices in natural classroom contexts. To meet this goal, we developed an observation tool that distinguishes varying extents to which teachers apply SRL-supportive practices. Our ultimate goal is to raise teachers' awareness of best practices with respect to SRL, thereby supporting them in improving their teaching.

Keywords: Educational technology, pedagogy, self-regulated learning, student-centered learning

Major issues and significance

Self-regulated learning (SRL) is the proactive process through which students become masters of their own learning and performance (Pintrich, 2000). Supporting students in developing their SRL skills is regarded as one of the major goals of education, and is important from both cognitive and socio-emotional perspectives. SRL is not spontaneous, and can be developed by means such as: Scaffolded computer-based learning environment, student-centered curricula, and teacher's pedagogy and instructional practice. Although observing teachers' promotion of self-regulated learning in naturalistic classroom settings is a promising approach for both theory and practice, studies that apply this method are rare. Therefore, the overarching goal of our research is to illuminate teachers' pedagogical practices with respect to SRL. To meet our goal, we developed an observation tool, and used it to examine the degree to which different teachers take advantage of the opportunities for SRL afforded by a computer-based student-centered and interactive digital curriculum, in a typical classroom context. Ultimately, our research strives to optimize teachers' pedagogical practices.

Conceptual and theoretical framework

In this study, we adopt the Pintrich (2000) framework, which focuses on different kinds of SRL strategies, and lends itself more to large-scale quantitative investigations that can inform interventions to support specific SRL strategies. According to Pintrich (2000), SRL is characterized by four phases: (1) Forethought, planning and activation; (2) monitoring; (3) control; and (4) reaction and reflection. Each of these phases has four different areas for self-regulation: cognition, motivation/affect, behavior and context. For our current study, and in this paper, we have focused on the cognitive dimension of SRL, while further research will examine additional aspects of self-regulation.

Methods and data analysis

Three female, 3rd grade elementary teachers from different schools in a Midwest US state participated in this study. Each of the teachers had more than a decade of teaching experience, and had classes ranging from 28 to 32 students with similar demographic makeups. The teachers engaged students in a NGSS-aligned project-based learning science curriculum using *Collabrify*, a computer-based learning environment. In *Collabrify*, lessons are implemented as digital roadmaps, which visualize the lesson as a concept-map, where students tap a linked node in order to perform a learning activity. The digital roadmap lessons provide opportunities for students to navigate and control their learning to varying degrees. All teachers and students were new users of *Collabrify*. We conducted videotaped observations, coupled with informal interviews. Using both a priori theory of SRL (Pintrich, 2000), and a grounded theory approach using constant case comparison (Hoops, Yu, Wang & Hollyer, 2016), we developed the Opportunities for Self-Regulation observation rubric (Opp4SRL) that enables examination of teachers' implementation of a roadmap lesson in their classroom. For each of the four phases within the cognitive aspect of SRL, we identified four levels of instructional practices (Levels 1-4). The higher the level, the more supportive of SRL is the teachers' pedagogical practice within that phase (see example for *planning* in Table 1, the complete Opp4SRL rubric will be presented at the conference). We used the Opp4SRL rubric to code and score teachers' pedagogical practices with regard to SRL in three 45min lessons per teacher.

Table 1: An example of the Opportunities for Self-Regulated Learning (Opp4SRL) rubric

Planning (a sub element within the *forethought, planning and activation* phase)***: (Level 1) Provides no overview of the lesson:*** Does not provide the students with an overview of the*;* ***(Level 2) Provides an overview and imposes lesson plan:*** Provides students with an overview of the lesson, and enables only one possible path to achieve the goals of the lesson; ***(Level 3) Provides an overview and negotiates lesson plan***: Provides students with an overview of the lesson, and provides multiple optional paths to achieve the goals OR exhibits willingness to negotiate the paths to achieving the goals; ***(Level 4) Provides an overview, negotiates lesson plan and provides students with strategies to choose between options***: Provides students with an overview of the lesson, and provides multiple optional paths to achieve the goals OR exhibits willingness to negotiate the paths to achieving the goals, explains the differences between them, and provides the students with strategies that enable them to make an informed decision about which path to follow.

Results and findings

The Opp4SRL observation tool enabled us to discern among teachers' practices, and identify varying levels of supportive or constraining SRL pedagogies. Table 2 presents examples for several sub-elements within the *forethought, planning and activation* phase. While teachers' scores varied, we identified three distinct types of instruction: *Pre-SRL* (*Teacher A*)- the teacher fully regulates students' learning and provides almost no opportunities for students to engage in SRL; *Developing SRL* (*Teacher B*)- the teacher mostly regulates students' learning but provides some opportunities for engagement in SRL; *Proficient SRL* (*Teacher C*)- the teacher positions herself as a guide, and enables students to self-regulate their learning, while providing the necessary strategies. Our results indicate that while computer-based student-centered and interactive digital curricula are prerequisites, teachers' pedagogical practices have a crucial role in supporting students' engagement in SRL.

Table 2: Examples for teachers' practices with regard the forethought, planning, and activation phase

Teacher A	**Teacher B**	**Teacher C**
Planning: Provided only a brief description of the lesson before diving into the lesson. She did not use roadmap as a tool to support planning, and is task-by-task oriented - all students complete the same tasks together (*Level 1*)	***Planning:*** Though projected the roadmap on the board, *Teacher B* did not use it to provide students with an overview of the lesson but rather to support her teaching. Task-by-task oriented instruction (*Level 1*)	***Planning:*** Provided an overview of the lesson using roadmap as a visual scaffold. Although all students followed the same path with the map, they could complete their activities at their own pace. During the lesson, students moved around the class involved in different activities (*Level 2*)
Prior knowledge activation: Only the teacher provided the necessary prior knowledge for the lesson. Although she used prompts to trigger students to answer, it was mostly the teacher who answered the questions (*Level 2)*	**Prior knowledge activation:** Conducted comprehensive discussion and triggered students to share prior knowledge. She addressed knowledge associated with both content and inquiry practices (*Level 3*)	**Prior knowledge activation:** Triggered and encouraged students to bring in their prior knowledge and ideas. She directed students to additional resources (e.g., books) and explains why they should refer to them (*Level 4*)
Meta-cognitive knowledge activation: When engaging in modeling, *Teacher A* reminded students to label their components clearly, however did not explain to the students the rationale behind this strategy. No additional strategies were observed (*Level 2)*	**Meta-cognitive knowledge activation:** Explicitly addresses many strategies, such as: discussions with elbow partners, re-read questions, state in your own words. Does not provide guidance about the applicability of strategies (*Level 2)*	**Meta-cognitive knowledge activation:** Before completing a collaborative activity, *Teacher C* facilitated a discussion about collaboration and knowledge building: She triggered students to share strategies and debated their effectiveness. She enabled students to choose which strategy to implement (*Level 4*)

Boundary Spanning Roles and Power in Educational Partnerships

Christopher M. Wegemer, Jennifer R. Renick
cwegemer@uci.edu, jrenick@uci.edu
University of California, Irvine

Abstract: Navigating boundaries between contexts is essential for RPP effectiveness, yet much work remains to establish a conceptual framework of boundary spanning in partnerships. Our longitudinal case study draws from three long-term partnerships to construct a model of boundary spanning roles in RPPs from a graduate student perspective, with particular attention to the ways in which power permeates partnership work. We aim to promote the development of effective strategies to support graduate student boundary spanners.

Introduction

Research-practice partnerships (RPPs) represent a promising strategy for improving educational systems. The success of partnerships depends on adept navigation of sociocultural and organizational differences (Farrell, Harrison, & Coburn, 2019). Boundary work has been a prominent subject of scholarly study, particularly in educational contexts (Akkerman & Bakker, 2011; Weerts & Sandmann, 2010), but the conceptualization of boundary spanning in RPPs remains an emerging topic (Penuel, Allen, Coburn, & Farrell, 2015). The structure and effectiveness of RPPs depend on boundary spanning roles and practices that are frequently relegated to graduate students. Despite the crucial positionality of graduate students, research that explicitly examines their experiences and roles in educational partnerships is limited.

The present study builds on the conceptual work of Penuel et al. (2015), Akkerman and Bakker (2011), and Weerts and Sandmann (2010) to develop a model of boundary spanning in RPPs. Particular attention is given to power dynamics and equity (Denner et al., 2019). We draw from qualitative analyses of three long-term partnerships to construct a pragmatic and theoretically salient framework. By elaborating a model grounded in the experiences of graduate students, we aim to inform new methods of supporting early career scholars, encourage the development of effective RPP strategies, and more broadly, increase understanding of experiences and processes at educational boundaries. We pursued three overlapping research questions:

1. What are the boundary spanning roles of graduate students in educational partnerships?
2. What features of RPPs can influence graduate students' role negotiation?
3. How do power dynamics manifest in graduate students' boundary navigation?

Methods

Our present study is based on three RPPs that involve two school sites and one out-of-school program. As graduate student researchers employed by our university, we conducted the bulk of the work in the RPPs. The data sources for the present study were artifacts and field notes from partnership meetings spanning three years. We structured our analyses as a longitudinal case study. First, we organized all of our data materials by interaction type. We then reviewed the data with particular attention to our own positionality in the partnerships. Themes from each type of meeting were inductively generated. We triangulated the themes using available data sources and iteratively conducted rounds of review to ensure cohesion and accuracy of the generated themes, as well as establish relationships between the themes.

Findings

In response to our research questions, we developed a model of boundary spanning based on our experiences as graduate students in educational partnerships (Figure 1). Our framework elaborates on boundary spanning roles shaped by contexts of interaction and partnership characteristics across multiple dimensions.

Contexts

We identified three contexts in our partnership work: practitioner site, university site, and informal spaces. Examples of each type of space are shown in Figure 1. The contextual categories are consistent with Penuel et al.'s (2015) distinctions between researchers and practitioners in joint work at boundaries.

Partnership dimensions

We identified four dimensions that describe the systems in which partnership work is embedded: organizational, cultural, relational, and historical. Examples of features of these dimensions are provided in Figure 1. All partnership roles were influenced by partnership characteristics in each dimension. Power often manifested as control over resources that are relevant in each domain.

Role spectrums

We found five distinct spectrums on which our roles varied. First, consistent with Weerts and Sandmann (2010), our attention could be characterized as between entirely partner-focused or entirely university-focused extremes. Second, the type of tasks that we engaged in could be described as some proportion of technical tasks and socioemotional tasks (also aligned with Weerts and Sandmann, 2010). Third, our role varied between that of an experienced expert and an inexperienced novice, depending on the context and characteristics of the partnership. Fourth, under some circumstances, we needed to enact a role as a partnership advocate, whereas in other situations, a critical perspective was required. Fifth, sometimes we took on (or were given) a role as an authority with decision-making responsibility, whereas in other instances, we were submissive or passive recipients. Power was unevenly distributed across the role spectrums. Depending on the particular context and circumstances, different roles were imbued with varying degrees of power. A general level of empowerment was necessary to allow the freedom to explore (or openly discuss) our own roles and the roles of others. This role flexibility was essential to the effectiveness of our partnership work.

Conclusion

Locating ourselves on each of the five spectrums provided a comprehensive description of our boundary spanning roles in any given situation in the partnership. The prominence of each role depended on which aspects were salient for the specific partnership interactions and circumstances. We found that responsively acting in a partnership entails intentionally adapting roles to meet the conditions of the context and dimensional characteristics of the partnership work. Our research builds on emerging RPP literature regarding boundary work (Penuel et al., 2015), roles (Farrell et al., 2019), and power (Denner et al., 2019). A full documentation of our study is currently in press at *AERA Open*.

Identifying and Coding STEM Interest Triggers in a Summer Camp

Sherry Yi, Matt Gadbury, H. Chad Lane
fangyi1@illinois.edu, gadbury2@illinois.edu, hclane@illinois.edu
University of Illinois at Urbana-Champaign

Abstract: Our work investigates interest triggering, a necessary component of sustaining and developing long-term interest in STEM. We gathered interview data from middle school aged learners (N = 7) at a science-focused Minecraft summer camp over a period of one week. We first identified STEM interest triggering episodes, then categorized each episode based on codes developed previously by Renninger and Bachrach (2016). Our initial findings show differences in the frequency of interest triggering episodes across individuals and suggest that *personal relevance* and the use of Minecraft played prominent roles.

Keywords: videogames, technology, summer camp, interest development, STEM learning

Introduction

Our research examines how interest, operationalized as a psychological construct and motivational variable (Renninger & Hidi, 2016), can be identified in student interviews regarding their experience in a science-themed summer camp. We define interest as heightened attention and engagement, as well as continued voluntary re-engagement with subject matter (Hidi & Renninger, 2006). We build on and address the gaps within existing work about interest triggering in out-of-school learning settings. Renninger and Bachrach (2015) analyzed interest triggers of middle school-aged learners in an out-of-school biology workshop where they elaborated on a five-step content analysis on existing interest literature and theory. This work produced eight codes describing triggers for interest within the science workshop context: *autonomy, challenge, computers/technology, group work, hands-on activity, instructional conversation, novelty*, and *personal relevance*. They adopted literature from different content areas, such as reading, for the science workshop context. In this paper, we use the same approach, but in the context of a STEM-focused summer camp that leverages Minecraft as the primary learning environment.

Our study is a contribution to the examination of interest triggers within a digital learning environment, a field of research still in its early stages. We utilize the popular video game, Minecraft, for participants to explore, to make observations, and to ask questions about hypothetical versions of Earth customized by our laboratory (refer to Yi et al., 2018; Yi et al., 2020). Minecraft provides an ideal space for our work because of the variety of science concepts that can be conveyed through the game, as well as being a space to collect data and conduct research on how gameplay reflects interest (Lane et al., 2017).

Methods

Participants were recruited from a local youth center for a five-day STEM-focused summer camp in 2020 (N = 7; 43% female; M = 12 years old). The majority of participants self-identified as African American (4) while others identified as biracial (2) and White or Caucasian (1). Due to the pandemic, we adapted our usual face-to-face intervention to a hybrid form of staff and participants attending in-person and the research team attending remotely. One-on-one interviews were conducted in a separate Zoom breakout room on the last day of the intervention. The interview protocol for middle school students consisted of 16 questions and covered topics on home and school life, long-term interest, Minecraft play preferences, astronomy knowledge, and camp feedback.

Analysis

Two researchers sectioned interview data into STEM interest triggering episodes, using the *unknown* label for codes that did not fall under the coding scheme. *Unknown* interest triggering episodes will undergo thematic analysis to create new codes or subcodes that wholly capture the out-of-school science learning experience. Each episode is distinguished by a particular interest topic. For example, when asked about engagements with science content, the interviewee may report how much they enjoyed their latest trip to a science museum, then relate the science museum experience to an enjoyable classroom lesson in the past.

Inter-rater Reliability (Cohen's Kappa)

In the identification of interest triggering episodes, there was a substantial agreement between the two researchers, $\kappa = .73$. All disagreements were resolved in conference. There was an almost perfect agreement between two researchers when using Renninger and Bachrach's coding scheme based on two interviews, κ = .94. All disagreements were resolved in conference.

Findings

Each STEM interest triggering episode was then coded using Renninger and Bachrach's (2015) scheme for interest triggers (see Table 1). Columns where interest triggers occurred are highlighted in orange.

Table 1: Interest trigger counts (in columns) based on Renninger and Bachrach (2015) codes

#	Auto-nomy	Chall-enge	Comp/ Tech	Group work	Hands-on activity	Instructional conversation	Novelty	Personal relevance	Unknown

Conclusions and implications

Our preliminary results show a prominent role for *personal relevance* which specifically relates to Minecraft use by using a familiar platform to build on prior knowledge, such as experiencing a difference in gravity (a previously learned concept) on the Moon. *Personal relevance* also relates through a desire to reengage in camp content—choosing our server instead of outdoor play during free time—and when expressing positive affect regarding future participation of camps. One advantage of using Minecraft is the capability of most learners to immediately engage the science content due to the game's relevancy and familiarity through previous play. Another reason for the high frequency of personal relevance triggering episodes may be related to the design and structure of our intervention that evokes feelings of personal relevance within the activities.

There were several interest triggering codes without any instances (i.e., *autonomy, challenge, computers/technology, group work, hands-on activity*). This may be due to the wording of our interview questions and/or the structure of our camp. Another possible reason is that we followed Renninger and Bachrach's coding scheme strictly and only allowed one type of code per episode. Future research designs using the coding scheme by Renninger and Bachrach (2015) should consider the use of multiple codes per episode.

Proof of Concept: Applying Recurrence Quantification Analysis to Model Fluency in a Math Embodied Design

Abstract: We report a subset of results from an exploratory study that modeled mathematics learning using a dynamical systems lens. This study applied Recurrence Quantification Analysis to model participants' interactions with a touchscreen-based embodied-design learning environment for proportionality, conducting both qualitative (case study) and quantitative (linear regression) analyses. Findings indicate an abrupt change in the RQA meanline metric associated with increased fluency, suggesting a phase transition into a new mode of interaction. These findings suggest theoretical and methodological traction for modeling embodied math learning as phase transitions in a human–technology dynamical system.

Dynamical systems theory (DST) approaches suggest that the complex interactions within and between body and environment shape cognition (e.g. Kelso, 1995; Richardson & Chemero, 2014; Thelen & Smith, 1994). How might a DST approach apply to higher-order cognition such as mathematics learning? We explored this question using a DST tool, *Recurrence Quantification Analysis (RQA),* on touchscreen data from a mathematics learning task. RQA begins with the construction of a recurrence plot, a way to map the alignment in states between two time series (Marwan et al., 2007) (Figure 1). RQA metrics quantify features of the recurrence plot. Our analysis explored five RQA metrics, but here, in the interest of space, we will present only the meanline metric. Meanline is the average length of diagonal lines on the plot. It reflects the level of predictability and stability of a system. Meanline trends are representative of those found across a panel of RQA metrics.

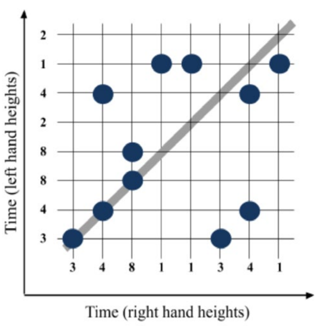

Figure 1. Example RQA plot for mock data of left and right hand heights (scale: 1-10 centimeters). Every position of each hand is compared to every position of the other hand. Aligned states are marked with a point.

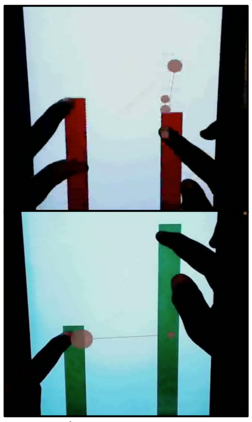

Figure 2. User interacting with the MIT-P. Upper image: bars are red. Lower image: The height of the left bar is half that of the right; bars turn green.

We conducted a secondary analysis of touchscreen and video data of students learning in an embodied-design environment (Abrahamson et al., 2020): the Mathematics Imagery Trainer Parallel Bars problem (MIT-P) (Figure 2). In this task, participants manipulated red bars on a touchscreen with the goal of turning the bars green and maintaining them green while moving them. The bars were set to turn green only when the ratio of the left to right bar was 1:2; moving-in-green required participants to move the right bar at twice the rate of the left. This movement problem was designed to ground concepts from proportional reasoning.

Our research question was: How does the predictability of hand coordination dynamics evolve as fluency increases in a math embodied-design learning task? To answer this, we conducted continuous cross-RQA of bimanual touchscreen data. We: (1) used linear regression to compare changes in meanline over time across all participants; and (2) analyzed the evolution of the meanline RQA metric for a pair of contrasting participants, one of whom reached fluency ("Nils") and the other of whom did not ("Liam"). For the regression analysis, we split each participants' time series into three phases—Exploration, Discovery, and Fluency—and regressed meanline on phase. We defined the onset of Discovery as when participants sustained green feedback above 50% of the time for 20 seconds, and of Fluency as when learners moved both hands at the same time in green at 80% of their personal best.

Regression results showed no statistically significant change from Exploration to Discovery. From Discovery to Fluency, meanline increased by an estimate mean of 14.8 deciseconds ($t=3.01$, $d.f.=85$, $p=0.003$), reaching about double the estimated meanline length of 15.63 deciseconds during the initial Exploration phase.

Examining the contrasting case studies (Figure 3), Nils' (reached fluency) meanline dynamics mirrored that of the overall group with longer meanline in the Fluency phase. His meanline increased abruptly synchronously with the onset of fluent moving-together-in-green (between the second dotted line and the second filled line in Figure 3, left) just after he articulated aloud an arithmetic rule to "make half" with his hands, identifying a multiplicative relation. In contrast, Liam's (did not reach fluency) meanline actually decreased over the course of the task. He, too, articulated a rule aloud, to "keep the right hand higher." Liam's qualitative rule did not yet appear to offer him as strong of a grip on the problem as with Nils: Liam did not manifest increased coordination fluency, nor an increase in meanline.

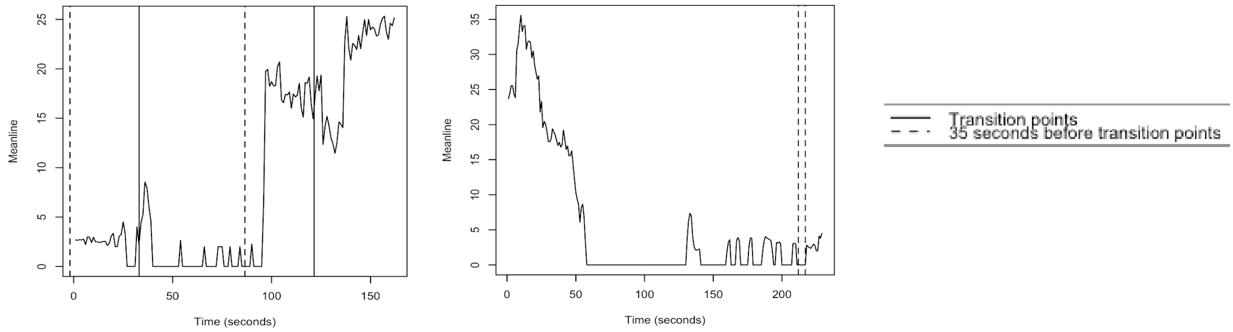

Figure 3. Windowed recurrence plots of meanline over time for Nils and Liam.

We found Fluency but not Discovery to be associated with increases in the RQA meanline metric, such that stability and predictability dynamics transformed when enacting moving-together-in-green. In the case study of a learner who attained fluency, meanline analysis showed an abrupt qualitative change. This finding evokes the dynamical-systems-theory phenomenon of a *phase transition*, whereby a system abruptly shifts from one state to another, such as from liquid to gaseous state of water. Our results suggest that the onset of fluent movement in the embodied learning of math content might constitute a phase transition in the learner–technology system. To the extent that we view higher-order cognitive activity, such as mathematical reasoning, as emerging from recurrent patterns of perceptually guided motor action (Varela et al., 1991), the Mathematics Imagery Trainer appears to constitute a *field of promoted action* (Reed & Bril, 1996) geared to foster transition into a new conceptually-salient ways of moving.

This study illustrates the traction of RQA on embodied learning data. RQA is apt for dynamical systems analyses, because it does not carry the assumption of linearity inherent in traditional quantitative methods, nor does it treat variability as noise. This proof-of-concept suggests that RQA can serve to characterize and potentially predict key moments of transition in learning. More broadly, RQA shows promise for studying the evolution of embodied-interaction learning dynamics as they unfold in time.

Florida State University

Abstract: We explored the representational flexibility development of adolescents with autism spectrum disorder (ASD) during VR-based simulation design and problem solving. We collected behavioral data of three adolescents with ASD from ten one-hour VR-based flexibility training sessions. The results of sequential data mining indicate that adolescents with ASD experienced different difficulties with representational flexibility during VR-based design problem solving. The study findings suggest that promoting the performance of attention switching and alternative representation tends to foster the performance of other representational flexibility processes.

Introduction

Representational flexibility is individuals' ability to flexibly switch attention between tasks, as well as identify and exploit various uses of representations (Rau, 2017). Recent research has studied the VR-based learning environment that engages adolescents with ASD in creative design and problem solving (Author, 2016). Despite the reported benefits of the VR-based training for adolescents with ASD (Didehbani et al., 2016), the 3D VR learning space tends to be visually-overwhelming and open-ended, and may create distraction and cognitive overload. It is critical to track students' competency development to provide learning supports adaptively and dynamically. However, there is a lack of empirical research that tracks the performance and development of representational flexibility in a digital learning setting. Using sequence mining, we aim to study the representational flexibility development of adolescents with ASD during VR-based design problem solving. Specifically, the study addressed the following research question: How did the representational flexibility performance of adolescents with ASD portray during VR-based design problem solving?

Method

VR-based flexibility training and data collection

Using Opensimulator—an open-source VR platform, we implemented ten VR-based flexibility training sessions that engaged adolescents with ASD in 3D scientific simulation design and encoding. Three adolescents with ASD (Average: 13.3 years old, SD = 1.24) attended nine 1-1.5-hour sessions during the training. In this study, the intervention task examined is developing computerized, non-player characters (NPCs or virtual agents). An NPC is a virtual character that conveys predetermined responsive or reactive behaviors. The adolescents with ASD needed to prototype the logics of computer scripts to encode NPCs that perform simplistic social interactions. During the NPC design task, the participants got to choose a preferred NPC simulation context (e.g., a cafeteria and a hotel reception) and designed an NPC tailored to the simulation context. An embedded scaffolding feature for representational flexibility is a 3D flow maker that assists participants in conceptualizing, visualizing, and designing the pathways of NPC interactions. Two facilitators observed and provided technical support as needed at every training session. For the data collection in the current study, we sampled the adolescents' computer logs that recorded their interaction behaviors with the 3D flow maker in all intervention sessions.

Data analysis

We conducted sequence mining procedures: (1) sequential pattern mining (SPM) and (2) sequential analysis. First, based on the collected computer logs, we implemented SPM to compute each individual's frequent behavior patterns, indicating how their performance of representational flexibility appeared (algorithm = SPAM, minimum support = 0.6). Using pre-defined behavior codes (Moon, Ke, & Sokolikj, 2020), we coded all behavior event transitions as either positive or negative occurrences related to the component facets of representational flexibility. Table 1 outlines the definition of each component facet of representational flexibility. Using the extracted sequences from SPM, we then conducted sequential analysis to identify how the adolescents' performance or states of representational flexibility (RF) changed during training. We calculated the transition probabilities of the RF states (cut-off probability: 30%).

Table 1: Component facets of representational flexibility (RF)

Facets of RF	Definition
Attention Switching / Mental set-shifting (AS)	Ability to switch attention or action based on changed rules and contextual demands
Alternative Representation (AR)	Capability to identify and apply multiple representations
Pattern Development (PD)	Ability to identify and delineate a pattern (or rules) during design problem analysis and solving
Pattern Contextualization (PC)	Ability to either identify an implementation context of the endorsed pattern or customize the pattern.

Findings

Using SPM, we identified the study participants' states of RF. As shown in Figure 1-a, all three adolescents with ASD generally increased the performance of attention switching and pattern development during the training. On the other hand, both participants A and B showed higher negative portrayals of attention switching and pattern contextualization; participant C showed worse performance in alternative representation.

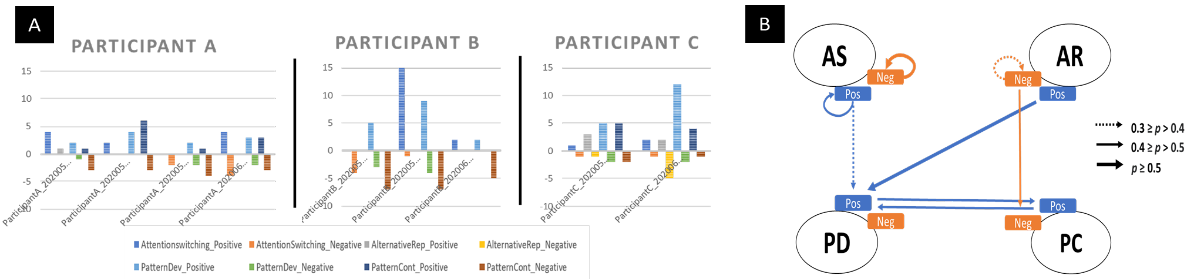

Figure 1. Competency development states of the study participants in the VR-based training (a) / Transition probability estimation of the competency states (b)

In addition, we calculated the transition probabilities of representational flexibility in terms of the four component facets. The transition probability estimation result confirms that adolescents with ASD were likely to show the iterative and unsuccessful performance of attention switching and alternative representations (Figure 1-b). On the other hand, if they performed successfully in attention switching and alternative representations, they had more chances to perform pattern development and pattern contextualization successfully.

Implication and limitation

The study findings indicate that adolescents with ASD experienced different difficulties with representational flexibility during VR-based design problem solving. It is necessary to present learner-adaptive, individualized supports in the VR-based learning environment. Promoting and scaffolding participants' performance of both attention switching and alternative representation will potentially promote the performance of other representational flexibility processes.

Engagement in MOOCs Discussion Forums: Dimensions and Indicators

Yannick Stéphane Nleme Ze, Gaëlle Molinari
Yannick.Nlemeze@unige.ch, Gaelle.Molinari@unige.ch
TECFA-University of Geneva and UniDistance

Abstract: This poster aims to clarify the notion of engagement in MOOCs discussion forums as perceived by students. The analysis of the 11 semi-structured interviews conducted with MOOC students highlights three main findings. First, engagement in MOOCs forums as a construct with four dimensions (behavioral, affective, cognitive and social). Secondly, a clear distinction between these dimensions using the related indicators we identified. Finally, the dynamic aspect of engagement. These results provide a socially and contextually grounded definition of engagement in MOOCs forums. That ensures the development of reliable and essential tools for measuring it and observing its quality over time.

Background and issues of the project

This study is part of a larger project that focuses on the concept of students' engagement in the context of discussion forums in MOOCs (Massive Open Online Courses). Our interest in this topic is supported by several studies, which show that students who frequently interact with others in forums are those who are the most successful in MOOCs (e.g., Poellhuber & al., 2019). Thus, we assume that by encouraging students' engagement in MOOCs forums, it would be possible to improve completion rates, which vary between 5 and 10%. However, engagement is studied mainly as a general phenomenon in distance learning and MOOCs (Molinari & al., 2016) and there is still little knowledge of the specificity of engagement in MOOCs forums, which are characterized by low interactions and participation rates reaching 3% (Margaryan & al., 2015). Moreover, research focused only on a few forms of engagement such as behavioral engagement, generally with indicators that are not commonly shared by researchers. It is, therefore, necessary to define more clearly, what it means to be engaged and disengaged in a MOOC forum, to identify the different dimensions of engagement and associated indicators.

Theoretical framework

We refer to the work of Fredricks & al. (2016) who define engagement as a construct with four interdependent dimensions, influenced by the students' perceptions of themselves and their learning environment. First, the behavioral dimension refers to the directly observable manifestations of learners' engagement in terms of participation, presence of positive behavior and absence of disruptive behavior during learning activities. Behavioral indicators of engagement in MOOCs forums may be the number of questions and answers posted (Onah & al., 2014). Cognitive engagement is a dimension that refers to the quality of the learning processes and strategies that learners implement. This dimension can be assessed based on the use of learning and self-regulatory strategies and also on the mental time and effort to implement these strategies. In MOOCs forums, the use of management strategies such as justifying answers to questions with relevant resources have been widely used as indicators of cognitive engagement (Quentin & Condé, 2016). Third, we have affective engagement that refers to interest and value placed on learning tasks as well as to positive and negative emotions experienced when completing them. Research mainly used positive (e.g., altruism for Cheng, 2014) and negative emotions as indicators to explore emotional engagement in MOOCs. There are still few studies that focus on such type of engagement in MOOCs forums. Fourth, social engagement is the last dimension studied by Fredricks and colleagues. Based on Molinari & al. (2016), we assume that students are socially engaged when they jointly try to both maintain positive interpersonal relationships and build upon each other's contributions in a MOOC forum.

Method and data analysis

Based on this theoretical framework, our aim was to investigate the dimensions and indicators of students' engagement in MOOCs forums. To that end, we carried out 11 semi-structured individual interviews (45-60 minutes) with certified students of the MOOC "*Introduction aux droits de l'Homme"* proposed by the University of Geneva on Coursera. Participants, who volunteered to be part of our study, were gradually invited to take part in the interviews until we judged that (1) new participants would no longer add significant new data to the description of the studied phenomenon (theoretical saturation) and that (2) the topics obtained offered a sufficient explanatory framework with regard to the data collected (theoretical sufficiency). Only men agreed to participate in these in-depth interviews. An interview guide was developed based on that one used in Fredricks & al. (2016) and contained the following questions: (1) what does it mean for you to be engaged and disengaged in a MOOC forum?; (2) what do students do when they are engaged and disengaged in a forum?; (3) In your opinion, what influences engagement and disengagement in a forum? In the present paper, we report on the answers to the first two questions. There were two main steps in the analysis. First, we have appropriated the content of the answers by replaying the audio recordings, retaining the richest interviews, transcribing the selected interviews, choosing the units of analysis and drawing up a provisional coding manual. Second, the transcripts were coded and the codes were grouped into categories anchored in the conceptual framework of engagement and, finally, the results were interpreted. The results are the perceptions of adult respondents (8/11 over the age of 30) from 10 countries, postsecondary level and living in urban African (6/11), Latin American (3/11) and Haitian (2/11) areas.

Results and future work

The results show that indicators used by students to conceptualize engagement in MOOCs forums may be categorized into the four dimensions identified in the theoretical framework: behavioral, cognitive, affective and social. Behavioral indicators (e.g., asking questions and answering to questions from others; providing others with quick answers) allow for direct observations of engagement because they correspond to the traces left by students in the forums. Then, emotional indicators (e.g., being happy to participate in a forum; being interested in the topics of the discussions) relates to the interest and value placed by students on the forum discussions as well as the emotional intensity of the discussions. Besides this, three types of cognitive indicators are proposed. The first type refers to the use of learning strategies, in particular to organization and elaboration strategies (e.g., synthesizing discussions; arguing and clarifying answers to questions) while the second type refers to self-regulatory strategies including metacognitive (e.g., trying to understand one's mistakes during exchanges) and management strategies (e.g., doing further research on the topic addressed by the posted question). The third type of indicators refers to time needed to implement those cognitive strategies (e.g., dedicating enough time to participate in forum). Finally, social engagement is described, on the one hand, by relational indicators (e.g. commenting on the others' ideas and opinions with respect and empathy) in order to maintain positive relationships in discussion forums. On the other hand, by socio-cognitive indicators (e.g., combining one's own ideas with those of others to answer questions that seem difficult) related to the students' attempt to engage in high transactive social modes.

What about disengagement? Disengagement is described by indicators reflecting a lack of engagement at the behavioral (e.g., not asking and even answering questions), cognitive (e.g., not using the forum to understand a concept) and social (e.g., not discussing ideas with others, not helping others solve problems) levels. Students also provided indicators related to low quality or low level of engagement such as allocating little time to participation in the forum discussions, answering in a superficial way to questions, answering questions without seeking more information about the topic at hand or making comments that may offend the others. Moreover, emotions expressed to describe disengagement (e.g., fear, disinterest, dissatisfaction, frustration) are opposed to those given for emotional engagement. All these results suggest that engagement in MOOC forums is a dynamic phenomenon, as it can be absent, low or high among students, and also can fluctuate throughout the discussions.

In our future work, we will use the indicators we have identified to develop an assessment tool able to measure the fluctuation of students' engagement in MOOCs forums. We will also identify factors that may explain this fluctuation. Our project's results will help to identify those students who are most likely to disengage from MOOCs forums activities and to design more targeted pedagogical interventions to strengthen their engagement.

Exploring Self-Efficacy Shifts within an Informal STEM Program

Areej Mawasi, Arizona State University, amwassi@asu.edu
Ruth Wylie, Arizona State University, ruth.wylie@asu.edu
Peter Nagy, Arizona State University, pnagy1@asu.edu

Abstract: Engaging in informal learning activities can support non-dominant learners' identity development, agency, and interest in STEM. In this paper, we build on the potential of community-based settings in engaging non-dominant learners (n=10) to explore learners' science self-efficacy. We find that overall self-efficacy improved, but not all students followed a similar learning trajectory. We explore these differences using examples from interviews and close by discussing methodological suggestions to address such emerging differences.

Introduction

In this poster, we build on previous work that demonstrates the potential for informal learning activities to create equity-oriented learning spaces and pedagogy that support non-dominant learners in STEM fields (e.g., Barton & Tan, 2010; Pinkard et al., 2017). Here, we attempt to identify methods for understanding shifts in science self-efficacy within the context of Palestinian learners' engagement in an out-of-school community-based program in Israel. Understanding learners' science self-efficacy within this context is important for both practical and theoretical reasons. Historically, Palestinians in Israel have been experiencing a systematic marginalization, rooted in settler-colonial citizenship dynamics within this political context (Rouhana & Sabbagh-Khoury, 2015). On a practical pedagogical level, cultivating self-efficacy is a major motivation of our collaborators at Al-Rowad for Science and Technology working with Palestinian Arab learners from their society in Israel. Understanding the role of context expands our methodological tools towards applied research with local communities and is a generative way of engaging with local communities (e.g., Medin & Bang, 2014). At a theoretical level, self-efficacy is defined as the belief that one is capable of taking part in an action or an activity at a designated level affecting learners' perceptions of their capability to complete a task (Bandura, 1997). Measuring self-efficacy towards science with careful attention to the context in which activities are situated can give an understanding of the complexity of such effects. Here we ask: Does science self-efficacy shift after engaging in an out-of-school, community-based program? If so, how?

Activities

This study is part of a larger project that aims to better understand the engagement and participation of learners within a community-based organization's transdisciplinary STEM learning program. This paper explores science self-efficacy shifts after students participated in the 4-day program (8 hours total). The program consisted of four major transdisciplinary hands-on activities designed by the organization: *Super Absorbent Polymer (SAP),* where learners were introduced to concepts and phenomena like colors and diffusion; *Newton's Disc,* which focused on light, color, and mechanical motion; *Illuminating Board,* where learners explore characteristics of light, dark, and illuminating materials in objects and animals; and *Oil & Water,* where students were exposed to volcanism, density, and reactions between substances. These activities were transdisciplinary by design. For example, each activity involved an artistic element, providing opportunities for transdisciplinary learning (Mawasi et al., 2021).

Methodology

Ten fifth- and sixth-grade learners (five girls, five boys) participated in the program. All participants are Arabic-speaking and attended all four days of the program. We used a pre-post learner questionnaire that included questions about learners' science interests, technology engagement in general, and science self-efficacy. The pre-post questionnaires were translated to Academic Arabic. After the program activities were completed, we conducted semi-structured interviews, where we asked them to elaborate on selected items from the questionnaires. Importantly, learners were not asked to explain why they chose the answer on the posttest. Instead, they were asked the question anew, encouraging them to answer based on how they were thinking at that moment.

Findings

Overall, we find a trend towards learners' science self-efficacy improving from pretest ($M=3.2$, $SD=.36$) to posttest ($M=3.5$, $SD=.38$), ($t(9)=-2.15$, $p=.06$). However, when looking at the items separately, we see that this trend is driven by a single item: "I can use science to solve problems in everyday life" (Pretest $M=2.6$ ($SD=.97$), Posttest $M=3.6$($SD=.52$), ($t(9)=-3.0$, $p=.015$). We observed that learners' answers shifted between the posttest and interview, with interview answers more closely aligning to responses given on the pretest. We use the qualitative data to explore how students are describe these concepts in order to better explain these findings. An inductive analysis (Thomas, 2006) allowed an understanding the ways of thinking that mediate learners' responses. Stances were interpreted and analyzed by the first author, who is from the local community (fluent in both Academic Arabic and Palestinian Arabic) and studying in the United States. The first author then created codes in English, and the stances that reflected codes were translated to English. Then the first author and second author (from the United States) discussed the codes. A major theme we identified is that there is neither internal nor external consistency in the way that students operationalize the term *science*. By external consistency, we mean that within an item, some students used the term to mean the school subject, whereas others took a more holistic approach. By lack of internal consistency, we mean that individual students changed the way they defined the term between questions (e.g., for the item "I can learn science easily," a student might have described doing well in science class, but for the item, "I can use science to solve problems in everyday life," a student might describe a scientific phenomenon that occurs at home). Results from the interviews reflect that learners demonstrated diverse ways of contextualizing science. For each item, the learners referred to either school, the program, everyday life, or general science, or a combination of these.

Discussion and implications

The findings reflect descriptive shifts in students' self-efficacy; however, these shifts were driven by a single item. Yet, the interviews show various ways of conceptualizing science across items. We explain these variations through the diverse ways students reflected on their engagement, including attending to knowledge they learned (procedural and declarative), describing how they used the activities at home, and perceived self-efficacy in relation to the physical artifacts they created. These results reflect that some learners' perceptions of what counts as science connects to their conception of doing well in school science. We also see that it is important to revisit the methodological tools applied within this local context. First, to be linguistically open, to expand ways for students to express their thinking and learning process (e.g., being prepared to use both Academic and spoken Palestinian Arabic, diverse use of dialects). Second, it is also important for the process of creating and iterating on assessments to understand learners' perceptions of learning and the teacher's role, as well as the various ways that learners perceive artifacts, and the social and political context mediating learning activities. Finally, it is important to be open to involve, share, and discuss results and design with community members throughout the process. We believe that collaborating with local community members to develop measurements, rather than relying solely on dominant scientific instruments that do not account for context, will deepen our understanding of learning.

Expanding Science Learning within Community-Based Hands-on Transdisciplinary STEAM Experiences

Areej Mawasi, Arizona State University, amwassi@asu.edu
Ruth Wylie, Arizona State University, ruth.wylie@asu.edu
Punya Mishra, Arizona State University, punya.mishra@asu.edu

Abstract: In this paper, we examine how a four-day out-of-school program planned and taught by a community-based organization allowed for a range of educational possibilities, specifically unlearning "school science" by participating in transdisciplinary STEAM activities, which in turn, offered generative ways to develop STEAM-related identities. These outcomes enabled learners to expand the ways they view science learning. Implications of this experience for designing and studying learning experiences for non-dominant learners are shared.

Transdisciplinarity: Thinking beyond disciplines to engage non-dominant learners in informal STEAM activities

Transdisciplinarity allows learners to creatively connect "different solutions, viewpoints, or perspectives" across disciplines (p. 24, Mishra et al., 2011). In the past decade, education research has stressed the importance of developing transdisciplinary STEAM curricula that encourage learners to view science, technology, engineering, and math as interconnected and to think critically and ethically about STEM disciplinary practices (e.g., Rosebery et al., 2010; Takeuchi et al., 2020; Mishra et al., 2011). In STEAM environments designed for non-dominant and historically marginalized learners, transdisciplinarity allows educators to leverage learners' assets (e.g., using culturally-relevant artifacts or linguistic resources) and diverse range of identities (Gee & Parekh, 2018; Nasir et al., 2006) to expand learning possibilities beyond the constraints of one specific discipline (Takeuchi et al., 2020). Such equity-oriented approaches allow for diverse forms of engagement and participation within learning environments. This allows learners to forge connections between learning environments that are both in and out of schools, connect knowledge across disciplines, and connect their learning activities to their identities, therefore linking these fields to their lived experiences (Sengupta-Irving & Vossoughi, 2019).

These opportunities are particularly relevant for the work that our collaborators, Al-Rowad for Science and Technology, do with Palestinian youth in Israel, a non-dominant population in STEAM and a historically marginalized population. While framing their work as "Science and Technology," the organization aims to increase individual and societal self-efficacy towards science by intentionally engaging learners with transdisciplinary hands-on activities that connect science, technology, engineering, art, and math.

Learning environment context at Al-Rowad for science and technology

We collected data from a four-day program for 10 fifth- and sixth-grade learners, led by two educators from the organization. Each day focused on a different concept and included didactic teaching, discussions, and hands-on activities. The instruction was often structured as a series of questions that prompted students to connect science concepts to everyday phenomena. The lead teacher would emphasize that "there is no right or wrong answer" to encourage students to share their thoughts. She respected learners' choice to not participate in the discussion, acknowledging that some students have different preferences about sharing in large groups. After these discussions, learners were given hands-on toolkits and instructions to build and complete the day's hands-on activity artifact. Students were then encouraged to take the completed activity home to share with family. In total students completed four activities: Super Absorbent Polymer, Newton's Disc, Illuminating Board, and Oil & Water.

Methodology for data collection and analysis

The data for this paper comes from a series of semi-structured interviews with participants (n=10) following the four-day (8 hour) workshop. The interviews were 40-60 minutes long (average time = 48.4 min, SD=8.9 min). An initial inductive coding was followed by a close reading of the interviews, first cycle coding of interviews, and writing summative memos about each student's experience (Saldaña, 2015).

Findings

Although the program was centered on scientific issues and promoted as focusing on science, participants engaged in activities that crossed disciplinary boundaries. This engagement and participation allowed learners to expand their knowledge of STEAM possibilities (i.e., STEAM practices as interconnected and connected to varied disciplines). For instance, these activities included not just working and playing with colors and lights, but also processes of thinking, planning, drawing, and prototyping that unite the arts, science, and engineering. This transdisciplinary approach provides an alternative to traditional modes of school science and thereby expands what counts as authentic science, pushing participants to *unlearn school science* as reflected through the students' perceptions.

Since the hands-on activities incorporated *a transdisciplinary* connection between science, technology, and arts, this allowed learners to build multiple hands-on tools which serve as modeling for phenomena they discussed in class. On the other hand, not all learners described the activities as transdisciplinary. Examples in interviews indicate that STEAM learning is an emergent transdisciplinary process. While learners, in some cases, did not necessarily identify certain practices as tied with specific disciplines, they were attempting to think about STEAM through their own identities (e.g., I imagine, I draw) or activities they themselves do (e.g., drawing, playing with family). While at a surface level, it might read as if learners are not engaged in talking about STEAM disciplinary practices or discourses, it can be an opportunity for expanding ways in which non-dominant learners enact STEAM in relation to their everyday lives and self-identities. We expand on this idea of emergent identities below.

We identified varieties in how students perceive their STEAM activities, practices, and roles. These varieties reflect how each student's unique learning trajectory may be shaping their perceptions of engagement and participation within the program. The unique ways learners expressed their thinking enabled us to identify *emergent identities* in relation to the students experiences with activities. For instance, a student perceiving an artifact as an art, enabled them to see themselves as an artist and build connections between art and science.

Summary

The program activities that these learners participated in align with Dewey's (1956) fourfold areas of interest for learning: "the interest in conversation, or communication; in inquiry, or finding out things; in making things, or construction; and in artistic expression" (p. 48). Through these activities, learners engaged in (a) conversations and communication about STEAM practices both within and outside the program's in-person activities; (b) observation and inquiry; (c) making and constructing artifacts with scaffolds provided by instructors; and finally, (d) artistic expression through working with colors, drawing, and the aesthetics of the final artifact.

Looking beyond the specifics of this project, we suggest enabling a space for learners to expand agency towards the ways they see, engage, and perceive science activities, by viewing STEAM learning as an emergent process, rather than a process with science learning as its sole outcome. It is through the thoughtful design of pedagogy and activities that learners can go beyond seeing science as a disconnected array of facts taught in school, and instead approach it as an organic body of knowledge that is connected with other disciplines and with their personal lives and identities.

Promoting Science Self-Concept with Inquiry-based Curricula

Mike Stieff, Stephanie M. Werner
mstieff@uic.edu, swerne3@uic.edu
University of Illinois, Chicago

Abstract: Science self-concept is a strong predictor of engagement in science learning and career choice. Students who report higher science self-concept display more self-efficacy and greater achievement in their science courses, which positions the construct as a potential target of curriculum interventions. Here, we report our interim findings regarding the potential of a technology-infused guided-inquiry curriculum, The Connected Chemistry Curriculum, for improving students' chemistry self-concept. Using data from a longitudinal study of the curriculum's efficacy, we analyzed improvements in 1048 students' chemistry self-concept after using Connected Chemistry for an academic year. The results show that CCC significantly improves students' chemistry self-concept compared to business-as-usual practices.

Keywords: Self-concept, Inquiry, Science Education

Introduction

The Connected Chemistry Curriculum (CCC, Stieff, Nighelli, Yip, Ryan, & Berry, 2012), a technology-infused guided inquiry curriculum, is a self-contained chemistry curriculum that makes central use of visualization software to facilitate learning in secondary chemistry. Like other science curricula that emphasize the use of educational technologies (e.g., SimCalc, PhET), CCC aspires to serve the dual purpose of supporting learning while providing youth with an opportunity to increase their experience and proficiency with digital mediums. The curriculum has been under iterative development for 18 years, and studies of CCC have focused mainly on its efficacy for improving conceptual change and representational competence in the discipline. Here, we report our initial efforts to examine the potential of the curriculum to impact socio-affective factors, such as self-concept.

Present study

We present here our preliminary analysis of the long-term impact of a 9-month implementation of CCC on self-concept. We conducted an implementation study that compared changes in students' self-concept in chemistry, math, and general academics in classes taught by the same group of teachers with or without implementing CCC. Specifically, we tested whether students in CCC classes reported higher levels of chemistry self-concept.

Study context

The data reported on here were collected during 2017-2019 in the context of an ongoing efficacy study of CCC. Participating schools were located in one of three urban/urban-fringe school districts in the U.S. Great Lakes region. 31 participating teachers taught chemistry with business-as-usual (BAU) methods for one year before implementing CCC in the consecutive year. An implementation of CCC consisted of implementing a minimum of one lesson from each of CCC's 9 curriculum modules throughout the year. In both years, research personnel made visits to the participating classrooms approximately once per month to collect field observations, collect data on fidelity of implementation, and administer pre- and post- measures to students.

Instrument

Self-concept was assessed with The Chemistry Self-Concept Inventory (Bauer, 2005), a measure for assessing self-concept related to chemistry, mathematics, and academics. The 40-item Likert survey assesses students' self-concept of themselves as learners and includes 5 subscales: chemistry learning, mathematics learning, academics in general, academic enjoyment, and creativity.

Participants

2366 students taught by 31 teachers completed the self-concept inventory at the beginning and end of each school year. The survey was administered in class within the first two weeks and last two weeks of each school year.

Results

Before analyzing the effect of the CCC implementation, we tested the validity and reliability of the survey in this study. 1301 completed surveys administered during the first two weeks of the BAU data were sequestered for this analysis. Four of the five subscales had good reliability (Chronbach's $\alpha > .72$). Via Confirmatory Factor Analysis, we found that a four-factor model with the Creativity subscale ($\alpha = .44$) removed best fit the data, ($X^2(521) = 3568.528$, $p < .001$, CFI = .81, RMSEA = .067).

We constructed a multilevel model (MLM) to determine the effect of CCC implementation (BAU vs. implementation) on student self-concept (gain scores). For this analysis, only students who completed 100% of all pre- and post-test survey items were included, which resulted in 1048 students. Individual students were nested within their teacher for this analysis. All subscales were normally distributed based on visual inspection of the histograms. For most of the subscale pairs, there was a general linear trend as shown by a scatterplot matrix. There was no multicollinearity between the dependent variables, with all Pearson correlations below $r = .41$, $p < .05$. Levene's test for homogeneity showed that one subscale, chemistry, did not meet this assumption, $F(1,1046) = 6.284$, $p = .012$. A MLM was run for each of the four dependent variables (subscales) with students nested within teacher. Only one model had significant fit: chemistry self-concept ($F(1,1039.813) = 35.275$, $p < .001$). All other models were nonsignificant (Table 1). For the significant model, a statistically significant difference was found between BAU and CCC Implementation Years (B = -.2642, SE = .0445, $p = .001$). Upon implementing CCC, students within the same teacher improved their chemistry self-concept by a factor of .26.

Table 1: MLM fit statistics for each model.

Self-concept subscale	Model fit	B	SE	p
Chemistry	$F(1,1039.813) = 35.275$, $p < .001$	-.2642	.0445	.001
Math	$F(1,1042.718) = .200$, $p = .654$	-.016585	.0370	.654
Academic	$F(1,1043.552) = .058$, $p = .810$	-.008963	.0374	.810
Academic Enjoyment	$F(1,1046) = .260$, $p = .610$	-.0196	.0385	.610

Conclusions

Our results suggest that implementations of CCC can yield improvements in students' self-concept and that this improvement is specific to chemistry. We observed a significant improvement in chemistry self-concept in CCC classrooms relative to business-as-usual practices, but no concurrent improvements in other attitudinal factors. The specificity of this effect is consistent with other reports (e.g., Scherer, 2013) that have identified domain-specific aspects of science self-concept. Importantly, the specificity of the finding suggests that CCC works to improve students' science self-concept in classrooms where it is implemented but does not lead to general improvements in academic self-concept or enjoyment. Our interim findings lend empirical support to earlier predictions (Jansen, Scherer, & Schroeders, 2015) that inquiry curriculum can better develop students' science self-concept relative to other designs and suggest that self-concept may be an important target for future design-based research studies.

Towards a Theory of Mathematics Teacher Learning Ecologies

Nadav Ehrenfeld, Vanderbilt University, nadav.ehrenfeld@vanderbilt.edu

Abstract: Research on mathematics teachers' learning typically focuses on single activities or programs and does not acknowledge the interactive impacts of multiple experiences in different settings. In contrast, from a teacher perspective, teacher learning happens across time and settings, through a complex web of learning experiences. In this conceptual paper, I propose how we could extend interactionist approaches to include a systems-level lens, towards a theory of teacher learning ecologies.

Introduction and purpose

The main premise of this paper is that teacher learning happens across time, settings, and activities (Borko, 2004; Clarke & Hollingsworth, 2002; Horn et al., 2013). While these ideas are not new, they have not yet been worked into theories and designs for teacher learning. Consequently, as a field, we seldom study and design teacher learning across the multiple sites of its development. In a review of 106 research studies about mathematics teacher learning, Goldsmith et al. (2014) claimed that none of the studies "prospectively laid out an iterative, multidomain theory of action for the intervention" (Goldsmith et al., 2014, p. 20). This is a problem, because employing simplistic conceptualizations of teacher professional learning limits our ability to explain — and consequently to support — different paths for such learning (Clarke & Hollingsworth, 2002; Opfer & Pedder, 2011). With this discrepancy in mind, rather than describing a certain activity, or certain features of activity, as optimal for teacher learning, the goal of this study is to work towards a more holistic conceptualization that highlights possible relationships between learning processes, settings, and activities. My point is neither to diminish the value of research on the effects of specific activities (or certain features of activities) on teacher learning, nor to claim that every study of teacher learning must include all possible aspects of teachers' learning ecologies. Rather, I claim that (1) attempts to look at subsystems must be understood as partial (Opfer & Pedder, 2011) and (2) employing more complex theories of teacher professional learning would extend our ability to explain and consequently to support teachers (Clarke & Hollingsworth, 2002). The goal of this paper is to work toward such conceptualization.

Extending interactionist perspectives to include system-level analysis

Research on teacher learning in math education tends to focus on the effect of PD interventions, where learning itself is not the main object of study but rather an indicator of the effectiveness of specific curricula, programs, or features of activity (Goldsmith et al., 2014). Interactionist perspectives on teacher learning break out of these constraints and privilege context, complexity, interactions, and questions such as why, how, what, and under what conditions teachers learn. At the center of interactionist perspectives on teacher learning is the sociocultural notion that learning is social and talk plays a main role in learning processes (Horn & Bannister, 2020). Interactionist researchers operationalize learning in a variety of ways: They detect specific learning moments within meetings; follow processes of collaborative and individual meaning-making and knowledge construction; and underscore conditions that are productive for learning (Lefstein et al., 2020). More generally, learning is mostly seen through changes in discourse in the immediate PD setting. Less prominent in interactionist perspectives is explicit attention to accounts of learning that are distributed across settings as part of participation in a broad range of activities, more and less formally structured (for exceptions, see Ehrenfeld et al., 2020; Horn et al., 2013). For example, in their review, Lefstein et al. (2020) noted that researchers in this field rarely attend to broader contexts of teacher conversations; "rather, they primarily focus on the immediate context of the setting or intervention" (p. 6). Accordingly, I argue that studies that take an interactionist perspective of teacher learning typically make rich connections between learning and its immediate contexts, but pay less attention to connections among different settings and activities teachers participate in. My approach in this paper is to extend interactionist approaches to include system-level analysis. That is, I suggest that to fully realize the affordances of interactionist theories for teacher learning, we need stronger theoretical connections between different scales where such learning takes place (see Figure 1).

The claim that we need stronger theoretical connections between the immediate and larger contexts of teacher learning reflects more general calls in the Learning Sciences. One such example comes from the recently published Handbook of the Cultural Foundations of Learning, wherein Nasir et al. (2020) conceptualize learning as "occurring along culturally organized learning pathways—sequences of consequential participations and transitions in learning activities that move (or do not move) one towards greater social recognition as competent in particular learning domains and situations" (p. 195). Nasir et al. made the overall claim that focusing only on local learning interactions limits our understanding of the cultural, relational, affective, and contextual nature of learning and their intersections with systems of power. I build on this example and other system-level models for learning to start imagining directions for theorizing teacher learning ecologies. Specifically, I recognize different forms of system-level learning as possible directions of research that would potentially explicate mechanisms of learning across settings, where teachers' practices shift over time.

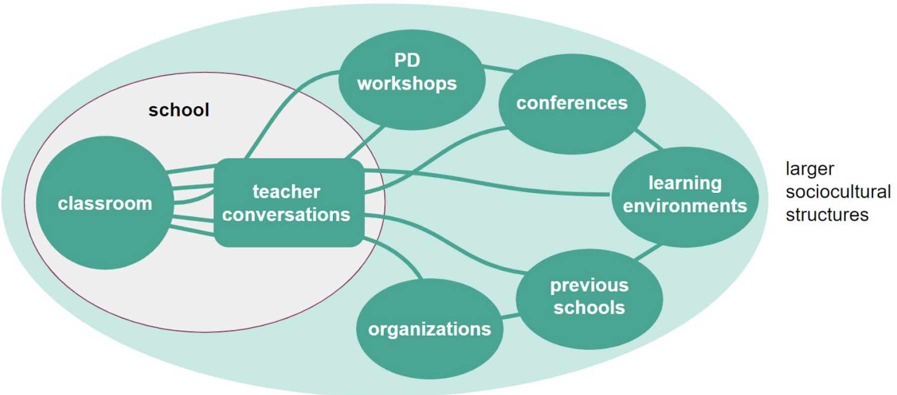

Figure 1. Suggested scope of an ecological perspective on teacher learning.

Significance

To support mathematics teachers, it is critical to understand how teachers learn across settings and to characterize the patterns of such processes (Borko, 2004; Horn et al., 2013; Opfer and Pedder, 2011). Interactional programs of research offer strong connections between learning and the immediate teaching context. Yet, these studies are typically bounded in specific activities and overlook broader learning contexts. I suggest extending interactional perspectives to encompass system-level analysis of learning. Such a perspective would open new spaces for thinking about, seeing, and designing for ecological teacher learning.

Embodied Discourse Analysis of Online Student Study Sessions: A Novel Method of Screen Recording Research

Anne Fensie, Asli Sezen-Barrie
anne.fensie@maine.edu, asli.sezenbarrie@maine.edu
University of Maine

Abstract: Understanding the experience of nontraditional learners in distance learning is important for course design and facilitation and may illuminate issues that contribute to high attrition rates. This study used a novel approach to capture and analyze the engagement and distractions of students as they participated in online classes. Students recorded their screens along with webcam and audio, and this data was analyzed using embodied discourse analysis. Findings suggest that mother-students were particularly challenged with balancing these two roles at home during the COVID-19 pandemic but redesigning the environment and utilizing self-regulated learning strategies may be beneficial.

Introduction and background

While participation of adult learners in distance education has steadily increased (MacDonald, 2018), the sudden expansion of remote learning due to the COVID-19 pandemic has made it especially important to understand the experience of students who are learning from home with all of the distractions that entails. Our research questions are, *1) How do we explore nontraditional students' engagement in online learning tasks by using embodied discourse analysis? 2) How can we identify distractions in the learning environments of nontraditional students that contributes to or are a barrier to their success?*

Student engagement and distraction: Discourse Analysis Approach

Researchers have conceptualized engagement in terms of observable student behaviors, emotions, cognitive dimensions like self-regulated learning, and academic aspects like time on task. A newer and related area of research in online learning is the study of distractions (Blasiman et al., 2018; Hollis & Was, 2016), which can be barriers for student engagement. Coding methods for identifying student engagement during in person class time are well-established (Kubany & Sloggett, 1973), but a consistent method does not yet exist for distance learning.

An embodied discourse analysis approach can be helpful in more fully understanding an event as this enables us to move beyond the surface actions of an event and see the more subtle and compelling power dynamics at play among the participants (Rowe, 2004). In our study, the discourse is the actions the students is taking, the discursive practice is the prosocial behaviors of the student that conform to instructor expectations, and the sociocultural practice is the home context where the practice of being a student intersects with the home life and other identities of the students.

Methods

Our collective case study included four academically high achieving working mothers who were all experienced in distance learning prior to the pandemic. Students were given unique *Zoom* links and instructed to share their screen, enable their webcam, and microphone to record ambient audio during study sessions. Interview transcripts were organized in *Dedoose*, a qualitative analysis software, and screencast annotations were organized in *Google Sheets*. Students' actions on the screen were annotated in a spreadsheet, including mouse movements on the screen, active windows, the gaze of the student, other movements captured on the webcam, and ambient audio in the room where the student was studying.

Data analysis and findings

We watched each recording in whole and in parts several times at various playback speeds, identifying the type of interaction (student action on the screen), tenor (level of distraction as evidenced by gaze and noises in the environment), and field (environment of the student and situation within the course) (Rogers, 2003). We made a separate spreadsheet for each study session using a template created in *Google Sheets*, which could easily be shared among the researchers, enabling multiple researchers to code the excerpts and determine inter-rater reliability. Each excerpt was described by the researchers with annotations. We used an inductive approach to develop process codes across participants (Charmaz, 1996). We labeled each excerpt objectively as either *undistracted* or *distracted*. For example, loud noises from a television were coded as *distracting*, whether or not the student was actually distracted by it.

We noticed that at times, the student worked through the distractions, so we also marked the level of engagement of the student: *continues working*, *stops working*, or *undetectable*. These two levels of coding helped to identify whether the loud noises from the environment were actually distracting the student. Each undistracted excerpt was coded for the type of learning activity in which the student was engaged: *reading*, *writing/creating*, *watching a video*, or *navigating/searching*. Each distraction was coded by the type of the distraction (*switching windows/scrolling*, *cell phone*, *social media*, *looking away from the screen*, *engaging with another person*, *walking away*, *drinking/eating*, *movement*, *talking*, *noise*, or *technology*) as well as the source of the distraction (*self*, *adult*, *child*, *animal*, or *other*). Codes were defined to ensure uniformity in application throughout the sessions analyzed.

The excerpts were sorted and totaled to determine total time spent being distracted, in recovery, or undistracted, as well as the percentage of the total time. Codes were totaled for each session and frequency of each was determined. Excerpts were grouped by distraction, learning activity, source, and engagement to determine correlations and triangulate with interview responses. This process allowed us to draw conclusions around the engagement-distraction interaction in each study session and synthesized as a whole.

Results showed that nearly half of the recorded study session time included distractions. Participants were able to work through varying amounts of distraction, mediated by the urgency of their children's needs, the interest in or relevance of the content to the learner, and the instructional design. For example, in an activity where learners were scaffolded over several lessons through the process of using financial reports to analyze familiar companies, the learners were able to persist through distractions, particularly when they read aloud or spoke to themselves about what they were doing. Students were also more actively engaged during generative activities versus more passive learning activities like reading or watching videos.

Contributions and limitations

The findings in this study have helped us to understand how working mothers participate in distance education. For the most part, students work in small chunks of time whenever they can, preferably in the least distracted location in their home. Children were the biggest source of distraction for these mother-students. Maintaining these two roles in the home environment was challenging for these participants. It will be important for further study to analyze the experience of caretakers of other genders as well as students without caretaking responsibilities to understand the student experience from an equity perspective. Students who struggle academically should be studied in this way to determine what level of distractions they face as this may be a determining factor in their lack of persistence. Results highlight the importance of considering the high level of distraction present in the home environment during distance learning. The close analysis used in this study provided important insights into the experience of nontraditional learners in distance education and further study using these methods of data collection and analysis can be beneficial in illuminating the challenges and strategies that students use.

Rethinking Technology-based Educational Studies in the Evolving Classroom Environment: An Interview Study with US Teachers

Tomohiro Nagashima, Gautam Yadav, Vincent Aleven
tnagashi@cs.cmu.edu, gyadav@andrew.cmu.edu, aleven@cs.cmu.edu
Carnegie Mellon University

Abstract: Despite the prevalence of conducting classroom studies using educational technology, it is underexplored what practical benefits classroom studies with educational technology offer to teachers and students, and what concerns or challenges they perceive. Our interviews found that teachers view study participation as a meaningful learning opportunity but also shared challenges and concerns, some of which are related to remote learning during the COVID-19 pandemic. We offer strategies that researchers can employ when conducting classroom studies.

Introduction

For decades, researchers of educational technologies have studied the effectiveness and use of educational technologies in the school classroom context (e.g., "in vivo" experiments, by Koedinger et al., 2009) to advance the science of learning. From a pragmatic viewpoint, however, it is essential that not only researchers benefit from classroom data collection but also that practitioners (i.e., teachers and students) find practical benefits in participating in research studies with educational technology (Coburn & Penuel, 2016), which has not been explored thoroughly in the literature.

Understanding practical benefits and associated challenges and concerns in participating in classroom research is even more important in times of crisis. In the year 2020, due to the spread of the coronavirus disease (COVID-19), a vast number of schools have been forced to make a transition to remote instruction to continue teaching and learning. It has significantly affected teachers and students in various ways, resulting in problems such as teachers' increased workload (Reich et al., 2020). Under such a drastic change to school environments, conducting classroom studies may cause additional stress and workload for teachers and students, who are already struggling with adjusting their practices. To explore how educational technology researchers can ensure that practitioners benefit from participating in classroom studies especially during the pandemic, we conducted interviews with US teachers, exploring *what practical benefits, challenges, and concerns teachers perceive for participating in classroom research in general and specific to the remote teaching setting.*

Method

We remotely interviewed seven middle- and high-school mathematics teachers in the US. We targeted teachers who either had expressed an interest in participating in classroom studies or had participated in a classroom study with us during the pandemic. Two graduate students analyzed approximately 11 hours of video-recorded data following an Affinity Diagramming approach. They generated a total of 179 codes and clustered into 70 mid-level themes, which were then grouped into eight major themes.

Results

Our analysis revealed eight major themes across two categories: perceived benefits and concerns/challenges in participating in classroom studies (Table 1). We discuss one theme from each category due to the page limit.

Table 1: Perceived benefits and concerns/challenges in participating in classroom studies

Benefits	**Concerns/challenges**
Teachers consider that students will benefit by meeting researchers *in the wild*	Teachers find it hard to know what level of interventions and facilitation is appropriate during studies
Teachers consider that students will be motivated to contribute to science	Teachers prefer customizability and flexibility regarding research participation and content to-be-covered
Teachers will have an opportunity to understand their students from a different perspective	Teachers are concerned with lack of synchronous, immediate support for remote students
Teachers view participating in educational research as professional development opportunity	Teachers are concerned with students' various learning environments during a pandemic

One benefit: students will benefit by meeting researchers *in the wild*

Teachers strongly emphasized the importance of connecting their students with researchers. Teachers view welcoming researchers in the classroom as an opportunity for students to learn about research as a real job (e.g., knowing what researchers do) and about opportunities that exist outside the classroom. One teacher stated that their students had had very limited exposure to the outside world even before the COVID-19 pandemic: "[we] are a very small community, so a lot of kids don't know what's out there. They haven't been out in the real world. A lot of them haven't even traveled beyond our edge of our city." They indicated that the need for real-world connections to material presented in classrooms has become more important due to the pandemic because students have fewer opportunities to interact with the world outside the classroom and their home.

One concern/challenge: lack of synchronous, immediate support for remote students

All teachers expressed concern regarding what to do if a student would face technical trouble or struggle with the content in the educational technology used in a study in which they might participate (e.g., students might have trouble when they log into the system). Supporting students remotely during such an event would be challenging, compared to doing so in the in-person regular classroom, especially struggling students who "do not reach out to [the teacher] or to their friends and they wind up being stuck or they just give up because they're frustrated."

Discussion: recommendations for researchers

The interviews revealed findings regarding teachers' motivations for participating in research. First, study participation itself can and should be conceptualized as a learning opportunity for practitioners. Second, by participating in classroom research with educational technology, whether during a pandemic or not, teachers and students can not only learn about the learning materials used in the research but could also learn about aspects of educational research and a researcher's job. The interviews also uncovered concerns and challenges they perceive regarding participating in research, many of which are related to and may be unique to the remote teaching setting. We believe that conducting classroom studies virtually will remain important as schools may consider a virtual learning environment as one of the several possible teaching modes for the next several years. Based on the findings and recommendations from teachers, we provide three practical strategies that researchers can consider when conducting remote classroom studies during and after the COVID-19 pandemic:

First, we suggest that *researchers collect data about individual students' learning environment.* Under the remote learning setting, it is critical to understand and document that students may have different learning environments and that the amount and quality of support they get from parents and peers may be highly variable. Such differences could impact their participation, engagement, and learning during a classroom study.

Second, we suggest that *researchers make study participation simple and allow for flexibility*. Teachers are concerned about not being able to provide immediate support to students during the study, especially during remote instruction. This support pertains not only to content support but also to technical aspects such as logging in to the technology and streamlining the task procedure. Also, researchers should discuss with teachers what activities are most meaningful for their students to ensure that the study aligns with their classroom practice.

Lastly, it is important that *researchers make themselves present in classrooms and communicate with students appropriately.* Teachers reported that researchers' presence would motivate students. We recommend that researchers make themselves available virtually or in other ways, and offer an opportunity for students to interact with researchers whenever possible (e.g., by creating dedicated time for students to ask questions during a study session).

Learner Behavior and Career Benefits in Business Massive Open Online Courses

Anne Trumbore, University of Virginia, amtrumbore@gmail.com

Abstract: Adult learners claim career benefits from earning MOOC certificates, yet it is unclear if learning behaviors are correlated to these career benefits. This study examines the relationship between the learning behaviors and career benefits of learners who completed one or more of fifty business MOOCs. In a sample of 4063 learners, learning behaviors associated with persistence (videos watched and assessment attempts) were shown to be more strongly associated with perceived career benefits than either social behaviors (forum posts, comments, and views) or grades.

Purpose of study

Massive Open Online Courses (MOOCs), especially those in business or technical fields, can provide reputable and accessible educational content at an affordable price. Initially seen as a technological disruption of higher education (Yuan & Powell, 2013), they are now marketed as the solution to the ever-widening skills gap (Buhl et al., 2018). Recent scholarship shows that learners are reporting career gains from taking MOOCs (Hollands & Kazi, 2019a) and that learners who complete MOOCs to learn new skills are using the certificates earned in these courses to get hired or promoted (Hollands & Kazi, 2019b). Work has been done linking some forms of within-course behavior to career advancement, but only in one course (Wang et al., 2017). A study of behaviors associated with student completion in MOOCs was conducted across many courses (Andres et al., 2016), but this study did not examine career advancement after completion. The goal of this study is to determine if the learning behaviors which are correlated to completion across MOOCs are also linked to career benefits.

Methods

Wharton Online MOOCs are hosted on the Coursera platform which records learning behaviors such as video views, assessment attempts, forum posts, forum comments, forum views, and grades. A survey designed to measure career benefits was sent to a total of 101,986 learners who had completed at least one Wharton Online course through the Coursera platform from September 2015 through October 2019. The survey incorporated elements of a survey on motivation and career advancement developed by Hollands and Kazi, used with permission. Respondents were asked to rate whether or not they experienced career benefits on a 4-point Likert-style response from "Definitely yes" to Definitely no." "Completion" in Wharton Online courses is defined as earning a grade average of 70% or higher, which resulted in learners earning a certificate.

6321 learners began the survey, a 6.1% response rate, and 6189 learners (97.9%) consented to the study. 4341 learners answered Question 10 about whether or not they had experienced career benefits after taking the course(s). These learners' survey responses were matched to their course records, which included course grades, videos watched, assessment attempts, forum posts, forum comments, and the forum lurking ratio (i.e. forum views over forum posts). 278 learners were excluded from analysis because their survey email could not be matched to a learner i.d. Learning behaviors (videos watched, posts within forums, forum comments, forum views, grades on assessments, course grades earned) of 4063 survey respondents were tested for association with post-course career advancement using the non-parametric, Mann-Whitney U test to compare groups. The Benjamini & Hochberg (1995) method was used to control for false discovery rates: to verify that findings are not obtained solely due to running too many statistical tests.

Findings and discussion

Overall, the majority of learners reported that they experienced career benefits from Wharton Online MOOCs. 4319 learners answered the question about career benefits, and 3158 (73.1%) reported career benefits, while 1161 (26.9%) reported no benefits. Seven learning behaviors were examined: course performance (grades), videos watched in browser, assessment attempts, forum posts, forum comments, forum views, and the forum lurking ratio (forum views over forum posts). Each of these behaviors has been correlated with MOOC completion across multiple studies (Andres et al., 2016). However, only two of these seven behaviors—assessment attempts and videos watched in browser—correlated with career benefits (Table 1). Although forum activity has been correlated with post-course career development in earlier MOOCs (Wang et al., 2017), forum activity seems to have declined in more recent MOOCs (Poquet et al., 2018). One might reasonably assume that those learners who had higher grades would be more likely to report career benefits, yet that was not found. Correlation between assessment attempts and videos watched in browser could be due to grit (Wang & Baker, 2018) and/or self-regulated learning strategies (Kizilcec, Pérez-Sanagustin, et al., 2017), both of which have shown to be correlated to course completion. Another explanation for the correlation between assessment attempts and videos watched in a browser is the difficulty of the MOOC for learners. Learners who find the content new and/or more challenging may gain more knowledge and/or skills than those learners who engage less frequently with content.

Table 1: Results of Mann Whitney U Test and Adjusted α for Learning Behaviors by Career Benefits

Behavior	Mann Whitney U	Adjusted α
Course Grades	U(Nbenefits=2604, Nno benefits=935)=1171541, z=-1.711, p=.087	.021
Assessment Attempts	**U(Nbenefits=2965, Nno benefits=1098)=1523776, z=-3.141, p=.002**	**.007**
Video Starts Browser	**U(Nbenefits=2965, Nno benefits=1098)=1538169, z=-2.796, p=.005**	**.014**
Forum Posts	U(Nbenefits=2965, Nno benefits=1098)=16217951, z=-.653, p=.513	.043
Forum Comments	U(Nbenefits=2965, Nno benefits=1098)=1626243, z=-.081, p=.935	.05
Forum Views	U(Nbenefits=2965, Nno benefits=1098)=1626243, z=-.081, p=.935	.029
Lurking Ratio	U(Nbenefits=2965, Nno benefits=1098)=1610393, z=-1.050, p=.294	.036

Conclusion

The findings of this study show that the majority of learners who complete Wharton Online MOOCs report career benefits, particularly those who engage more with course content by attempting assessments more frequently and watching more videos in a browser. Because MOOCs can be taken by learners "in the flow of work" (Arets, 2016), they may be a source of more immediate career benefits than residential degree programs. This research can provide guidance for faculty and instructional designers in developing interventions that encourage those learning behaviors that are correlated with career benefits and may be useful for learners seeking career benefits.

Associations between Parenting Stress and Children's Academic Engagement when Schools were closed during the COVID-19 Pandemic: Risk and Protective Factors

Antje von Suchodoletz, New York University Abu Dhabi, avs5@nyu.edu
Susanna Fullmer, Brigham Young University, susannatfullmer@gmail.com
Ross Larsen, Brigham Young University, ross.larsen@byu.edu

Introduction

When many governments announced nationwide school closures in March 2020 to contain the spread of the COVID-19 pandemic, the context for and nature of educational interactions changed radically (Parczewska, 2020). Simultaneously, millions of parents were turned into "accidental homeschoolers" (Burke, 2020). Informed by the Family Stress Model (Masarik & Conger, 2017), the present study investigated associations in homeschooling during the COVID-19 pandemic between parenting stress and children's engagement, i.e., children's active involvement in a learning activity. The Family Stress Model argues that economic hardship and pressures increase the risk of parental distress, which in turn increases the probability of interparental relationship problems and disrupted parenting. When parenting is affected by these dynamics, child adjustment problems tend to emerge and influence children's development. Various factors may exacerbate (risk factors) or mitigate (protective factors) the family stress process (for a review see Masarik & Conger, 2017).

The present study investigated associations between parenting stress and children's academic engagement when school were closed during the first spike of COVID-19 infections in spring/early summer 2020. More specifically, main and interactive effects of various risk and protective factors of parenting stress in relation to children's engagement in at-home education were examined, where children's engagement was viewed in four dimensions: behavioral, agentic, cognitive, and emotional. We hypothesized that parenting stress is negatively associated with children's engagement. We also expected risk factors to be related with higher levels of self-reported parenting stress and lower levels of children's engagement, and supportive factors with lower levels of self-reported parenting stress and higher levels of children's engagement.

Methods

Participants were recruited in the United States from advertisements on Facebook and by word of mouth. The total sample included 78 US-American families. For these families, data was available from 75 mothers and 54 fathers who completed the survey. Parents were asked to refer to their firstborn child who was homeschooled at the time of data collection as the subject of this study. Complete information from mother-father-child triads was available for 40 families. Partially complete information was available for mother and child in 46 families, and for father and child in 40 families.

Parents were asked to report their perceived parenting stress. Assessed risk factors included spousal relationship quality, health problems, number of children homeschooled and time in week in emergency homeschooling. Protective factors included perceived support from school and satisfaction with school support, and parents' online social network. The child was asked about his/her liking of homeschooling and engagement with homeschooling. The same questions about the child's engagement with homeschooling were also included in the parent survey.

All engagement variables, as well as, parenting stress, interparental relationship problems, and parent health problems were modeled as latent variables. Engagement variables were assessed using a modified scale from Reeves (2013). To measure parenting stress, we used the parenting stress items from the Fragile Families and Child Wellbeing Study (Cooper, McLanahan, Meadows, & Brookes-Gunn, 2009). Both interparental relationship problems and parent health used subscales from the Parenting Stress Index (PSI; Abidin,1995). All other variables included in the study were measured as manifest variables.

To account for the different respondents, the models were run with various combinations of respondent-reported variables. Models varied by which respondent reported parenting stress, risk/protective factors, and child's engagement. The combinations included mother-reported parenting stress and risk/protective factors on mother-reported child engagement (model M-M), mother-reported parenting stress and risk/protective factors on child-reported child engagement (model M-C), father-reported parenting stress and risk/protective factors on father-reported child engagement (model F-F), and father-reported parenting stress and risk/protective factors on child-reported child engagement (F-C). Due to the number of models run, a Bonferroni alpha correction was applied (yielding a minimum significance level of $p<0.0125$).

Additionally, we created interactions between parenting stress and the protective and risk factors, as well as an interaction between parenting stress and child liking of homeschool. Models were run first with only main effects, then again with the interactions. Models were trimmed using the Bonferroni alpha correction to only include significant interactions.

Results and discussion

Contrary to our hypothesis, no significant direct associations between parenting stress and children's engagement were found. This is true apart from model F-F, in which case parenting stress had a negative relationship with behavioral and emotional engagement.

However, when including interactive effects with parenting stress, the interactions were found to have significant associations with children's engagement. This indicates that parenting stress does have a significant association with children's engagement when considered in combination with other factors. For model M-M and model F-C, the interaction between parenting stress and children's liking of school was found to be significantly associated with children's engagement. More specifically, in model M-M, the interaction was significantly associated with all four types of children's engagement, and, in model F-C, the interaction was significantly associated with behavioral and agentic engagement. Plots of the interactions confirmed the same conclusion that the optimal combination for a high engagement score resulted from high child-liking of homeschooling with low parenting stress. For model M-C, the interaction term significantly associated with children's engagement, namely behavioral, cognitive, and emotional engagement, was parenting stress combined with length of homeschooling. In the context of high levels of parenting stress, possible negative effects on children's engagement were buffered when the homeschooling lasted for fewer weeks. Model F-F had no significant associations between any interaction terms and children's engagement.

For models M-M and M-C, our hypothesis of risk factors relating to higher parenting stress and lower children's engagement was not evident in terms of the main effects. However, the interaction of the risk factor length of homeschooling with parenting stress did have a significant association with children's engagement in model M-C as mentioned above. For models F-F and F-C, a relationship between risk factors and parenting stress emerged, while no relationship between risk factors and children's engagement was evident. In model F-C, parent's health had a negative relationship with parenting stress and in model F-F, parent's health as well as number of children homeschooled had a negative relationship with parenting stress.

For supportive factors, models M-M and M-C indicated relationships between supportive factors and parenting stress but not children's engagement while models F-F and F-C indicated relationships between supportive factors and children's engagement but not parenting stress. In models M-M and M-C, school support for at-home education had a positive relationship with parenting stress and the size of the mom's online social network had a negative relationship with parenting stress. In model F-F, both the father's satisfaction with school support and intensity of content management on social media related to at-home education had a positive relationship with emotional engagement. In model F-C, the size of the father's online social network had a positive relationship with agentic engagement.

In summary, our study identified potential risk and protective factors of children's engagement that could inform prevention and intervention at multiple levels to promote academic functioning, in particular among children at risk of falling behind.

An Interplay of Problem-Solving Modes and Authority: Framework for Equitable Collaboration in Undergraduate Physics Labs

Sophia Jeon, Cornell University, mj398@cornell.edu
N. G. Holmes, Cornell University, ngholmes@cornell.edu
Eleanor C. Sayre, Kansas State University, esayre@gmail.com
Scott Franklin, Rochester Institute of Technology, svfsps@rit.edu

Abstract: We use the Adaptor-Innovator Theory and the Influence framework to interpret undergraduate physics laboratory students' approaches to – and bids for – intellectual and directive authority. Students display behaviors that utilize structure and work within a defined system (adaptor) and, separately, behaviors that work outside the system (innovator), the latter often by engaging directly with equipment. Adaptors exhibit high authority by asserting experimental understanding, whereas innovators are attributed with high authority through their frequent, direct handling of the equipment. We interpret equitable collaborations as those in which students 1) have full access to the experimental or conversational floor adaptively or innovatively while being 2) acknowledged in their authority by their group.

Keywords: problem-solving, equity, collaboration, Adaptation-Innovation Theory, authority

Theoretical framework

Although group work is an important form of learning for undergraduate STEM students, improving problem-solving skills and content understanding, identity-based performance gaps persist (Heller & Hollabaugh, 1992; Madsen et al., 2013). We examine undergraduate physics lab students' group dynamics, integrating the Adaptor-Innovator Theory (AI Theory) and the Influence Framework to interpret problem-solving behavior and frame a definition for equitable collaborations (Kirton, 2011; Langer-Osuna, 2016).

In AI theory, *adaptors* approach problems methodically, using given structures (Simpson, 2019). We observe three adaptor mode behavioral markers: i) seeking instruction, ii) defining the system, and iii) adhering to a manual. Conversely, *innovators* "problem solve by working outside of the system, sometimes creating radical changes" (Simpson, 2019). Innovator mode behavioral markers include: i) frequently handling equipment, ii) generating new ideas, and iii) exploring with curiosity. Individuals can exhibit both modes, and behaviors exist on a continuum, with the degree depending on context (Kirton, 2011; Kirton, 1980).

Students negotiate problem-solving modes through authority, and seek acknowledgment in their preferential approaches. The Influence Framework defines two types of authority: *intellectual authority* is perceived "as credible sources of information pertinent to the particular task at hand", while *directive authority* makes commands or suggestions to steer a course of action (Langer-Osuna, 2016). We find that acknowledgement in authority differs with the AI mode accessed: innovators are *attributed* with authority as they handle the equipment, whereas adaptors *claim* authority by asserting experimental understanding.

Table 1: Behavioral markers of adaptor and innovator modes and authority.

Adaptor-Innovator Theory		Influence Framework	
Modes	**Behavioral Markers**	**Authority**	**Behavioral Markers**
Adaptor	•Asks for and seeks instruction •Defines the system at hand •Appeals to lab manual	**Intellectual Authority**	•Perceived as an important source of information, asked questions by peers •Makes claims about experiment
Innovator	•Frequently handles equipment, not afraid to make changes. •Generates ideas outside of manual •Expresses curiosity in equipment	**Directive Authority**	•Makes directives to peers •Prompts actions on the equipment •Perceived as one that confirms bids

Methods

In this study, one researcher observed videos of students collaborating on advanced physics lab experiments at a public research university in the midwestern United States. The course is populated by second- and third-year physics majors and minors. After transcribing student discourse, the researcher coded for moments of high or low levels of intellectual and directive authority and when students approached problems adaptively or innovatively. Codes were confirmed with another researcher, who separately analyzed the videos, and organized into the codebook shown in Table 1, which describes the various behavioral markers.

Manifestation of problem-solving modes and authority and frame of equity

Students demonstrated behavioral markers of adaptors and innovators, moving fluidly between the two. For example, we observed a student to initially access the innovator mode, saying, “I kind of want to just start trying things” (unafraid to make changes on equipment), and later access the adaptor mode, saying, “We have to be really careful because of the cord in the back…that's what the manual was talking about” (appeals to lab manual). When a group attempts to access different problem-solving modes simultaneously, they express a preference through bids for authority. Their level of authority depends on how their peers respond to their ideas, and does not necessarily correlate with confidence or AI modes. For example, one innovator says, “I’m gonna start flipping these knobs…I don’t know.” Though he is unsure of his actions, the group affords him intellectual authority, perceiving him as a source of important information. In another group, an adaptor claims directive authority by proposing tasks and responsibilities: “Someone should be the ring measurer, someone should keep an eye on voltage.” She opens up the conversational floor—indicating influence—by asking “Who wants to be the ring measurer?” Her partners acknowledge her directive authority by taking on various roles and asking clarifying questions. Students with high intellectual authority are acknowledged by their peers; students with low intellectual authority, in contrast, are often unheard by the group even after expressing their thoughts.

We observe low authority when students are not given access to the conversational nor experimental floor, despite explicit bids. For instance, when one student suggests that the group ask the professor for confirmation, a partner rejects this bid for directive authority and instead asks the third member: “Should we turn it to, like, 500 and plug it in just to see?” The second student nevertheless persists, interjecting “Yeah, I would just say. Test it first and then we can actually start taking data.” Bids for authority may be rejected when students have differing problem-solving modes. In this example, we observed an adaptor reading from the lab manual in a bid for directive authority, which is rejected by the innovators directly handling the equipment.

We interpret equity as the ability to access the experimental or conversational floor and be acknowledged in one’s authority to approach problems adaptively or innovatively. For example, a student adjacent to a monitor may be unable to see the lab equipment, and thus have limited access to the experimental floor. Participation would therefore require explicit interjection into ongoing discussions, which are often ignored. When one student asks, “Do you know how to use an oscilloscope?”, the other responds with “Kind of,” ignoring the marginalized third member’s response of “Yes.” Here we see the inequity of access to the conversational and, thus, experimental floors to decrease group productivity, as the member with knowledge has been denied intellectual authority. When student authority is acknowledged, students can participate fully and thus equitably in their problem-solving collaboration. Inequities, however, are produced when students are marginalized by peers that dominate in authority or do not recognize bids because of a different problem-solving mode. The balance fluctuates throughout a lab, with moments of inequity interspersed with moments of equity.

Abstract: This paper reports a design science research methodology (DSRM) study that develops, demonstrates, and evaluates a deep learning model utilizing multimodal data to automatically detect types of interactions for regulation in collaborative learning (RegCL) by using features extracted from electrodermal activity (EDA), video, and audio data involving secondary school students (N = 94). RegCL offers novel and essential opportunities to advance research on Socially Shared Regulation of Learning in groups (SSRL).

Keywords: Self-regulated learning, socially shared regulation, design science research, collaborative learning, machine learning.

Multimodal deep learning model to detect interactions for regulation in collaborative learning (RegCL)

In recent years, the social aspects of regulation in general, and socially shared regulation in collaborative learning in specific, have gained the increasing attention from educational researchers (Malmberg et al., 2017). However, it is still challenging to assess and support the regulatory processes in interactions because of the "unobservability" of the processes at all levels, including cognition, metacognition, emotions, and motivation. In this study, we attempt to complement the design science research methodology (DSRM) approach with learning theories and machine learning algorithms to create a multimodal deep learning model for detecting types of interactions for regulation in collaborative learning. The model is conceptualized from self-regulated learning and socially shared regulation theory and designed based on multimodal data collected from a collaborative learning context.

We capture students' physiological activities through the measurement of Electrodermal Activity (EDA), and the visual and acoustic data reflecting engagement in learning activities in the classrooms' natural setting involving secondary school students (N = 94) working collaboratively in groups of three or four during five physics lessons. The types of interactions for regulation were classified using four separate labels: 1) metacognitive interaction, 2) socio-emotional-interaction, 3) task execution and 4) other interactions. Through the design and development of the deep learning model, we provide preliminary answers to the following research question: Is there evidence that SSRL processes can be automatically detected within the challenging learning situations and their related interactions? In other words, do we have evidence in favor of the feasibility of using multimodal and advanced technologies in support of SSRL?

Based on a review of previous multimodal deep learning frameworks, we designed a multimodal deep

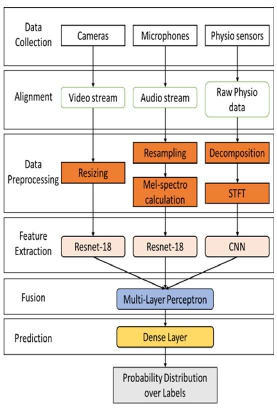

Figure 1. Multimodal Deep Learning Model to Detect Regulation Interactions in Collaborative Learning (RegCL)

learning model to detect interactions for regulation in collaborative learning (RegCL) as demonstrated in Figure 2. RegCL transforms the multimodal data from three modalities (i.e., video, audio, and electrodermal activity (EDA)) through a series of stages including Data Collection, Alignment, Preprocessing, Feature Extraction, and Fusion then passed through what is called a dense layer for the final prediction.

We conducted deep learning experiments on a randomly selected subset of the collected multimodal data with 3232 data pieces splitting into a training set (2459 data pieces), validation set (392 data pieces), and test set (381 data pieces) with the ratio of 8:1:1. The testing results show that fusing the features of multimodalities (audio-video-EDA) has significantly higher performance than models using video ($t = 5.509$, $p < 0.001$) or EDA ($t = 4.036$, $p < 0.001$) alone. Our demonstration and evaluation of the RegCL model provides evidence supporting the research proposition by Järvelä et al. (2019) provisioning that using advanced technologies on multimodal data holds to potential to reveal the "invisible" process of regulation in learning.

Discussion and conclusion

This study introduced the potential of multimodal deep learning to recognize types of interaction closely related to regulation in collaborative learning. It is important to note that we did not yet study regulation as such, since additional data and a qualitative approach is needed to understand that. The use of data collected from different modalities such as textual dialog transcripts, interaction events, video, and psychophysiological data offers a substantial promise for addressing the problem of understanding regulation in collaboration (Järvelä et al., 2020). The literature has also recognized several issues related to unfolding the social aspects of learning regulation to advance the operationalization of the concept of socially shared regulation in collaborative learning (Järvelä et al., 2019; Malmberg et al., 2017). This study attempts to bring together the powerful capabilities of affective computing and machine learning to address the methodological challenges for leveraging theoretical and practical foundations of learning regulation. The adoption of advanced technologies such as deep learning and multimodal data in this preliminary investigation have provided a proof-of-concept offering hope for eventually addressing the identified challenges.

"A Person with a Big Lengua": Productive Callouts in Whole Class Discussions

Maggie Dahn, University of California-Irvine, dahnm@uci.edu

Abstract: Voice can be conceived of as a project developing across time and situation as teachers and students co-construct how voice is locally defined through the social organization of classroom interactions. Using sociocultural theory as a grounding framework, this study illustrates how sixth grade students "had a voice" in whole class conversations and discusses implications for supporting collaborative, democratic, and heterogenous discussion spaces.

Introduction

Voice has been conceived of as a project developing across time and situation that can be supported in schools and classrooms (Lensmire, 1998). Here I build from Lensmire's conception of voice as a project to frame voice as an interactional accomplishment related to how sixth grade students and a teacher (myself) participated in whole class discussions as part of a visual arts unit focused on making art about student-defined social issues (e.g., immigration, racism). Within the social organization of the visual arts classroom, I am interested in how students "had a voice" in whole class conversations. This poster focuses on how voice developed on the interpersonal plane (Rogoff, 1995) with consideration of the research question: *How did the teacher and students co-construct voice in the local classroom context during whole class discussions about social issues and art making?*

Voice as an interactional accomplishment in a whole class participation frame

In classrooms, students orient toward one another within different participation frameworks (e.g., Goodwin, 2007) that influence what they notice and attend to. Classrooms also operate within historical and cultural frames that carry traditional norms of participation (i.e., teachers stand at the front of the class and teach, students sit, listen, and learn), yet participant roles and norms are in constant negotiation as students and teachers align with, resist, and disrupt these traditional norms in sociocultural interactions. Rogoff (1995) argues that sociocultural development operates on "three planes": the community/institutional, the interpersonal, and the personal. This study focuses on *the interpersonal plane* constituted by social interactions in whole class discussions.

Methods

The study site was a sixth grade visual arts class (n=32) at a public charter middle school named Esperanza Prep, situated in a working class Latinx community in Los Angeles County. 97% of students identified as Latinx, and 92% qualified for free or reduced-price lunch. I was previously the kindergarten through third grade visual arts teacher at the school and so many participants were my former students. Sociocultural theories of learning informed my approach to teaching and instructional design of a 20-lesson visual arts unit in which students made art about self-defined social issues. Relevant data sources included lesson activity logs, video transcripts, and field notes. For this study, in analysis of activity logs of all whole class discussions, I used an iterative, open coding process to find common patterns of interaction that were consequential for how participants "had a voice."

Findings

Table 1: Patterns of interaction consequential for co-construction of student voice in whole class discussions

Pattern of voice	What did the pattern *do for students*?	What did the pattern *mean for voice*?
(1) Bursts of prompted and unprompted conversation	Students could test, elaborate, and refine ideas in a smaller group before sharing more publicly	Voice is collaborative and builds from multiple contributions before being public
(2) Taking up of on-topic callouts	Students had agency to participate in ways that made sense to them and construct new norms	Voice is democratic; voice is co-constructed on the public floor
(3) Encouraging extension of ideas and offering different interpretations	Students elaborated on existing ideas and offered different perspectives based on prior experiences	Voice is heterogeneous; voice is a collection of diverse ideas shared in the public space

Table 1 shows the three salient patterns of interaction, including what they did for students and defining voice. Below, I illustrate the second pattern through an example from the third lesson during which students talked about social issues to motivate their art making. After sharing with partners, I asked students to make a class list of social issues. During this whole class conversation I began by calling on students in a traditional classroom turn-taking structure. Student contributions included "cyberbullying," "DACA," "deporting/la migra," and "police."

Students jumped in to add ideas, resulting in a repeated pattern of several students calling out at once. One student, Ariel, then offered the example of “Donald Trump” as a social issue, explaining:

> The NFL took the knee, they were doing the flag something and what’s going on with Mexico, and they had an invitation to the White House, but Donald Trump doesn't want them to go to the White House, and now he gave the invitation to some sport that only white people do.

Many students then started talking at once. In moments like these when the class took over, I noticed that students were participating in ways that made sense to them; their engagement was evident as some were physically getting out of their seats to contribute. In this case, I was aware of students’ desire to be heard as well as my positionality as a white woman within Ariel’s comment. Rather than elaborating on Ariel’s contribution, my intentional move of stepping back to listen left space for other students to speak. Once the conversation quieted, I offered the floor back to Ariel. She elaborated and others continued to make on-topic callouts, including Ken’s declaration that Trump is just “a person with a big lengua” in Excerpt 01, turn 02. The continued exchange reified on-topic call outs as a legitimate form of participation, strengthening its position as a new class discussion norm.

<u>Excerpt 1.</u>

Turn	**Speaker**	**Talk and *Action***
01	Ariel	It's kind of like that, but like when he speaks, he doesn't know how to stop his tongue 'cause he just doesn't think about it. *Teacher nods and says okay; many students nod or utter agreement*
02	Ken	He's a person with a big lengua *Ken calls out; many students laugh*
03	Mrs. Dahn	I'm gonna put in like a question mark, Donald Trump, to think about-
04	Benjamin	*Benjamin calls out* -racism
05	Oscar	*Oscar calls out* He doesn't want Curry to go to the White House
06	Mrs. Dahn	He, he makes us think about a lot- *Some students continue talking about the topic*
07	Ariel	*Ariel calls out* -and he wants to create America better again. How is that happening? *Many students talk at once*

Because the topics discussed were meaningful and emotional for students, they felt comfortable calling out, adding on, and supporting one another’s contributions in the whole class discussion space. Their overlapping talk and collective storytelling became a co-constructed part of the classroom culture and defining voice. By stepping back and allowing students to take over conversations, as the teacher, I offered students opportunities to take up space. This pattern of interaction allowed for public testing of private ideas. Voice was therefore democratic and about bringing individual and privately constructed ideas to the public floor to be further developed.

Discussion

The three patterns—bursts of partner talk, taking up of productive, on-topic callouts, and extending ideas about art and offering conflicting interpretations—–illustrate broadly how students and I co-constructed voice in whole class discussions. The second pattern illustrated here supported the co-construction of having a voice as something that was democratic and vetted on the interpersonal plane (Rogoff, 1995). This study has implications for how researchers conceive of student voice in classrooms as it takes students’ and teachers’ interactions and norm disruptions as part of a process (and project) of co-constructing voice. Additionally, this study has implications for design of collaborative, democratic, and heterogenous classroom discussion spaces.

Engagement patterns in an asynchronous virtual classroom: Different use of active observation and ICAP framework

Ji Young Lim, Kyu Yon Lim,
jylim.edu@ewhain.net, klim@ewha.ac.kr,
Ewha Womans University

Abstract: This study investigates the impact of active observation mode in an asynchronous virtual classroom. Active observation, operationally defined as observing the learning activities of oneself or other learners, was compared to the modes suggested from ICAP framework. It was found that high-performing learners engaged more frequently in monitoring oneself and other's activities (active observation), while low-performing learners engaged more frequently in simply watching video lectures (Passive mode of ICAP framework).

Objectives and research question

This case study aims to propose the use of *active observation* for the design of an asynchronous virtual classroom. Based on the ICAP framework, the guiding ideas of this study were: (a) if the behavioral engagement pattern in active observation mode is distinguished from the other modes of ICAP framework, and (2) if the impact of active observation is different from the impact of other modes, then the active observation can be included as the additional mode of ICAP framework in online learning. Research question was generated: In an asynchronous virtual classroom, does the access patterns are different between high- and low-performing learners to each mode of the ICAP framework and active observation mode?

Backgrounds of the study

One of the biggest challenges of an asynchronous virtual classroom is to promote learning engagement. In this sense, the ICAP framework proposes that the distinguished nature of overt learning activities brings different levels of cognitive engagement (Chi & Wylie, 2014). ICAP modes of engagement include: **P**assive mode: receiving information (e.g., watching videos); **A**ctive mode: actively manipulating learning materials (e.g., pausing video); **C**onstructive mode: generating outputs (e.g., posing questions); and **I**nteractive mode: an action followed by other's reactions (e.g., discussion). **I**nteractive activities lead to deeper cognitive engagement than **P**assive activities (Chi & Wylie, 2014).

However, more studies are needed to use ICAP framework for designing virtual classroom. Existing sudies suggest that learners may find it challenging to access **I**nteractive and **C**onstructive modes in the online learning environment (e.g., Haney et al., 2016). In contrast, Wekerle and colleagues (2020) suggested that learners feel more encouraged when they are engaged in **C**onstructive activities.

An asynchronous virtual learning environment provides a learning experience that is hard to attain in a face-to-face classroom. *Active* ***o****bservation* in this study is operationally defined as *observing how learners (including oneself and others) engage in online learning*. According to ICAP framework, observation is regarded as *passive* mode, but it does not cover observing learners. Also, manipulating learning materials (**A**ctive) is more overt behavior than active observation, which does not include bringing any kinds of visible changes. **A**ctive **o**bservation is also not involved in **C**onstructive or **I**nteractive mode. When learners generate ideas and post them on the discussion board (**C**onstructive), other learners can read them and reflect accordingly. It can happen even when they do not engage in discussion (**I**nteractive).

Active observation is a distinguished affordance provided in virtual learning environments. Herrington and colleagues (2003) stated that providing opportunities for learners to reflect on their learning is one of the defining characteristics of authentic online learning environments. When learners engage in activities online, those remain as learning-footprints for other learners and as records for themselves. These facilitate internal feedback (learning by comparing and reflecting; Nicol, 2020) and observational learning (Bandura, 2008).

Methods

In this case study, the *participants* included 36 female undergraduate students from the college of education who were enrolled in the instructional design class. Course materials and online activities were uploaded weekly using the Moodle-based Learning Management System (LMS). After four weeks, students participated in online quizzes.

Learning Materials were developed as follow: **P**assive mode: accessing video lectures (week 1-4); **A**ctive observation mode: accessing various types of boards where learners can postings or comments others uploaded (week 1-4); **C**onstructive mode: the number of uploading posts (week 1-4); **I**nteractive mode: uploading comments to other's postings or comments (week 1, 3-4). In this class, **A**ctive mode in the original ICAP framework was not included due to the technological constraints of the LMS.

Measurement and analysis used for this study are as follows. *Log data* was collected from the Moodle-based LMS. The data contained the frequency of access by the users. Since the number of content varied each week, the data were standardized to t-value. For example, to calculate an individual's t-value for the Passive mode in the 1st week, the sum of the frequencies of access to two video lectures was calculated and standardized to t-value based on the average of the total frequency of access among all participants. The *outcome* was measured using an online quiz.Ten multiple-choice type questionnaire items were presented. The analytical processes are as follows: First, based on the final quiz score, the top 40.0% (13 participants, high-performing learners, HL) and the bottom 40.0% (14 participants, low-performing learners, LL) were selected from the data for comparison. Second, the average of t-values for each mode was calculated.

Results

The access patterns of each mode over time was different from each other (see Figure1). In terms of **P**assive mode, the LL participated more frequently than HL for all weeks. For the **A**ctive **o**bservation mode, The HL participated more frequently than the LL except in week 2. Regarding **C**onstructive mode, inconsistent pattern was observed across weeks. For the **I**nteractive mode, HL participated more frequently than LL except for week 1.

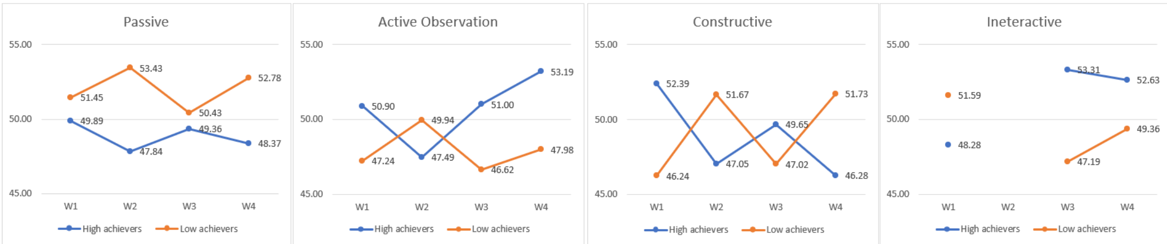

Figure 1. Access patterns over time for each mode

Implications for virtual classroom design

Implications are suggested based on the results. First, in an asynchronous virtual classroom, designing **I**nteractive modes may be more desirable than Passive modes: The result showed the differential access patterns under **P**assive and **I**nteractive modes between the HL and LL, as reported in the previous studies (Chi et al., 2018; Lim et al., 2019). Second, the differential access patterns for **a**ctive **o**bservation under the other ICAP modes support the study hypothesis. HL group engaged more in active observation overall except during the 2nd week, in contrast to the LL group, which engaged more in **P**assive mode in all weeks. This shows that although both **P**assive and **a**ctive **o**bservation modes entail observation, the target of observation in online learning can elicit different impacts on learning outcomes. It is also worth note that although both HL and LL learners engage in generating ideas, high-achieving learners tend to monitor and reflect based on observing how others do for learning.

Considering K-12 Learners' Use of Bayesian Methods

Joshua M. Rosenberg, University of Tennessee, Knoxville, jmrosenberg@utk.edu
Marcus Kubsch, IPN – Leibniz Institute for Science and Mathematics Education, kubsch@leibniz-ipn.de

Abstract: Bayesian statistical methods have become increasingly widely-used by statisticians, scientists, and engineers, yet their use has remained within the purview of professionals—and not learners, especially those at the K-12 level. At the same time, decades of developmental research indicates that children learn about the world in ways that align with Bayesian models of cognition. In this paper, we review prior research on Bayesian methods and learning, and offer specific, targeted areas where we think that Bayesian methods could have make an impact, and then discuss future directions for Bayesian methods as a conceptual and statistical tool for learners.

Introduction

From a Bayesian perspective, probability and degrees of certainty are central. From this perspective, probability is used to describe the state of our knowledge about the world. Bayes Theorem, then, provides a rigorous and coherent mathematical framework to update our knowledge about the world, that is, learn, based on data and what we already know. Results from a Bayesian analysis quantify our (un)certainty about parameters.

Bayesian methods allow us to make statements based on our prior knowledge as well as the data; statements such as "Given much earlier studies and the data we collected in our study, the credible range of the length of *Ambystoma maculatom* is from 5.85-6.42 cm., with 6.17 as the most likely length." In contrast, a frequentist perspective conceptualizes probability in terms of infinite repeat sampling: Frequentist methods aim at estimating the value of the one true parameter based on models about the sampling process and sampling distribution. In consequence, results from a frequentist analysis would phrase the result about salamander lengths in the following terms: "Over many samples of *Ambystoma maculatom*, 95% of length measurements will fall in the confidence interval of 5.85-6.43 cm. (β = 6.20, SE = .44, p < .05)" In sum, Bayesian methods readily allow analysts (at any age) to incorporate existing subject-matter knowledge into their analysis and to interpret results in a more intuitive way that aligns better with how people think about the world.

Bayesian methods have not only been used by statisticians, although that is their provenance: Recent research has translated Bayesian ideas beyond their statistical provenance, particularly into the domain of developmental science. This work, broadly, highlights how children intuitively view the world in a Bayesian way (Gopnik, 2012). This paper is predicated on the possibility that the utility of Bayesian ideas to questions about how children *develop* might also have a bearing on how children and youth *learn*, especially in the context of interest on the part of learning scientists in data science and statistics education (Wilkerson & Polman, 2020).

Our goal, then, is to introduce Bayesian methods as an underutilized tool for learners. To do so, we offer two examples of the potential for Bayesian ideas and methods in learning sciences-related areas of research.

The potential for Bayes in learning sciences-related areas of research

Bayesian methods have the potential to bring a new perspective to questions that learning sciences researchers presently ask. In the following, we outline two examples—one from science education and one on the topic of conceptual change—of how a Bayesian perspective may help to redress existing learning-related challenges.

Probability and chance events play an important role in the life sciences, particularly in evolutionary processes and learning about them (Tibell & Harms, 2017). Recently, Fiedler et al. (2019) found that statistical reasoning accounted for nearly a third of the variance in students' knowledge about evolution. Thus, supporting students' statistical reasoning could greatly improve their learning about evolution. Given that research on students' statistical reasoning in the context of evolution has been predominantly approached from a frequentist paradigm (e.g., Fiedler et al., 2019), the potential of a Bayesian perspective remains largely unexplored. Bayesian methods could be useful because a Bayesian view of probability may align better with the ideas about statistics that learners already possess (Gigerenzer & Hoffrage, 1995) or amassing evidence suggesting that human cognition generally follows Bayesian principles (Gopnik, 2012). Thus, we think Bayesian methods could have particular utility in learning about evolutionary processes, and, more generally, probabilistic processes in scientific phenomena.

Bayesian models of cognition may also help to solve a riddle that has vexed the conceptual change literature for some time – the refutation text effect (Broughton et al., 2010). In contrast to traditional expository texts, refutation texts a) state a misconception, b) explicitly show how the misconception does not fully address the issue at hand, then c) present the accepted scientific position as an alternative. Numerous studies have demonstrated that such texts are very effective in facilitating conceptual change across a range of topics and domains; however, the nature of these effects remains to be little understood and an active area of research (e.g., Mason et al., 2019). Bayesian models of cognition offer a straightforward explanation of many different findings concerning the effects of refutation texts: Students' misconceptions are ideas about concepts acquired through everyday observations which prove to be effective in the contexts in which they are acquired. As an example, consider how children often think that only living things have energy (Watts, 1983). From a Bayesian perspective, the evaluation of the question can be framed as follows: the misconception that only living things have energy reflects a very strong prior for the association between being alive and having energy. A refutation text could help the reader to reevaluate their prior knowledge, and, thus, to weight new information (e.g., information about airplanes in flight having energy) more relative to their prior ideas. Scholars have begun to successfully model students' conceptual development in a Bayesian framework (Bonawitz et al., 2019). This and the above example illustrate how Bayesian methods can be applied to already-active areas of research. In the future, Bayesian methods may also invite new research questions for learning scientists.

Future directions for research

Advances in technological tools and statistical software may make the conceptual accessibility of Bayesian methods more technically accessible; one encouraging example of such a technological tool is the JASP statistical software (JASP Team, 2020), which allows for Bayesian models to be estimated as easily as frequentist models (even for models as foundational as *t*-tests and linear models); JASP also has features that are in line with what is known about the development of statistical software that is useable by learners (McNamara, 2019). Technological tools coupled with design-based research may prove to be helpful for understanding whether, when, and how Bayesian methods and tools have a role in K-12 contexts.

Looking ahead, Bayesian methods have proven to be useful to professionals, and Bayesian ideas about how individuals develop (e.g., Gopnik, 2012) suggest that there are opportunities to connect the thinking that children already do with how they learn. Though it may appear far-fetched for tenth-grade students, for example, to apply advanced statistical methods, we are collaboratively working to integrate Bayesian methods into science classrooms—including one of this paper's author's classroom—by shifting the focus away from hypothesis testing and toward understanding variation in data and exploring how arguing from evidence can serve as a context for learners to bring their ideas about how the world works into their scientific explanations.

Investigating Children's Problem-Solving Patterns in Digital Game-Based Learning for Computational Thinking Development

Zhichun Liu, University of Massachusetts Dartmouth, liulukas91@gmail.com
Jewoong Moon, Florida State University, jewoon.moon@gmail.com

Abstract: Developing computational thinking (CT) in digital game-based learning through problem solving is challenging to younger children. In this study, we investigated 79 children's in-game sequential problem-solving patterns in a CT game – *Penguin Go*. We found three in-game problem-solving patterns (i.e., solution implementation, consecutive implementation, and solution evaluation) and confirmed that children's problem-solving patterns predicted CT development at near and far transfer on CT. Based on the study findings, we also discuss design implications.

Keywords: Digital game-based learning, computational thinking, problem solving, sequential data analytics

Introduction

The recent prevalence of modern computing technologies and artificial intelligence has drawn attention to computing education for the next generation. Hence, increasing interest arises regarding how to incorporate the notion of computational thinking (CT) into the elementary curriculum worldwide (McGill & Decker, 2020) Several DGBL studies aimed at promoting children's CT development through in-game problem-solving experiences (Zhao & Shute, 2019). Specifically, DGBL benefits students to understand underlying game logics and rules that drive CT development by in-game failures and success experiences.

However, research has indicated that young children are likely to experience cognitive challenges in gameplay. Such challenges may yield unsystematic behaviors during in-game problem solving and learning transfer failure due to their limited uses of cognitive and metacognitive resources (Liu et al., 2017). Understanding children's in-game problem-solving patterns is essential because it indicates students' gameplay patterns representing diverse needs and challenges at different learning stages.

In this study, we aim at investigating the relationship between children's in-game problem-solving patterns and CT development through identifying emerging behavioral patterns by sequential pattern mining. Our research questions are:

(1) What are children's in-game problem-solving patterns in the game *Penguin Go*?
(2) To what extent do the in-game problem-solving patterns predict children's CT development?

Method

Study procedure

Penguin Go (PG) is an educational game teaching block-based programming language designed to enhance young children's CT development (Zhao & Shute, 2019). Seventy-nine children between 9 to 11 years old from diverse ethnic backgrounds were randomly assigned to either the treatment or the control version of Penguin Go. The control group accessed only the basic game mechanism support, while the treatment group received additional cognitive supports in the form of information prompts and partial worked-examples during the gameplay. Participants played *Penguin Go* for 135 minutes.

Gameplay data and sequential pattern mining

We collected computer logs from *Penguin Go* to identify students' game interactions. The log data contains students' game ID, game action, level, code, and timestamp. We conducted sequential pattern mining (SPM) to indicate students' emerging in-game problem-solving patterns. We aggregated individual gameplay data and arranged them based on each students' game ID and gameplay sequences. We used the *cSPADE* algorithm (Zaki, 2000) to identify frequent behavior patterns among various in-game sequences in a given time period (*max_gap* = 2, *min_sup* = 0.5).

Results

RQ1. What are children's in-game problem-solving patterns in the game

A total of 28 gameplay sequences containing five unique behaviors were identified. Based on the characteristics of the identified gameplay sequences, we classified the identified sequences into three pattern categories (Table 1). Second, in comparison to SI and CI patterns, children showed less SE patterns, which denote that children tended to have trouble with systematic problem-solving. Third, the SPM result demonstrated children's rare interactions with embedded learning supports during gameplay.

Table 1: In-Game Problem-solving Pattern Categories

Category	Pattern description	Implications
Solution implementation (SI) (average support value = 0.81)	Start with a series of *Create Blocks* and end with *Run Blocks*.	Implements and executes a solution with a clear algorithm in mind. The frequent occurrence of the SI behavior indicates an inefficient problem-solving heuristic (e.g., trial-and-error).
Consecutive implementation (CI) (average support value = 0.80)	Only contains consecutive *Create Blocks* with no *Run Blocks*.	Does not have a clear plan of the algorithm, which indicates unsystematic exploration or sometimes random block creation.
Solution evaluation (SE) (average support value = 0.64)	Contains *Reset Blocks* in combination with *Run Blocks* or *Reset Blocks*.	Interrupts the solution execution. Involves prediction of where the penguin is moving and the evaluation of the solution. Often associate with debugging.

RQ2. Effect of in-game problem-solving patterns on CT development?

We then examined how the frequency of the in-game problem-solving patterns across all in-game sequences predicted children's CT performance at the near and far transfer level. In terms of the in-game problem-solving patterns, the results indicated that the CI pattern was a statistically significant predictor for the near transfer (t = 2.33, p = .02) but not for the far transfer performance (t = 1.21, p = .23). On the other hand, the frequency of SE behavior predicted the far transfer performance (t = 1.92, p = .06) with a marginal significance instead of the near transfer performance (t = -.94, p = .35). This result infers that debugging-related behaviors influenced learning transfer in the long run, although this pattern was not efficient for learning immediately. The frequency of SI pattern was not a significant predictor for neither near transfer performance nor the far transfer performance.

Discussion and conclusion

The results displayed that children experienced inefficient and unsystematic problem-solving during gameplay. Such results echoed with the literature that students are likely to demonstrate inefficient behaviors due to the high cognitive load in a digital learning environment (Kirschner, Sweller, & Clark, 2006). The key design challenge we confirmed here is that children are difficult to distill abstract knowledge out of their learning experience with high cognitive load (Mulder, Bollen, de Jeong, & Lazonder, 2016). Therefore, demonstrating knowledge and skill transfer across contexts can be challenging. Therefore, it is essential to present a learning support that reminds children of what certain blocks and their combinations they can experiment with further. Further regression analysis also highlights the importance of evaluation- and prediction-related actions in gameplay.

The Role of Parents in the Development of Youths' Interest in an Engineering Workshop

Lillyanna Faimon, Penn State University, lkf5240@psu.edu
Heather Toomey Zimmerman, Penn State University, heather@psu.edu

Abstract: Parents support and facilitate youths' interest in informal education settings; however, this has not been fully explored in all informal contexts. We investigate how family interactions influence youth interest during an informal engineering workshop, analyzing one family's interactions using video-based ethnomethodology. Findings show that parents help facilitate the development of situational interest and further sustained involvement by bringing in new information and encouraging participation through connecting interests to the workshop.

Youths' exploration of the world around them is supported and influenced by the adults in their lives. Family inquiry practices including jointly orienting to a problem and using sensemaking resources can engage children's learning and interest in inquiry (Keifert & Stevens, 2019). Within informal settings, such as museums, workshops, or homes, parents scaffold children's learning and inquiry through conversational techniques (Benjamin, Haden & Wilkerson, 2010) and explanations (Fender & Crowley, 2007). They also encourage, support, and facilitate children's interest through gesture, conversation connecting to learning activities, scaffolding intake of new information, and engaging in familiar social practices (Zimmerman, Perin & Bell, 2010). Children's interests can be a) continuous interest that the parents build upon both in and outside of specific settings or b) situational interest, which is a spike in interest triggered by the context and the child's engagement. Situational interest is discontinuous and novel for the child, but it is based on previous continuous activities or interests (Azevedo, 2017). The maker movement offers a way to engage in interest-driven learning through the creative production and sharing of artifacts (Halverson & Peppler, 2018). However, parental involvement in encouraging situational interest has not been fully studied in all informal contexts (e.g., facilitated maker workshops). Therefore, this study focuses on analyzing how parent's interactions with their children impact their situational interest and engagement with the project or problem in an engineering maker workshop.

Methods

This study centers on a one hour-long workshop focusing on engaging families with elementary aged children in engineering principles using littleBits in a nature center that took place as the second iteration of a larger Design Based Research project called *STEM Pillars*. The workshop was organized around the guiding question: "How do engineers solve problems?" and the Engineering is Elementary model of Ask-Imagine-Plan-Create-Improve-Share (Cunningham, 2009). The families investigated littleBits (modular electronics) through open-ended exploration, simple problems (i.e., tickler, auto greeter, flashlight, flickering lantern), and a challenge problem (i.e., helping neighbors who could not see well). Throughout the workshop families shared their inventions with the other attendees and the STEM expert facilitator. A team of researchers collected video and audio data (5 hours of video; 4 hours of audio) and field notes. Out of the seven families (10 adults, 8 children: ages 6-10) that attended the workshop, we focus on one focal family, Lawrence (age 6) and his father Jax, because of their strong interactions and engagement throughout the workshop.

We analyzed the recordings using ethnomethodology (Koschmann, Stahl & Zemel, 2007). Through this analysis, we identified key moments for further analysis by focusing on the family interactions that influenced youth engagement in the workshop present within the videos and content logs. The clips were transcribed and analyzed through group and individual viewing sessions.

Findings

Situational interest (Azevedo, 2017) is driven by environmental factors, both by the context and by the interactions between participants. The activities and interactions of Lawrence and his father illustrate how situational interest can be triggered and encouraged by parental involvement—bringing in new information from materials, prompts, or explanations and supporting children's interests through conversation and gesture (Zimmerman et al., 2010). Lawrence's situational interest in engineering practices was triggered by creating an invention with his father to answer the prompt: "Help your neighbors who cannot see well – elderly people, young children or people with disabilities". Jax translated this prompt it into a sample goal connected to Lawrence's interests that he could work toward: bringing in new information (*"They need an alarm, that gives a sound, when someone enters the room"*). Based on this goal Lawrence had the idea to have the lights act as an alarm, animatedly gesturing to his glasses and eyes when explaining how to make the light *"go in their eyes better"*. This, in turn, inspired Jax who used gesture to explain his idea to have the light attached to the person's glasses. As they placed the littleBit light onto Lawrence's glasses, Lawrence's facial expressions and body language indicated excitement, showcasing his triggered situational interest, which was enhanced by his father's interactions.

Situational interest is both discontinuous, sparked by something in the environment, and continuous, based on previous continuous activities and interests (Azevedo, 2017). Lawrence began the workshop interested in inventing, supported by his father's engagement with both the questions the expert posed and with Lawrence's ideas. His continuous interest was encouraged through his father's explanations of the mechanics and electricity behind the functionality of the littleBits as they explored. In one episode, after Jax stated that they invented a fan, Lawrence asked *"How?"*. Throughout Jax's explanation Lawrence followed up, engaging with gesture and touch—pointing to parts of the invention they were discussing to further illustrate the electricity following through it. Jax helped to encourage Lawrence's engagement and interest in inventing while connecting their inventions to the bigger concept of electricity. This continuous engagement helped support Lawrence's later situational interest that was sparked by his and his father's eyeglasses light invention.

After situational interest was sparked, it appeared in future interactions in different forms (Azevedo, 2017). This can be seen in the ways that Lawrence interacts with his invention through engineering processes like sharing and iterating, and how his father influences this interest. When Jax encouraged Lawrence to share his invention with everyone, Lawrence's gestures and facial expressions indicated that he was excited, yet he hesitated several times once standing up to share, even saying that Jax should be the one to explain the invention. Jax reiterated that Lawrence should share the invention, but he comes up with Lawrence and offers his support through the whispered words *"I'm here*" and placing his arm unobtrusively on Lawrence's side to indicate his presense while not undermining his son's authority. This supported Lawrence to share his invention with confidence. After sharing, Lawrence's interests in refining and iterating on his invention continued. He asked questions and posed alternate scenarios to puzzle out how to make the invention better. Later in the workshop, he asked *"But what if they hold it not onto the doorknob? And just opened it up by the door if it opened like back in?"*, troubleshooting the use of a pressure sensor placed on the doorknob. He and his father experimented with a light sensor, exploring its functionality with and without the pressure sensor also attached to the invention to refine their invention. Lawrence's continued engagement with his invention illustrated how situational interests develop after they are triggered and how continued engagement is influenced by parental involvement.

Conclusion

The case study of Lawrence and Jax during an hour-long engineering workshop illustrated how situational interest (Azevedo, 2017) can be supported through parents bringing in new information around workshop activities and guiding participation by connecting interest to the workshop goals (Zimmerman, Perin & Bell, 2010). Lawrence's interest in engineering processes used in creating an invention that allowed people who could not see well to know when someone was coming in the room was aided by his father's support before, during and after the event that triggered this situational interest. The implications of these findings are key in designing environments where parents are supported to encourage children's interest in STEM in various informal learning contexts.

Transformative Learning Technologies Lab

Abstract: Maker education stands out as an approach to STEM learning that has several benefits. However, despite the recent rise in its popularity, making in education may be excluding some groups of learners. In this poster, we report partial findings of a mixed-methods research project carried out in two high schools serving blue-collar, working-class families in Southern Brazil. We find that factors associated with shifts in self-reported attitude towards STEM and self-efficacy in engineering differ across genders.

Introduction

Maker education has recently undergone major growth in popularity and has become a global phenomenon in education. Scholars in maker education claim that this approach to STEM learning could lead to empowerment and emancipation (Blikstein, 2008), foster critical thinking (Kafai & Peppler, 2014), and engage kids in powerful learning (Halverson & Sheridan, 2014). Despite the rise in popularity, however, we know that maker education is not evenly distributed across regions, social classes, and demographics. Additionally, the themes explored by maker activities in school settings may not cater to all. Therefore, some groups of students may be excluded from learning environments that promote those practices. It is known, for example, that learners from different genders and social, economic, and racial groups are underrepresented in maker environments, such as maker faires and fabrication labs (Holbert, 2016).

In order to investigate gaps that hinder the achievement of equitable maker education, we conducted an investigation in Southern Brazil. In this paper, we report partial findings of a study conducted in two tuition-free schools serving families of blue-collar workers, run by a non-profit institution. *Since the project is ongoing, and due to the nature of a poster, here we focus on survey data, although the data set also includes in-depth interviews with teachers and students -- we are aware, however, of the limitations of data collected via surveys.* The data analysis reported here seeks to shed light on the differences and similarities between male and female students in terms of their self-efficacy in engineering and attitude towards STEM. Responses were analyzed in search of patterns that help explain variances (and lack thereof) in those attributes across genders in students.

Methods

242 high school students answered an online survey based on validated instruments (Siegel & Ranney, 2003; Wang & Berlin, 2010). It contained open-ended, multiple-choice, and multiple-answer questions, and also collected students' names. 140 respondents were female, 101 were male, and 1 preferred not to say their gender; 90 students were in the 10th grade, 77 in the 11th, and 75 in 12th grade. The questionnaire had 7 sections, of which 3 are relevant in this work:

- Dimensions of interest: ***Self-efficacy (engineering)***: A section containing 10 items. ***Attitude towards STEM***: A section with 16 items. Both were composed of Likert-scale items ("Strongly disagree" -- "Strongly agree"), which were recoded to a 1-4 scale.
- General information: ***Gender***: students were given 4 options: "Female," "Male," "Other," and "Prefer not to Say." ***Frequency of classes at the makerspace***: the frequency ranged from "less than once a week" to "more than 5 times a week." ***Frequency of experiments or hands-on projects in STEM classes***: the frequency ranged from "never or almost never" to "every day or almost every day." Data from this section were used to analyze the dimensions of interest.

Results

We ran factor analyses (Grice, 2001) to model non-observed variables of interest for the dimensions of interest. Due to the ordinal nature of these variables, we used polychoric correlation matrices to predict regression scores for each respondent in each of the factors. Then, we ran statistical tests to compare the predicted scores between genders. For the factors whose distributions did not follow normality, we ran Mann-Whitney-Wilcoxon (MWW) two-sample tests. Otherwise, we ran t-tests. Then, again due to the shapes of distributions, we ran MWW tests to analyze how predicted factor scores differ within each gender according to the two frequency scales.

Factors obtained through factor analysis

Self-efficacy (engineering): 1) SEE: Designing, making, and constructing (range of predicted scores: -3.23 -- 1.79); 2) SEE: Tackling difficult problems (range of predicted scores: -2.91 -- 2.01); SEE: Active invention and fixing (range of predicted scores: 2.37 -- 2.02). ***Attitude towards STEM:*** 1) ATS: Learning through designing, developing, and building (range of predicted scores: 2.79 -- 1.49); ATS: Feeling good at school (range of predicted scores: -3.41 -- 1.21); ATS: Learning with new materials (range of predicted scores: -2.69 -- 2.26).

Comparing the factors across genders

Our analysis shows that there was no statistically significant difference between female and male students in any of the 6 factors that make up "Self-efficacy (Engineering)" and "Attitude Towards STEM."

Comparing factors of self-efficacy (engineering) and attitude towards STEM among male students, according to the frequency of classes at the makerspace

Variation in "active invention and fixing" among boys: A one-sided t-test showed that *there is a statistically significant difference* in the predicted score for this factor between boys with a low and those with a high frequency of classes at the makerspace ($M = -0.17$, $SD = 0.92$; $M = 0.23$, $SD = 0.94$, respectively); $t(80.406) = -2.38$, $p = 0.023$. ***Variation in "feeling good at school" among boys***: A MWW test indicates that *there is a statistically significant difference* in this factor between boys with a low and those with a high frequency of classes at the makerspace (Mdn = -0.74 and Mdn = 0.51, respectively), $U = 655$, $p = 0.007$.

Comparing factors of self-efficacy (engineering) and attitude towards STEM among female students, according to the frequency of experiments or hands-on projects

Variation in "tackling difficult problems" among girls*:* Through the MWW test we found a *statistically significant difference* in this factor between girls with a low and those with a high frequency of experiments or hands-on projects (Mdn = -0.78 and Mdn = 0.34, respectively), $U = 1135$, $p = 0.013$. ***Variation in "feeling good at school" among girls***: The MWW test indicates that there is a *statistically significant difference* between girls with a low and girls with a high frequency of experiments or hands-on projects (Mdn = -0.60 and Mdn = 0.59, respectively), $U = 937.5$, $p = 0.001$.

Discussion and conclusion

In contrast to what is commonly seen in the literature, in this context in Brazil female and male students report similar attitudes towards STEM and self-efficacy in engineering. Nonetheless, a closer look at the components of the school experience for these students reveals that the frequency of classes at the makerspace is associated with differences among male students, and the same is true with the frequency of experiments and hands-on projects among female students. In summary, the data suggest that simply being present in makerspaces is not enough to promote meaningful learning and a sense of belonging in STEM for female students -- a finding that might apply to other minoritized groups. In the future, we plan to further triangulate qualitative data (interviews with students and teachers) to investigate the causes that contributed to the results reported in this paper.

Abstract: Leveraging Dilemmas as a Pedagogical Tool for Novice Youth Worker Learning

Erica Van Steenis, University of California, Irvine, erica.vansteenis@uci.edu

Introduction

Efforts to professionally develop youth workers, educators who play an essential role in the social, emotional, and academic development of youth in afterschool contexts (Fusco & Gannett, 2012; Pozzoboni & Kirshner, 2016), often depend on explicit skill development. Explicit knowledge and skills include, for example, that youth workers understand the principles of child and youth development and apply them, that they use positive guidance techniques to manage the behavior of youth, and that they build relationships with families and other organizations in the community that encourage support of and involvement in the program. The field's articulation of standards is useful, but a focus on explicit skill development tends to minimize an important and necessary focus of on-the-job professional development and runs the risk of reducing youth worker expertise to a rote and procedural set of requirements. The field's efforts to design youth worker development around a standardized vision of explicit knowledge and skills has met with limited success. The tension is that much of youth worker learning typically occurs on the job as part of a learning process of implicit know-how through practice and reflection (Polanyi, 1966; Taylor, 2007).

The central argument I hope to advance via this poster presentation is that the field would do well to move from youth the focus on explicit skill development to embrace the complex ecosystems in which learning occurs (Gutiérrez & Jurow, 2016). This reasoning builds from the idea that the field's articulation of standards has perpetuated a vision of youth work as uncomplicated, making implicit knowledge and skill development for novice youth workers less transparent and difficult to articulate. As a corollary, robust pedagogical designs for youth worker teaching and learning to prepare practitioners for their on-the-job realities tend to be underdeveloped. While some practitioners may possess the necessary personal and transferable attributes important to the profession, most youth workers learn experientially throughout their time in-service as they gain the skills and knowledge necessary to navigate the complexities of the career. Therefore, explicit professional development frameworks need to be augmented by research that captures how to become a youth worker and novices' process of learning and development.

To begin arguing these points, I consider one locus of youth worker learning that is less articulated and researched: implicit skills (Polanyi, 1966; Taylor, 2007) developed experientially as youth workers navigate complex dilemmas of practice (Walker & Larson, 2012; Ross, 2013). I contend that dilemmas of practice ought to be leveraged at the higher education level in particular to build a pedagogical framework from which to teach novice youth workers implicit skills of the profession. I analyze novice youth workers' experience and reflection on dilemmas of practice that they faced as part of an experiential course called Adolescent Development and Educational Psychology (ADEP).

ADEP course design

ADEP was a higher education course that drew on positive youth development and experiential learning in afterschool youth programs. This course intentionally designed a curricular approach around dilemmas of practice, combining instruction about youth development theory, volunteer experiences in youth programs, and the practice of field noting. The course was organized the course around two driving questions:

1. How can adults build a developmental alliance with a young person that embodies elements of positive relationships identified in research?
2. How should classroom and community settings be designed so that they engage and empower young people?

We aimed to develop students' social justice awareness by attending to how adolescents' experiences in settings vary across lines of race, class, gender, citizenship status, language, and sexual orientation. The course leveraged experiential learning opportunities as students volunteered in local youth programs. The instructor team envisioned that through field experiences the students would develop self-awareness, as well as knowledge about adolescent development, which would enable them to reflect on their own approaches to situations and their narratives about youth and programming.

Sources of data and research questions

I collected the data presented in this poster between 2014-2018. For the broader study, I employed a qualitative analytical approach, collecting novice youth worker field notes, and eventually narrowing to case studies. In this poster, I present what four novice youth workers, Sydney, Connie, Claire, and Michael, learned in their experience with *dilemmas of practice*. They each wrote 3-5 sets of field notes representing what they defined as significant interactions throughout the semester.

Findings

In the poster, I will present the four case studies of Sydney, Connie, Claire, and Michael, four ADEP students. The analysis of the cases advances three claims. First, dilemmas faced in the field draw out tensions that exist for novice youth workers. Second, dilemmas orient and reorient the practitioner, encouraging new mental models to arise for approaching a problem of practice. Third, dilemmas advance the implicit skills of youth worker practice, including flexible and adaptable approaches and recognition of one's own socially and historically constructed stance on a situation. The use of dilemmas as a pedagogical strategy in ADEP revealed the ways in which novice youth workers struggled to resolve how to bring their identities and values, conceptual approaches to youth work, and situational encounters into concert with each other. Experienced youth workers, those who have spent much time in the field and with dilemmas, possess mental models for working these dimensions to approach dilemmas flexibly. These youth workers had to travel a path toward learning those implicit skills as they navigated their dilemma even when they felt ideologically opposed to or challenged by at first. Situating this pedagogical approach in a course, especially through writing field notes and engaging in critical reflection, shaped student learning and enabled students to make sense of situations that professionals in the field face.

I found that these cases offer useful takeaways for a field with few studies of pre-service education for youth workers, including:

1. The case studies illuminate how dilemmas can be used as a key pedagogical tool for novice youth worker learning.
2. Dilemmas illicit conversations about and practice with adaptive problem solving.
3. Dilemmas enabled students to make sense of situations that professionals in the field may face and how to do so while also leveraging equity-oriented approaches to youth work.

This work presents two versions of a series of conceptual puzzles situated within a video game for introducing players to the field of cybersecurity. Using players' gameplay experiences, we discuss how players' interaction with the first version of puzzles informed the design of game mechanics in the second version. We present the changes made in the second version and how the revisions helped turn unproductive frustration into productive frustration, which improved the gameplay experience. The findings show poorly designed puzzles create unproductive frustration, which inhibits the gameplay and learning experience; whereas well-designed puzzles create productive frustration, which supports players in learning.

This work builds upon the design of an under-development educational videogame, *Hex of the Turtle Islands* - an adventure game, which mixes explorative gameplay with more traditional puzzles. Our game design goal is to introduce players to the field of cybersecurity and to help them develop an identity of someone who can succeed in the field of cybersecurity. Using a design-based research (DBR) approach with a focus on designing conceptual puzzles (Barab & Squire, 2004), we utilize iterative rounds of development and feedback as a means to understand if and how the game is meeting our goals. In this work, we investigate the different players experiences with two versions of the game and how revisions of in-game puzzles contribute to shifts from unproductive frustration to productive frustration.

Puzzles are a crucial component in a wide variety of game genres as they provide opportunities for players to problem solve, explore, and use their previous experiences as a means of constructing knowledge for their next action (Juul, 2008; Oei & Patterson, 2014; Bonner, M. 2016). Our analysis focuses on learning as a generalizing activity (Ellis, 2007). We specially emphasize failure within learning videogames (Gee, 2003; Litts, & Ramirez, 2014). Failure paired with feedback can result in productive frustration that leads to productive iterative action-reflection cycles for the learner (Shokeen et. al., 2020).

In the data collection, we tested the initial game design ideas with 11 participants to understand how players respond to the game. The findings from the first version of game were used to iterate the design. The updated version of the game was tested with another set of 9 participants. Participants ages ranged from 10 to 15.

Version 1: Initial design of the wire puzzle

The wire puzzle is a logic puzzle that presents the player with a set of rules that must be followed for connecting wires to the appropriate ports. Players must follow a series of rules shown in the Wire Library (Figure 1, Label **A**) to solve the wire puzzles (Figure 1). The player must produce a correct configuration by dragging wires from label **B** to **C**. The interface tells the player how many wire connections are needed (Label **F)** and tracks their progress as the players proceed through the puzzle (Label **D)**. The Error Log (Figure 1 - Label **E**) provides feedback highlighting errors in the connection on failed attempt.

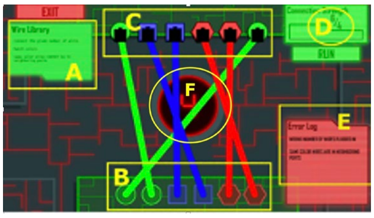

Figure 1. Wire Puzzle

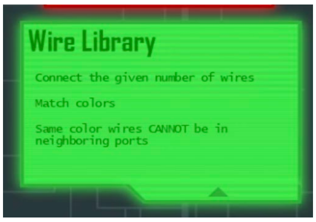

Figure 2. Version 1 Library

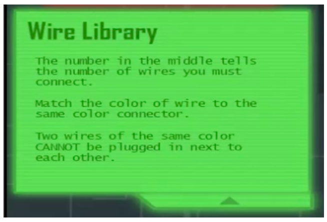

Figure 3. Version 2 Library

During the first puzzle version most of the players in their first attempt connected all the wires but struggled with the information provided in the puzzle interface and reached out to researchers seeking external feedback on their repeated failures i.e. unproductive frustration. These were struggles found mainly due to confusing wording of Wire Library (Figure 2). These findings identified places where design changes were needed, so we addressed these issues in the second design version.

Version 2: Revised design of wire puzzle

The major change to the wire puzzle for the second version was the introduction of 'wire modules', which are in-game representations of the rules associated with the puzzle and the re-wording of Wire Library rules (Figure 3). Players have to find the wire modules scattered around the island that prepare the player to expect a puzzle based on those modules. In the second version, all players were challenged by the wire puzzle. However, they were able to solve the puzzle successfully without seeking external feedback, which shows evidence of a productive frustrating experience.

Determining when the design does not provide accessible feedback to support learners who are failing is a crucial part of DBR. Identifying moments of unproductive frustration can show where modifications of the puzzles in the game are needed to better support iterative action-reflection cycles by players. We found a range of differences between players' experiences during the data analysis of play sessions from the first version of the game. We were then able to use the identified moments of unproductive frustration to design better paired failure-feedback by both communicating rules more clearly up front, and also changing language to be more accessible in both the rules and the feedback mechanism (e.g., the wire library and the error log). These mechanics served to support persistence through productive frustration, which resulted in fewer moments of unproductive frustration by players in the second version of the game. This speaks to one of the challenges of designing learning games: balancing the need for sufficient challenge for the game to be engaging, while ensuring that players are sufficiently supported in learning from and completing those challenges. Informing game design based on productive frustration and unproductive frustration can support designers and researchers in identifying when the challenges and supports are insufficiently balanced. Too many unproductive frustration occurrences indicate that failure and accompanying feedback need to be revised. Through DBR, we found that players experienced an appropriate amount of productive frustration, allowing them to engage in iterative action-reflection cycles.

Feedback and failure play a pivotal role in determining whether a player is experiencing productive or unproductive frustration while solving in-game puzzles. We leveraged moments of unproductive frustration in gameplay sessions of our first game version to guide our redesign and focused particularly on redesigning the feedback and failure mechanics. In developing the idea of productive and unproductive frustration as an analytic lens to be used in the evaluation and design of game-based learning environments, we seek to add another analytic tool to the educational game designers' toolbelt. In doing so, we help equip designers to make engaging and effective game-based learning environments.

Abstract: This meta-analysis includes 143 empirical studies and investigates the effectiveness of different strategies to adapt and individualize instructional support to learners' prior knowledge and performance within simulation-based learning environments. The review identified strategies effective for learners with lower and higher prior knowledge and contributes to the discussion about effective design of learning with simulations. We conclude that (1) adapted instructional support enhances effects of simulations; (2) different strategies of adapting are effective for learners with different levels of prior knowledge.

Problem statement

Empirical research provides supportive evidence on the effectiveness of learning with simulations in different domains of higher education (e.g. Chernikova et al., 2020, Theelen et al., 2019). However, the research also shows that there is no single solution for effective instructional support which would fit all the learners. This paper contributes to deeper theoretical understanding of instructional support and learning, and provides valuable insights for practitioners and policy makers.

Theoretical background and research questions

The current meta-analysis aims at identifying the added value of adaption strategies for learners with low and high prior professional knowledge. This paper is grounded in skill development theories (e.g. Van Lehn, 1996) and empirical research on scaffolding and other instructional support measures, which were found to be beneficial in early stages of skill development, when learners are exposed to complex problems (e.g. Hmelo-Silver et al, 2006).

To capture adaptivity of learning environments we rely on the framework suggested by Plass & Pawar (2020). Under strategy of adapting we understand decisions made by educators, which were implemented and described in the primary studies.

The following research questions were addressed in the paper. (RQ1) In what ways strategies of adaptation are implemented in simulation-based learning environments in higher education? (RQ2) To what extent can these strategies facilitate learning outcomes in learners with higher and lower levels of prior knowledge within simulation-based learning environments in higher education?

Methods and results

The analysis is based on the collection of primary studies and average effects reported in a meta-analysis by Chernikova et al (2020), and is focusing on the added value of instructional support within simulation-based learning environments. A random-effects model and Hedges g estimation were used (Borenstein et al, 2009).

The average effect of simulations on learning was found to be g=.85, SE =.08 (Chernikova et al., 2020). This effect was used as a reference point to estimate the effectiveness of each adapting strategy.

The following adapting strategies (RQ1) were identified in the studies implementing simulations in higher education: (1) fixed adaptation based on the pre-test, (2) adaptation based on performance during simulation, (3) giving participants control over amount of support. The amount of studies implementing these strategies is reported in Table 1.

In regard to RQ2 we were able to identify one strategy, which was beneficial for all learners, a strategy that had some positive tendency for learners with a high level of prior knowledge, but was rather disadvantageous for students with low levels, and a strategy that had positive effects for learners with low prior knowledge and tended to limit learning gain for learners with high prior knowledge. Number of primary studies, effects sizes and standard errors are presented in Table 1.

Discussion

The findings of the current meta-analysis reveal that in simulation-based learning environments learners benefit from the opportunity to decide on the amount and timing of instructional support they get – this stands in some contrast to effects reported a range of more traditional learning environments (cf. Belland et al., 2017). Our findings suggest that within simulation-based learning environments different strategies of adapting are effective for learners with different levels of prior knowledge.

The limitations of this study include (1) a relatively coarse-grained categorization of strategies to adapt instructional support which might be confounded with some implicit instructional support within the simulation-based learning environments; (2) very scarce the description of learning environment in primary studies and (3) focus on only objective measures of learning outcomes.

In conclusion, as hypothesized, the effects of simulations can be enhanced by instructional support measures and adapting the instruction to match learning needs leads to higher learning gains. More research is needed directly comparing different adapting strategies for instructional support to fully exploit the power of simulations in developing complex skills.

Table 1: Effectiveness of adapting strategies

Strategy		**Low prior knowledge**	**High prior knowledge**
Fixed adaptation (based on pre-test)		*N* , Hedges *g* , (*SE*)	*N* , Hedges *g* , (*SE*)
Treatment	used	*N* =1, na	*N* =0, na
	not used	*N*= 56, .81 (.13)	*N*= 59, 1.08 (.11)

Investigating Student Engagement through a Virtual Reality Classroom

Noah Glaser, University of Connecticut, noah.glaser@uconn.edu
Ido Davidesco, University of Connecticut, ido.davidesco@uconn.edu
Elana Zion Golumbic, Bar Ilan University, elana.zion-golumbic@biu.ac.il

Abstract: We present a prototype of a Virtual Reality classroom that is designed to investigate students' engagement as they interact with student- and teacher-avatars, multimedia presentations, and environmental cues. Student engagement is assessed by triangulating multiple measures, including self-reported data, system trace data, electroencephalography (EEG) brain data, and eye tracking.

Keywords: virtual reality, online learning, student engagement

Background

Student engagement is a complex, multidimensional construct that is typically viewed as incorporating affective, cognitive, behavioral, and social components and is thought to be an important pathway between instruction and learning (D'Mello et al., 2017). Due to its multidimensional nature, student engagement is difficult to operationalize and measure. Assessing student engagement is even more challenging in online environments, where information about students' behavior (e.g., nodding, taking notes) is very limited. Advances in virtual reality (VR) technologies now make it possible to examine student engagement in an authentic context with experimental manipulation of the learning environment (Glaser & Schmidt, 2018). Further, VR allows for the study of complex and intricate phenomena (in this case, engagement) within replicable scenarios (Bailenson et al., 2008). VR refers to a three-dimensional, computer simulated environment experienced by users via specialized equipment such as tracking systems and head-mounted displays (HMD) that mediate one's interactions within the digital environment. The use of VR HMDs also provides the additional affordance of promoting a user's sense of telepresence (i.e., feelings of immersion and sense of presence; Bailenson et al., 2008) and enabling users to embody their actions and social interactions to construct an online identity (Dalgarno & Lee, 2010). Users of VR learning systems are represented by avatars that act as the nexus for engagement as they interact with and have their actions mirrored into the world around them and with other users through scripted events that serve as instructional objects and outcomes. An additional affordance of this technology is the benefit of automating data logging (trace data) to provide a holistic snapshot of student–computer, student-student, and student-teacher interaction in the virtual world (Glaser & Schmidt, 2018). These trace data can be further coupled with physiological data, such as eye tracking and Electroencephalography (EEG), to further glean insights into the nature of student behavior within virtual learning environments (Yang et al., 2019).Yet, several challenges should be considered in the context of using VR in learning sciences research. Beyond the more apparent limitations related to the cost and resources required to develop such software, not much is known about the perception of instructional content and multimedia within 3D virtual learning environments (Sutcliffe et al., 2019). There are also concerns related to adverse effects such as cybersickness that some individuals experience while using VR (Davis et al., 2014)

Proposed VR classroom

Here, we present a prototype of a VR classroom, where students control an avatar and receive instructional content delivered by a teacher-agent avatar. The strength of the VR classroom is that it allows simulating real-world learning in the lab, while researchers maintain full control over the learning environment, and can manipulate it to test specific hypotheses. As such, it provides an excellent intermediate tool for bridging between controlled lab-based research and real-world classroom research. Whereas previous attempts to use VR classrooms have focused on attention-deficit/hyperactivity disorder (ADHD) assessment with highly artificial tasks (e.g., identifying a target letter in a sequence of letters) (Parsons et al., 2007), our VR classroom allows investigating student engagement with authentic learning tasks that can evolve in complexity. The system also supports the collection of self-reported data, eye gaze, and EEG brain activity (Fig. 1). In recent years, there has been growing interest in a variety of physiological measures that may supply more direct means for assessing student engagement (D'Mello et al., 2017). Whereas eye tracking can provide important information on how students engage with the virtual classroom environment as they shift their gaze between different elements (e.g., from the teacher to other students), EEG can provide information about *covert* shifts of attention during periods of steady eye-gaze (e.g., students might be staring at the teacher while thinking about their weekend plans).

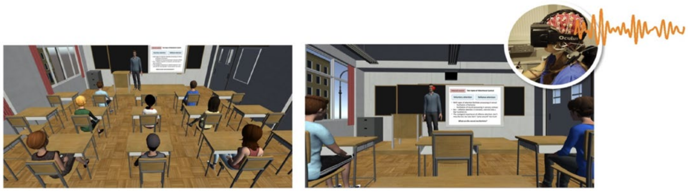

Figure 1. The VR Classroom (inset: a participant wearing an HMD with built-in eye tracker over an EEG cap).

Due to the COVID-19 pandemic, we have not yet been able to collect experimental data with the VR classroom. Instead, we will discuss the type of research areas that can be addressed with the VR classroom environment. For example, using the VR classroom researchers can investigate the interaction between the type of instruction, level of distractors, and student engagement. In other words, at what level of distractors do students become disengaged and does that depend on the type of instruction (e.g., listening to a lecture vs. solving a problem)? Whereas in a real-world classroom, it is hard to manipulate distractors experimentally, in the VR classroom, researchers can introduce and vary the level of distractors, such as a siren of an ambulance passing by and student conversations. Furthermore, the VR classroom offers high fidelity as the learning scenarios are pre-programmed and applied consistently across students. By using this approach, we can seek to examine content and pedagogy types with the goal of identifying how the individualized needs of learners can best be met in online learning spaces. Varying degrees of interaction by the user and within the environment itself can also be designed to examine how the features of the system can promote attention and learning outcomes. The VR classroom also allows to address questions related to how students experience the environment itself, such as to what extent do students experience telepresence, how the features in the environment foster engagement, and whether they experience any adverse feelings (e.g., cybersickness). This line of inquiry has direct implications to the learning sciences as research suggests that these feelings can impact students' sense of presence, cognitive load, usability, flow, engagement, and satisfaction (Servotte et al., 2020). We believe that our findings will have broad implications to the learning sciences, instructional design, and beyond. At the conference, we will seek to engage attendees in discussions related to the feasibility of our approach, methods of collecting data concerning engagement, and the design of different kinds of pedagogy within a VR classroom.

Exploring University Students' Ecologies of Digital Resources in the Context of Disciplinary Learning

Lise Toft Henriksen, Dan Uehara, Crina Damsa
l.t.henriksen@iped.uio.no, danue@jus.uio.no, crina.damsa@iped.uio.no
University of Oslo, Norway

Abstract: This contribution explores university students' use of digital technologies for learning purposes and distinguishes between technologies provided by their institution and external technologies students accessed on their own. Participants were university students, surveyed and interviewed about use of and experiences with various digital technologies. The findings show a pattern in the use of institutionally provided and self-accessed technologies, and that students themselves generate value from their interaction with these technologies.

Introduction

This contribution explores undergraduate students 'use digital technologies for learning, under the assumption that learning involving curricular resources is often combined with activities crossing the boundaries of formal education, especially into online contexts. Students may follow less structured and unorganized pathways as they engage with online resources, such as social media and experience- and resource-sharing tools. Networked digital technologies have undoubtedly transformed the ways in which learning takes place, and the potential to 'support', 'enable', or 'enhance' learning has been associated with every significant development in digital technology (Veletsianos & Navarrete, 2012). New technologies are widely seen to support students in co-creating knowledge with peers, engagement in interest-driven informal learning practices, or personalized engagement with education. Still, concerns remain over the realities of digital technology use within university teaching and learning (Selwyn et al., 2016). Research in this area examined the implementation of different web 2.0 technologies, such as wikis, blogs or Facebook groups, and their effects on student learning and engagement (Heimbuch et al., 2018). Findings are varying and often contradictory, highlighting both opportunities and challenges.

Following Selwyn and colleagues' (2016) argument, this study offers a view of university technology use that is 'state of the actual' rather than 'state of the art' and an exploration of the everyday uses of digital technology by the students in practice. Against this backdrop, the purpose of this study is to contribute to a research agenda that aims at making the students' ecology of resources (Luckin, 2008) explicit, by understanding both use and the distinction between institutionally provided digital tools and digital tools students access and use on their own initiative. With this in mind, the study will answer the following research questions: 1) *What digital technologies are students using for studying and learning?*, 2) *What are the relationship between digital technologies and study programs?*, and 3) *What are the purposes and key drivers for students to adopt different types of technologies for learning within and beyond the university 'ecology'?*

Methodology

The data set was collected at a Norwegian university. A mixed-methods exploratory study was set up to map and interpret students' use of digital technologies related to their study- and learning activities. A survey was applied to 154 students from four study programs [Informatics (INF; n = 35), Philosophy (PHIL; n = 18), Educational Sciences (PED; n = 69) and Humanities/language course (TEd; n = 32)]. The specific items investigated was "What digital channels and tools do you use, and how much?" with responses "Used a lot", "Barely Used" and "Never Used". In addition, a focus-group interview was organized with four students (INF, PHIL, PED, and HUM) focusing on the students' own experiences with use of technology. The (ongoing) analysis consisted of descriptive statistics, independence tests (Cochrane-Armitage test) and an association measure (Freeman's Theta) of the survey data. The qualitative interview data was analyzed following a thematic analysis approach (Braun and Clarke, 2006). We present the quantitative findings in table 1 and the qualitative findings using illustrative data extracts.

Findings

Nearly all student students across all study programs used Canvas (Table 1). There was a low but statistically significant association between Canvas use and the four study programs. Eighty-three percent of students used Instant messaging platforms (IMPs). There were equal proportions of students across all our programs that used IMP, which was indicated by an insignificant association test (Table 1). Finally, a high proportion of students used Wikis with 58% of PHIL and 57% of INF students using Wikis "frequently". The association of use of Wikis by discipline was statistically significant but low (Table 1).

Table 1: Quantitative results

	Whole Sample				Study Programs	
Tools	**Prop. (SD)**	**(3) %**	**(2) %**	**(1) %**	**χ^2 Test (df; p)**	**θ_F (CI_low; CI_high)**
Canvas	0.96 (0.11)	62	34	4	15.94 (3; 0.00)	0.23 (0.13, 0.35)
IMP	0.83 (0.38)	69	15	18	6.19 (3; 0.10)	NA
Wikis	0.84 (0.36)	41	44	16	10.63 (3; 0.01)	0.22 (0.12, 0.36)

Notes. SD = standard deviation; (3) = "Used a lot"; (2) = "Rarely used"; (1) = "Never used";
χ^2 = Chi-square; df = degrees of freedom; p = p-value θ_F = Freeman Theta

Findings from the focus-group interview. **Within the university 'ecology':** ***Canvas***. Students reported that, although Canvas is the official LMS in use at the university, the *usage* is limited. One student explains: *"I mainly [...] look at things my professor says s/he put up there." (PHIL).* Canvas is predominantly experienced as a management tool. However, students also see a potential in Canvas as a tool for supporting learning processes, for example, when *"the teacher puts out a lot of discussion questions" (PHIL)* which have *"been helpful to me" (HUM).* **Beyond the university 'ecology':** ***Instant messaging platforms (IM).*** Facebook/messenger is referred to as the most commonly used communication infrastructure. It is, among others, used for organizing study groups, and for group discussions: "*To get a better idea of what we have learned" (HUM)*. One student (PHIL) explains that social media might be used as the main way to communicate since the students are already using it for social purposes. This makes Facebook "*not that organised"* and *"that's kind of a challenge" (PHIL).* ***Wikis.*** The students frequently use Google Search; however, their experiences with "google-ing" differ. "Google-ing" can, for example, lead to specific Wikis, that: *"Gives, like, a nice summary and then I'll know, I'll recognize it" (HUM).* For other students, just "goole-ing stuff" becomes a time-consuming activity with no useful outcome. As one student explains: *"I am struggling knowing what specifically I should search for" (INF).*

Contribution and further steps

This study explored the use of digital technologies by university students from four disciplinary programs. The findings indicate that students use both institutionally-provided and self-accessed technologies to support their study and learning activities. Overall, we see an effort from students to 'customize' the technologies they access and use. This assemblage effort can be justified by instrumental purposes (which technology provides the best support for a certain activity), discipline-related study needs (support for specific activities), and familiarity with certain technologies due to personal use (Selwyn, 2016). While students seem to use technologies that are not institutionally provided in an emergent way, they appear aware of the fact that their use may be unstructured, and therefore, not always productive for their learning. Overall, this study provides empirical knowledge about how ecologies of digital technologies are being assembled by students in emergent or deliberate manner and how these ecologies, and the process of assembling them, may be discipline-dependent. Further research is bound to examine the way students' non-academic engagement with resources and technologies influences academic engagement, and forms of support and guidance for how such ecologies of resources can be assembled in order to provide the necessary mediating for learning.

Designing an Intervention to Foster Teachers' Contingent Responsiveness during Science Discussions

Lydia Y. Cao, University of Cambridge, yc459@cam.ac.uk

Abstract: A teacher's capacity to perceive multiple dimensions of the classroom and to make instructional decisions on the fly is defined as '*Contingent Responsiveness'*. Little is known about how teachers manage the demanding work of moment-to-moment interaction during class discussions and how to prepare science teachers for this challenge. This poster presents the theoretical framework and tentative design features of a professional development (PD) program to foster contingent responsiveness in science teachers.

Introduction

The role of talk in science education has long been established – an essential part of learning science is learning how to engage in scientific discourse (Lemke, 1990). Leading a productive science discussion is challenging - teachers have to respond to the dynamic flow of student talk in the moment, orchestrate different voices towards a collective understanding, support the emergence of new ideas, as well as attend to the complex social relationships among members of the class. Such capacity to attend to multiple dimensions of the classroom situation and the ability to make instructional decisions on the fly in response to student ideas is defined as '*contingent responsiveness*. Despite the breadth of research on dialogic teaching, little is known about how teachers manage the demanding work of moment-to-moment interaction and decision-making on the fly in classroom discourse and how to prepare science teachers for such a challenge. In this study, I co-design a professional development program with teachers in Pakistan to foster contingent responsiveness during dialogic science discussions.

Theoretical framework

Acquiring a repertoire of techniques such as talk moves can help to scaffold a productive dialogue (Kazak et al., 2015). However, research consistently found that whilst teachers are capable of using strategies to elicit student ideas, and to increase students' participation, they often find it difficult in helping students to expand and move their thinking forward (Coffey et al., 2011). Therefore, leading a dialogic science discussion is not simply a superficial elicitation of student ideas, but a sustained interaction for a specific educational goal. Corno(2008) asserted that that teaching responsively is not only technical, but also intellectual as teachers have to simultaneously judge which ideas and questions will be most productive to pursue; attend to the intersection between students' everyday ideas and disciplinary ideas, and channel discussion toward an understanding of disciplinary core (Harris et al., 2012). Nonetheless, what is required of contingent responsiveness is not merely an intellectual exercise with unlimited time for teachers to craft a response, it demands thinking on their feet in a fluctuating array of interactions. The overwhelming pace of a real classroom is illustrated in a one- minute 28-second clip of Professor Deborah Loewenberg Ball, who counted 20 micro-moments when she had to decide how to react (Barshay, 2018). Therefore, responsiveness is not only technical and intellectual, but also improvisational given the fast pace found in a real classroom, which echoes with Sawyer's (2004) metaphor of teaching as an improvisational live performance.

Research aim and method

Given its multifaceted nature and the difficulty in fostering contingent responsiveness, this study aims to understand how science teachers develop such capacity and to design an effective intervention. Using design-based research (DBR) approach, I co-design and iteratively refine a PD program with teachers in Pakistan to foster contingent responsiveness during dialogic science discussions.

Tentative design

The technical, intellectual and improvisational nature of contingent responsiveness is embedded in the design of the intervention. For example, a mixed reality simulator (Mursion: https://www.mursion.com/) is used to address the improvisational nature of contingent responsiveness by approximating the dynamic nature of a classroom and enabling teachers to rehearse teaching in a contextualized environment (Dieker et al., 2014). The talk moves toolkit (Michaels & O'Connor, 2012) addresses the technical nature whilst collaborative inquiry attends to the intellectual nature by promoting conceptual change in teachers, such as the purposes of talk in science. The following conjecture map (Sandoval, 2014) describes the interaction between the design features, mediating process and the intervention outcomes. This poster aims to stimulate a productive discussion around the notion of contingent responsiveness as well as the design features of the intervention.

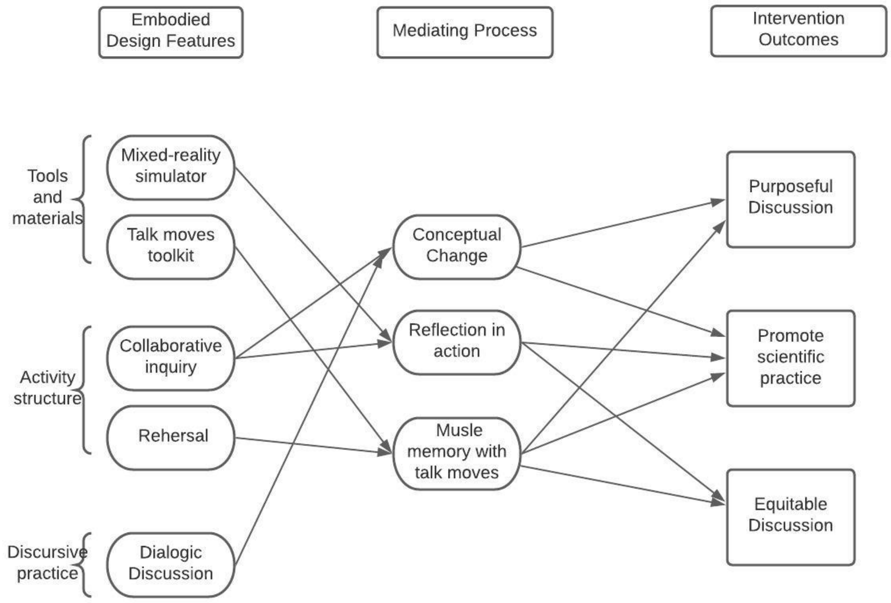

Figure 1. Initial Conjecture Map of the Design to Foster Contingent Responsiveness in Science Teachers.

Linking Talk Types to Socioemotional Formation and Regulation

Nikki G. Lobczowski, Kayley Lyons, Jeffrey A. Greene, Jacqueline E. McLaughlin
nikkilob@cmu.edu, kayley.lyons@monash.edu, jagreene@email.unc.edu, jacqui_mclaughlin@unc.edu
The University of North Carolina at Chapel Hill

Abstract: Social discourse is an important element of collaborative learning. In this study, we qualitatively analyzed the talk types used by groups of graduate pharmacy students during a six-week project-based learning assignment. We found 23 different talk types and linked them to the stages of the Formation and Regulation of Emotions in Collaborative Learning model. The use of different talk types influenced the groups' emotions and overall group functioning.

Introduction

In collaborative learning, students often have difficulty engaging in appropriate discourse with their peers (Bielaczyc et al., 2013), which can result in negative peer interactions and subsequent negative emotions that affect learning and encourage maladaptive collaboration habits (Näykki et al., 2014). The rich literature on discourse includes recommendations on how to engage students in discussions that promote collaboration and learning, as well as how different talk types relate to what and how students discuss (Murphy et al., 2016). Talk types are the different kinds of discourse in which students engage during collaborative learning (Sullivan & Wilson, 2015). More research is needed, though, regarding how different talk types manifest in group interactions and link to the formation and regulation of emotions. A better understanding of these relations would assist educators in helping students engage in positive interactions and overall collaboration. Therefore, in this study, we examined the role of talk types in small group learning.

Our work is derived from the theory of the Formation and Regulation of Emotions in Collaborative Learning (FRECL; Lobczowski, 2020). Per this model, groups are situated within a given *context* shaped by the individuals within the group, interactions between group members, and engagement with various components of small group learning (e.g., the task). Then, a *stimulus event* occurs, followed by an *appraisal* (i.e., cognitive representation of motivational constructs) and ultimately an *emotion* (e.g., happiness) and *response* (e.g., frowning). Upon completion of the formation stages (i.e., context, stimulus event, appraisal, and emotional response), the students may engage in regulation (i.e., the fifth stage). This theory highlights the complex nature of emotions in group settings but does not explicitly consider the role of social discourse within each of the stages. As such, we used an exploratory approach to analyze talk turns from mostly unstructured group discussions to qualitatively investigate: *(1) the different talk types student groups used in a project-based learning course* and *(2) how the talk types linked to the formation and regulation of emotions.*

Methods

Our participants included six groups of four to five second-year graduate pharmacy school students (n = 29) from the southeastern United States. These students were given a project-based task to create innovative solutions for real-world pharmacy problems. This study is part of a larger project in which we recruited the groups to use an app to rate their emotions during biweekly group meetings. These ratings revealed groups with high, medium, or low levels of positive emotional experiences. We analyzed the conversations from three groups (i.e., one high, medium, and low), which occurred during nine two-hour group meetings, totaling 27 group meetings analyzed.

Part of the larger project included deductively and inductively coding talk turns to develop a scheme to highlight the different types of talk used by the student groups (see Table 1). These codes were influenced by context (e.g., conversations before and after utterances) and observable emotional expressions, as evidenced through body language, facial expressions, and tone (Lobczowski, 2020). Coding from the larger project resulted in over 90% agreement and 100% after reconciliation. To connect the talk types to socioemotional formulation and regulation, we identified themes specifically related to the five stages of the FRECL model.

Table 1: Talk Type Codes

Code	Definition	Examples
Apologizing	Saying sorry for social reasons	"I'm sorry, can you repeat it?"
Calling out	Lightly challenging someone about something they said or did	"That's not what you said before."
Challenging	Engaging in argumentation; debating or negotiating ideas	"I disagree."
Comforting	Providing relief to a group member	"Don't be so hard on yourself!"
Complaining	Discussing tensions, positioning as right or others as wrong	"The professor still hasn't replied."

Complaining about group member	Similar to complaining, but focused on a specific member in the group	"I can't believe Mark is skipping our meeting."
Complimenting	Giving compliments to someone (present) in the group	"I like what you did there."
Confronting	Discussing frustrations about a person in the group	"I can't believe you did that."
Correcting	Pointing out and fixing a mistake from someone else	"Well, actually, that's wrong."
Encouraging	Providing support to someone to engage in task or discussion	"Tim, what did you think?
Gossiping	Discussing personal facts about others (typically not present)	"Did you hear about Dr. Smith?"
Gushing	Excitedly sharing positive emotions (or their causes)	"I had so much fun this weekend."
Hear me out	Calling for others to pay attention to what they are saying	"Listen up, I've got an idea…"
Hedging	Presenting ideas without taking a firm stance	"I'm open to other ideas."
Help-seeking	Asking for help	"Can you explain this to me?"
Interrupting	Beginning to speak while others are still talking	A student cut someone off.
Joking	Making jokes about someone or something not currently present	"Did you see what he is wearing?"
Joking/teasing about conflict	Making jokes or teasing about conflict among group members	"Maybe that is why we always seem to be fighting!"
Self-deprecating humor	Making fun of oneself or pointing out one's own flaws	"You know me, always saying the wrong thing!"
Storytelling	Telling a story to the other members of the group	"That reminds me of a time..."
Teasing	Making jokes about a person in the group	"What are you wearing?"
Tension relaxation	Easing group tension by joking or teasing	"Well, now you've confused Jon!"
Venting	Discussing frustrations that are outside of their control	"My car broke down again today."

Results and discussion

We observed 23 different talk types during the student group meetings (see Table 1). Next, we were able to connect the talk types to the different stages of the FRECL model. Although each talk type could occur in different stages, some were more salient in certain stages. First, student discourse (e.g., joking, confronting, correcting) shaped the groups' daily interactions, social norms, and perceptions of others' emotional experiences, thus setting the overall tone for the group (i.e., *context*). Next, the talk types (e.g., teasing, challenging) served as *stimulus events*, with occasional verbalizations (e.g., self-deprecating humor) of *appraisals* of the meanings and intentions for the social discourse. Based on these appraisals, the students then *responded emotionally* to the talk types through visual displays (e.g., facial expressions) and verbalizations (e.g., complaining, gushing). Finally, some talk types (e.g., venting, comforting) were used as *regulation* strategies.

Our findings, framed within the FRECL model, highlight the integral role that social discourse plays in the formation and regulation of emotions within collaborative learning settings. The observed talk types elaborate on the currently available literature and offer a coding scheme for deeper analysis of socioemotional interactions. Our findings regarding how talk types relate to the formation and regulation of emotion have implications for future research and practice. For example, educators can monitor student discourse for maladaptive talk types and intervene when needed. Likewise, researchers can develop interventions to promote productive talk types during collaborative learning.

Integrating Data Science Explorations in Science Classrooms

Bodong Chen, Rukmini Avadhanam
henbd@umn.edu, avadh005@umn.edu
University of Minnesota

Abstract: We propose a technology-enriched learning intervention named DataX to engage students in analyzing authentic datasets about societal issues. In a pilot conducted in secondary science, students were first introduced to basic data concepts and then invited to analyze multivariate data about energy and chemical elements. Some students demonstrated sophisticated data skills and playfulness despite initial negative dispositions to data. This study showed early promise of DataX for engaging students in authentic data explorations.

Introduction

Data has been recognized as an important fabric of modern society. It is therefore crucial to seek means to cultivate data-literate citizens so that they are equipped with knowledge, skills, and dispositions important for disciplinary and civic engagement.

Data science as an emerging discipline has garnered significant attention across levels of education (Rosenberg & Chen, 2020; Wilkerson & Polman, 2020). In K-12, a key approach to supporting data science is to interleave it within existing subject areas including statistics, science, engineering, and social sciences. This paper reports on an ongoing design-based research project aiming to develop a technology-enriched learning intervention named *DataX* that positions students as "data analysts" who can build knowledge about important societal issues by collaboratively analyzing authentic datasets in specific disciplinary contexts. In the following sections, we describe the DataX project and report key findings from a pilot study.

The DataX project

We conceptualize student experiences with data as an integral part of their disciplinary and civic engagement. To support this conception, DataX situates data in a larger inquiry process of value to students, aiming to develop "students' identities as agentive data practitioners" who recognize the roles of data in various social contexts and are both capable and willing to use data skills to drive social change (Wilkerson & Polman, 2020, p. 4).

The DataX online environment builds on CODAP (Common Online Data Analysis Platform), an open-source tool designed for Grades 6-14 students to view, transform, analyze, visualize, and interpret data. DataX extends CODAP from an individual-oriented tool to a community-centric, knowledge-building environment that allows learners to collaborate on data investigations. In particular, DataX allows learners to publish data analysis notebooks for others to comment on or remix.

With the designed technology, we conducted a pilot study to examine how students may use support provided by the DataX intervention. We asked: (a) What data experiences and dispositions did students bring into this intervention? (b) To what extent did DataX facilitate students' data explorations and data dispositions?

Methods

This study involved two public schools in a metropolitan area in the midwestern United States. Participants were two science teachers and 81 students from their 11th grade classes.

Before the classroom intervention, we worked closely with the teachers to co-design pedagogical supports responsive to their classes. Through multiple design meetings, we created an overarching plan for their classes to work on the NGSS crosscutting concept of "energy" from different angels.

During the pilot, a pre-survey on students' prior data experiences and data dispositions was first administered in both classes. After the pre-survey, the researchers conducted a mini lesson on several basic ideas about data, discussing "what is data" and exploring real-world examples about data. In the same session, students were introduced to the DataX environment, followed by a warm-up data activity on visualizing a public dataset. After the introductory session, two classes diverged: Class A did a data investigation on energy consumption in the US, whereas Class B investigated the properties of elements in the periodic table. Researchers and teachers provided continuous scaffolding in both classes. Although more DataX sessions were planned, COVID-19 and the emergency transition to remote learning disrupted the pilot, before we could engage students in further investigations.

Multiple sources of data were collected, including the pre-survey, student-generated data artifacts in DataX, videos of classroom activities, researcher field notes, and teacher interviews. To answer research questions, we first analyzed student responses to the pre-survey and identified different data dispositions profiles. Using the profiles, we sampled several students and examined their data artifacts on DataX. Researchers' field notes, video recordings, and teacher interviews were incorporated as secondary data.

Results

Overall, students brought a wide range of data dispositions into the study. Descriptive analysis of the pre-survey showed that nearly 80% of the students found data to be interesting or very interesting; about 78% of students indicated that they like or love data-related activities. Students were approximately normally distributed in their interest in reading graphs, thinking about data, seeking data behind news stories, and exploring complex problems. In terms of experiences with data, about 45% of students indicated they were comfortable working with large amount of data, while the remaining 52% said no.

Starting from students' pre-survey responses, we purposefully sampled four students based on their data dispositions and inspected their DataX notebooks. Overall, we found some students with little data experiences or less positive dispositions ended up doing quite well in their data explorations. For example, Student 1 entered the pilot with an interest in data and data activities. This student' DataX artifacts showed the student was able to read the data and create a simple visualization on the natural state and boiling point of elements in the periodic table, but could not "read beyond the data" to interpret what the graph means. In contrast, Student 2 did not like doing data activities but was able to read "between" and "beyond" the data during the intervention. This student visualized the natural states and boiling points of different elements and was able to interpret that boiling solids would take longer than liquids or gases (see Fig. 1, left). In other cases, students demonstrated a willingness to play or tinker with data. Student 3 from Class B independently created a line graph (see Fig. 1, right) using the energy dataset. Even though the student did not come up with a solid interpretation, this representation is peculiarly novel, and he was looking closely at the graph to make sense of the multivariate relationships.

Teacher interviews indicated that the pilot gave students new opportunities to work on and manipulate data and helped students think more about data in science contexts. One teacher said: "DataX allowed students to connect actual scientific information about the concepts we were studying around energy [and] energy usage and apply that to [we] know not only [about] the world now [but also] the world before." Teachers also highlighted that the activities offered authentic learning experiences for students to connect learning to real life situations. Some students expressed an interest in analyzing energy consumption of countries their families immigrated from.

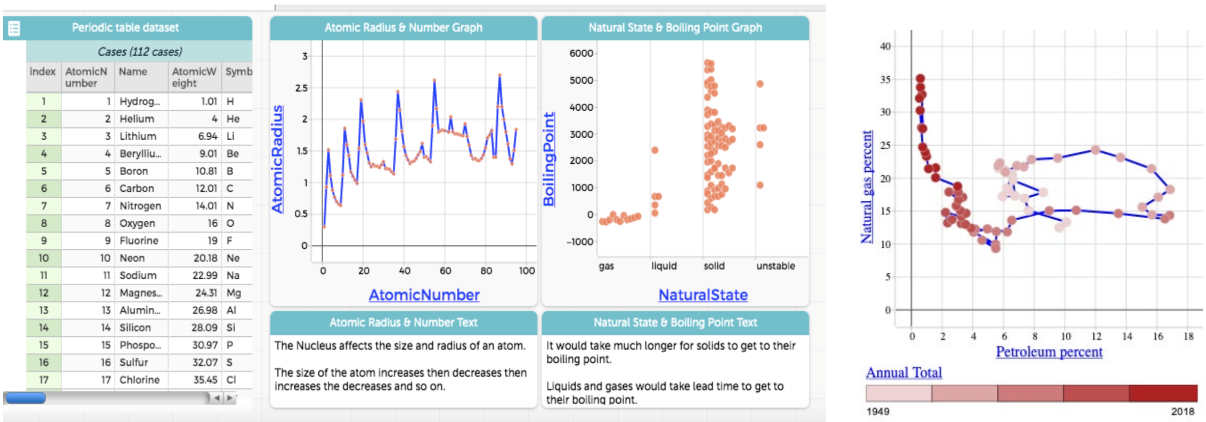

Figure 1. Screenshots of the DataX notebooks created by Student 2 (*left*) and Student 3 (*right*).

Conclusions

The DataX intervention showed early promise for engaging students in authentic data explorations relevant to important disciplinary contexts and societal issues. Future work will continue to revise the technological and pedagogical designs of DataX to facilitate student learning in data science.

Merging Teacher Professional Development with Designing Curriculum Incorporating Cutting-Edge Science in a Natural History Museum

Heather Killen, Smithsonian Institution National Museum of Natural History, hkillen@umd.edu
Laura Soul, Natural History Museum , London, laura.soul@nhm.ac.uk
Rich Barclay, Smithsonian Institution National Museum of Natural History, BarclayRS@si.edu

Abstract: We brought together high school science teachers, paleoclimate scientists, and museum educators/researchers as a museum-based scientist/teacher inquiry group (or mSTIG) to merge a one-day teacher professional development opportunity at the Smithsonian's National Museum of Natural History with curriculum design ideation to create formal lessons utilizing cutting-edge climate change science. Here we report the first of three benefits. We suggest our mSTIG model can be a powerful way to integrate leading scientific thought into formal curriculum and that natural history museums are compelling places for this type of synergy.

Introduction

It can be difficult for the leading edge of scientific thought to make its way into formal primary or secondary education, in large part because curriculum designers and world-class scientists are rarely in the same spaces. In order to investigate how the unique space of a natural history museum might be leveraged to support scientist, teacher, curriculum designer collaboration we sought to answer the following research question: *What are the affordances when combining teacher professional development and curriculum design using design-based research methodologies in a museum context?* To answer this question our team brought together a museum-based scientist/teacher inquiry group, or mSTIG, composed of teachers, scientists, museum educators, and curriculum designers. This mSTIG developed proto-lesson ideas, termed lesson seeds, which the research team then analyzed for insight on how best to build formal high school curriculum highlighting the science of the Fossil Atmospheres project (Barclay and Wing, 2016; Soul et al., 2019). The Fossil Atmospheres project uses Ginkgo leaf fossils, along with historic herbarium leaf samples and modern leaves collected in nature and grown under experimental CO_2 conditions, to explain ancient and future climate change.

In designing this PD, we were mindful of best practices highlighted by literature involving teacher PD in science (Darling-Hammond et al., 2017) while encouraging, through the mSTIG design, active learning. As curricular designers, the research team approached the mSTIG participants with a Funds of Knowledge mindset (González et al., 2006) and used aspects of design-based research (DBR) methodology. Finally, we grounded our collaborative learning and community building in the Community of Practice tradition (Lave and Wegner, 1991), structuring our PD around the shared goals of understanding complicated scientific knowledge and then designing instructional activities that integrated that knowledge. Specifically, we adapted the STIG inquiry group model Killen et al. (2019) used previously for PD involving integration of computational thinking into lesson design.

Design and data collection

The mSTIG included 14 teachers and took place during 8 hours on a Saturday within an education space at the National Museum of Natural History (NMNH) in Washington DC, USA. The mSTIG was composed of four activities: group brainstorming; a discussion of teacher resources available when teaching climate change; a presentation of the science of the Fossil Atmospheres project, and teachers, in grade-level groupings, thinking specifically about how they might build a lesson using the science of the Fossil Atmospheres project. The lead author qualitatively analyzed teacher surveys, mSTIG artifacts and the notes and recollections of museum personnel. Transcripts of the video underwent two cycles of coding: inductive and axial (Saldaña, 2015).

Findings

Three broad affordances were found: teachers learned from scientists the newest understandings of climate change, scientists were challenged to clearly present their work to teachers, and museum educators/researchers learned from teachers how to best incorporate cutting-edge science into useful, engaging curriculum. We found the mSTIG DBR design was a key difference between mSTIG teacher PD and the more traditional museum-based past teacher PD experiences NMNH had offered and allowed for an important benefit; teachers were able to surface any gaps in their understanding which were then immediately addressed by either fellow teachers or scientists while they were actively involved in the real and meaningful exercise of integrating particular science concepts and practices into science lessons they would find useful and that they thought their students would find engaging. This is seen in following exchange between two teachers.

Celeste: She [one of the project scientists] mentioned that all the textbooks are going to call this the Anthropocene.

Shasta: Well, yeah, that's definitely still something that is still under debate, but yeah.

Celeste: Well, no, they decided to do it, the question is when.

Shasta: Which group is deciding to do it? It's kind of like the Planetary Society says Pluto's a planet, Astronomical Society says it's not. So, what's . . . Which group are you-

Celeste: I don't think the Planetary Society says . . . But that's neither here nor there. My point was only that, is it at the age of harnessing the ability to make fire? Because that changed the environment. They're arguing that . . . should it be with the beginning of the cultural revolution? Should it be with the hunting of the megafauna? Should it be with the first industrial revolution, the second? Should it be the atomic revolution?

Shasta: Yeah, well, some things to more extent than others. Certainly. Gatherers caused huge changes to the environment.

Celeste: Right, right. So, do you want to make that the focal point?

Here, working together to build a lesson seed created an opportunity for Celeste and Shasta to have an interaction that would have been less likely within a more passive teacher PD model. Shasta expressed her hesitancy about the validity of the Anthropocene. Celeste was able to respond with an accurate review of current scientific thinking and then bring the conversation back to the mechanics of their lesson seed without causing tension.

Discussion and conclusion

This work leveraged the multidisciplinary space of a natural history museum to bring scientists working at the leading edge of their field together with U.S. high school teachers, museum educators and curriculum designers/researchers to form a mSTIG community that accrued benefit to every participant group. By combining PD with a DBR opportunity, teachers were able to immediately apply new scientific knowledge to a context they were expert in - teaching science to their students, thereby surfacing gaps in knowledge that could immediately be addressed.

Responding to STEM Students' Gestured Candidate Responses

Virginia J. Flood, Graduate School of Education, University at Buffalo, SUNY, vflood@buffalo.edu
Benedikt W. Harrer, Department of Physics, University at Buffalo, SUNY, bwharrer@buffalo.edu

Abstract: We demonstrate a way in which teachers can be responsive to students' multimodal contributions in whole-class STEM discussions. To answer teachers' questions, students sometimes use representational gestures to provide unspoken, "off-the-record," tentative responses. By attending to these *gestured candidate responses,* teachers can preview students' potential contributions to the discussion and ratify the contribution. Ratified contributions can be taken up by the teacher and shared with the class. This study contributes to a better understanding of the nuanced roles gesture plays in STEM classroom discourse.

Gesture and responsive teaching in STEM learning

In STEM classrooms, whole-class discussions provide important opportunities for students to co-construct new knowledge (O'Connor & Michaels, 1996). During these discussions, the body is an essential resource for meaning-making: STEM teachers and students regularly use gesture to share and negotiate new understandings together (e.g., Singer, 2017). In particular, students use gesture to make sense of abstract concepts and explain STEM ideas before they have mastered the complex languages of STEM disciplines (e.g., Roth & Lawless, 2002).

STEM educators can take up and be responsive (Coffey et al., 2011) to students' gestures in a variety of ways. These include (1) encouraging students to elaborate their gestures when there are discrepancies between gesture and speech (e.g., Flood et al., 2020), (2) repeating students' gestures to help students connect embodied ideas with rephrased speech (e.g., Alibali et al., 2019; Shein, 2012), and (3) reformulating and extending students' gestures to refine and elaborate the spatio-dynamic imagery available to students (Flood, 2021). A number of embodied responsive teaching techniques have been identified (Flood, et al., 2020; Flood, 2021). By eliciting, attending to, and responding to the ideas students share with their hands and bodies, educators help students make new STEM discoveries, thus enriching opportunities for learning (Flood et al., 2020; Flood, 2021).

Our current study extends previous work on the role of teachers' responsiveness to gestures in whole-classroom discussion (Flood, 2021). We demonstrate how students in physical science class use gestures to make "off-the-record," tentative contributions – *gestured candidate responses* – to answer teachers' questions. By attending to these gestured candidate responses, teachers can take stock of what students could contribute to the ongoing discussion, and then decide to pursue and endorse the contribution, for example by taking up and repeating the gesture publicly. Teachers can also invite students to elaborate on the idea, themselves.

Methodological approach

We draw on a video corpus of two-week long energy units in two eighth-grade science classrooms in the Northeastern U.S. The classrooms feature project-based learning and contain numerous interactive whole-class discussions where students share ideas. We located instances where students used representational gestures to respond to teacher queries. Then, inspired by ethnomethodological conversation analysis, we microanalyzed the embodied communicational practices of teachers and students in these instances to understand how and when gestures were deployed and coordinated with other interactional resources (e.g., gaze, talk).

Findings: Teachers take up gestured candidate responses

We present a representative example from our study to demonstrate how teachers can take up students' gestured candidate responses in classroom discussions. In Excerpt 1, the class is discussing energy and friction (1). Energy cannot be directly perceived and must be studied through the use of indicators that can be measured, like light, heat, and motion. To discuss this problem with students, the teacher reminds the class of another use of indicators they have seen: She asks the class to recall friction indicators, and students offer sound (hearing a door creak) and seeing a model car veer as examples. She asks them to think of more, but no one volunteers. After a pause (E1.02), the teacher asks the class to remember how they explored friction through demonstrations (E1.03-04).

Dan responds, speaking inaudibly (E1.05). It is unclear if the teacher can hear what he says, and students across the room would not be able to make out his words. Dan's response is multimodal, and he looks toward the teacher as he talks and gestures, rubbing his hands together (Figure 1a). Rubbing your hands is a good way to *feel* the presence of friction, since the rubbing generates heat and resistance, both indicators of friction. At this moment, the teacher's head was turned slightly away from Dan, and she was scanning the room. However, she seems to catch Dan's gesture from the corner of her eye. As soon as Dan starts rubbing his hands, she turns her head toward him. By not officially bidding to answer with a raised hand, speaking so as not to be heard by the rest of the class, and gesturing, Dan marks his response as a *candidate* for the teacher to acknowledge or ignore.

Excerpt 1. Friction

```
01 T: Measure see hear is that pretty much–
02    (1.6)
03    Can we thi::nk of how we tried to
04    understand friction in demonstrations↑
05 D: °Like how it feels° ((barely audible,
06    likely inaudible for most of class))
07 T: Feel.
08    (1.7)
09    We did this all:: the time.
```

Figure 1. Taking up a *gestured candidate response* of hand rubbing. Blue highlighted talk corresponds to image (a) and green highlighted talk to image (b). In (c) and (d) other students copy the hand rubbing.

As Dan continues to rub his hands together, the teacher also holds her hands up in view of the whole class and begins to rub them together (Figure 1b), ratifying Dan's response. As she takes up and repeats Dan's gesture, she says loudly out to the class "Feel" (E1.07). She continues to rub her hands together and look around the room. Many students also start rubbing their hands: Of the 15 students in the room, seven repeat the gesture, and the teacher continues to rub her hands together for 16 seconds as other students take up the gesture.

By attending to Dan's gesture, taking it up, and repeating it for the whole class, the teacher shares Dan's embodied knowledge with everyone. Most students would not be able to hear Dan, and in addition, many also likely did not see Dan's hands because of where they were seated. By repeating the hand-rubbing, the teacher provides implicit feedback about Dan's response, endorsing the gesture as a valuable embodied way of knowing about friction. When other students repeat the gesture, they have an opportunity to also experience *feeling* indicators of friction (e.g., heat, roughness). O'Connor and Michaels (1996) argue that one of a teacher's key jobs in orchestrating classroom discussions is to "hold students' ideas in view." By attending to Dan's gestured candidate understanding and repeating it for all to see and feel, the teacher in Excerpt 1 literally does just that.

Conclusion

By attending to *gestured candidate responses,* teachers can take up and broadcast students' tentative ideas to the class. Our study contributes to a growing body of work that demonstrates how responsive teaching is an embodied, multimodal phenomenon, where teachers attend and respond to disciplinary substance (Coffey et al., 2011) not just in what students say, but also in the meanings students convey with their hands and bodies (Alibali et al., 2019; Flood, 2021; Shein, 2012). Our efforts to investigate the ways instructors attend and respond to gestures during whole-class STEM discussions contribute to more systematically characterizing the many forms and functions of embodied communication in STEM learning. Our future work will continue to explore and characterize the different roles gesture can play in organizing whole-class STEM discussions.

Abstract: School-based science inquiry tends to focus on already answered questions. We describe how we used the COVID-19 pandemic in a high school citizen science unit for students to witness and engage in real-time science. High school students developed proposals to study questions about their experiences related to the pandemic. Teacher and student interviews and observations showed that this globally-relevant experience also offered a personally relevant context through which to understand the scientific process.

Introduction and conceptual framework

COVID-19 has brought science to the forefront of public discussion, and highlighted the importance of scientific collaboration and transparency at all levels of its process (Fry, Cai, Zhang & Wagner, 2020; Rempel, 2020). While this global event had serious implications for students' lives (illness, social isolation, shift to online schooling, inaccessibility of public spaces), it also created opportunities for authentic inquiry learning experiences. Whereas traditional science inquiry learning in US schools tends to focus on already answered inquiry questions (Furtak & Penuel, 2019; Linn, Gerard & Matuk, 2016), we saw an opportunity for citizen science (CS) to leverage the global relevance of the pandemic for students to witness and engage in the scientific process unfolding in real-time, and particularly around questions that were personally relevant to their experiences at the time. In classroom-based CS, students and teachers contribute to the work of scientists by generating research questions and participating in data collection and analyses (NRC, 2012). In this study, we ask: How can real-time phenomena, like a pandemic, support students in learning about the scientific inquiry process? We report on initial findings from our implementation of a CS unit on human behavior related to the pandemic.

This work is grounded in participatory science learning, an approach that emphasizes authentic problems, the social negotiation of knowledge, the roles of more knowledgeable others, reflection, and students becoming members of a community (Barab & Hay, 2001). Our design embodies the ideals of participatory science learning by supporting students' collaboration with peers and experts, encouraging them to identify and pursue personally and socially relevant questions, and guiding them through an authentic process of iterative inquiry and reflection. It is through this lens that we both designed the unit, and conducted our analyses.

Methods: Context, participants, and data

We collaborated with a science teacher at a private high school, Ms. C, to implement a 4-week long unit on brain and behavior (B&B) research in her class of 20 juniors and seniors (18 of whom participated in this study). The initial curriculum design focused on the relationship between environmental decision-making and human behavior (e.g. what leads to pro-environmental behavior, psychology of climate change). The unit's learning goals included introducing students to open science, ethics in human subjects research, B&B experimental study design, research proposal writing, and scientific peer review. Students' proposal development also leveraged a beta version of MindHive, a web-based CS platform, that facilitates the proposal, data collection, and analyses of research projects. During the unit, the beta MindHive platform hosted two B&B citizen science research studies (i.e. social influence and climate change, risk-taking in adolescents) designed by partner scientists. Students, via MindHive, participated in these studies and the unit also leveraged the studies as cases to teach experimental design, proposal writing, and introduce basic analysis. When the pandemic shuttered schools and forced us to move online just 2 weeks before implementation, our team opted to use COVID-19 as a relevant context for the aforementioned learning goals. This involved curriculum changes like integrating a lesson on the role of preprints and peer review that utilized active research about COVID-19. We also pivoted to supporting students in developing inquiry questions about the pandemic and recast existing content (e.g., experimental design) in terms of studying pandemic-related behaviors (e.g., social isolation, disrupted routines, mask wearing, online learning). Our data include an interview with Ms. C and an interview with 2 students, asking them to reflect on their experiences implementing and participating in the unit respectively. We also collected draft and final research proposals from all four groups, field notes from synchronous class sessions, post-unit student reflections from 10 of the 17 students, and curriculum materials. Our preliminary analyses used open coding (Charmaz, 2014) to explore the impacts of contextualizing students' CS inquiry within an unfolding pandemic on students' attitudes toward, and understanding of the nature of the scientific process.

Findings

Our initial analyses show 1) how students' proposals gave them opportunities to pursue personally and socially relevant questions 2) how participating in a proposal writing process led to insights about scientific inquiry 3) how students' attitudes toward the scientific research process changed throughout the unit. Students' research questions were at once based in their personal experiences, as well as novel and globally relevant (e.g., "How is zoom school affecting student mental health and morale?"). In addition, students gleaned insight about authentic science as revealed in their culminating reflections like, "the interdisciplinary and cooperative nature of science… was something that I had not thought much about prior to this semester in science." Students also started to understand key facets of scientific inquiry like the iterative nature of scientific discovery and its relationship to experimental design in B&B: "I never really understood just how much research was required before going into an experiment. I always assumed that it was simply looking into something you want to test, but there's a lot of preparation involved for each experiment." Ms. C also underscored the value of a participatory science (Barab & Hay, 2001) explaining, "there is something about going through a process from beginning to end… when we're writing a lab report (in class), we'll often skip procedures. This experience was really thorough… This project brought new members into the class community; professionals with academic credentials; collaborating on a different level who wanted to know what students had to say and what they were thinking." Being in conversation with scientists and exploring authentic phenomena made the curriculum experience compelling and valuable. However, students found it difficult to effectively collaborate remotely, resulting in discordance over research questions, collecting background research, and designing tasks. Ms. C also noted that ideally synchronous class sessions would have been more student-centered, but online learning instead emphasized adult-led lessons.

Significance

This study shows the value of using an unfolding global event as a context for students to learn about the scientific process. It also demonstrates how CS learning can continue amid disruptions caused by the pandemic: By leveraging its global and personal contexts, we can engage students in investigating personally and socially relevant questions that also contribute to emerging knowledge about crises through open and participatory science.

No Player Left Behind: Exploring the Use of Collaborative Talk in a Playfixing Activity

Yuchan (Blanche) Gao, Jeremy Bernier, Taylor M. Kessner, Luis E. Pérez Cortés, Elisabeth R. Gee
ygao148@asu.edu, jeremy.bernier@asu.edu, tkessner@asu.edu, leperezc@asu.edu, elisabeth.gee@asu.edu
Arizona State University

Abstract: This study describes an activity in which participants play and fix broken games through the use of collaborative talk (CT). The playfixing activity provides a useful context for examining how participants collectively redesign an incomplete tabletop game. We qualitatively analyzed participants' talk as they playfixed a game, *Pollutaplop*. This study contributes to the design of future learning experiences that invite the use of CT and foster the development of abilities to collaborate on complex tasks.

Introduction

The ability to collaborate within small groups to solve collective problems is crucial for life and work in the 21st century. School-related learning experiences frequently are organized around well-defined tasks or problems, in the sense that learners—often individually—work towards finding one predetermined solution to a problem. While such problem structures offer affordances for learning, they often lack the authenticity of the wicked problems defining the modern world, problems for which definitive answers remain elusive but nonetheless require collaborative approaches to tackle (Kessner et al. 2020). As such, a crucial question becomes apparent: how might activities that foster such collaborative abilities look? In this poster, we describe how an activity in which participants simultaneously play and fix (playfix) "broken" games may offer a useful example to inspire the design and organization of future learning experiences that foster young people's abilities to collaborate on complex tasks that approximate the kinds of wicked problems they will confront in the real world.

This study draws on three notions: collaboration as a learning goal, design as a context, and talk as a meaning-making tool. Collaboration as both a goal and a method for learning has been popular for decades, and there is a robust literature on how to support collaboration in and out of educational settings with participants of all ages (Smith & Mancy, 2018). However, successful collaboration remains a somewhat elusive goal in many contexts, and there is no formula or definitive set of "skills" required for successful collaboration. At minimum, the nature and goals of the task or learning activity must be specified in order to identify the most salient forms of interaction that participants must engage in. The growing interest in design and design-based learning represent important contexts for understanding and cultivating successful collaboration and learning. Design efforts are typically aimed at addressing ill-structured or even wicked problems and thus may depend on forms of collaboration that might differ from, or have different importance than, those required for collaboration around the more well-structured problems typical of many school assignments. From this perspective, collaboration can be viewed and analyzed as a process that gradually leads two or more people to construct shared meanings for conversations, concepts, and experiences (Roschelle, 1992). Talk, from a sociocultural view, remains a central means of building shared understandings, and scholars have proposed various ways to characterize what Newman (2016) and others have called *collaborative talk*—a strategy that participants adopt to jointly work toward the shared goals.

Learning scientists emphasize the importance of understanding learning in context. In the context of our task-participant structure, participants were required to simultaneously play and fix (playfix) broken games—tabletop games intentionally left unfinished, with ambiguous rules and mechanics. That is, they (a) played the broken game in order to fix it, and (b) fixed the broken game in order to play it. In summary, the playfixing activity invites participants to collaborate on solving an ill-structured problem of the broken game. In this study, we ask: *To what extent does playfixing a broken game facilitate the use of collaborative talk among participants?*

Data collection and analysis

The data used in this study were collected as part of a larger investigation of the processes and outcomes of playfixing broken games. This study focused on one 45-minute session in which four adult participants were given a broken game *Pollutaplop*—a tabletop game in which players eliminate waste from biomes of an interconnected water-based ecosystem (see Figure 1)—and asked to identify and "fix" any issues in the game while they play through it. Influenced by previous scholarship on peer dialogue and dialogic talk, Newman (2016) conceptualized CT as a process of *participating* (speakers' active contribution to CT), *understanding* (speakers' attempts to interpret and respond to the contribution of others), and *managing* (speakers adopt their position and monitor their participation). To better understand the enactment of CT in our playfixing case, we retained Newman's (2016) broad categories but modified the definitions and descriptors to more explicitly align with the playfixing activity. Overall, our aim was to create descriptors of talk that could be identified in a transcribed discussion.

Figure 1. Pollutaplop.

Findings and discussion

Here we describe two salient findings. Firstly, the two design episodes consisted of a total of 176 utterances (see Figure 2). Of these, 120 utterances were coded as some form of CT while 56 utterances were uncoded as they were either unfinished utterances or did not contribute to CT. Thus, the majority (68%) of participants' talk during the design episodes consisted of some aspect of CT. Secondly, we found that the strands of CT (i.e., participating, understanding, managing) in the playfixing activity appeared to be interdependent, reflected in how the three elements of CT overlapped and intertwined. The way players participated in CT was influenced by how they understood and managed the talk. Understanding assumed active participation and set the foundation for effective managing—constructing new meanings (e.g., modified game rules). Rather than a unidirectional or step-by-step process of building shared understandings, participants simultaneously offered and clarified suggestions, elaborated different ideas, and interjected to steer the direction of their talk as needed. We also found that some of the players' utterances represented multiple CT strands, revealing participants utilized different CT strands to complete the playfixing activity.

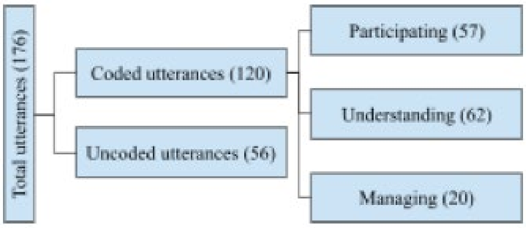

Figure 2. Coded and uncoded utterances.

Conclusion

In this 45-minute playfixing experience, we found considerable evidence of CT, and our analyses also suggest how CT—and collective meaning-making—was interwoven with game play. The common activity of playfixing a board game offered opportunities for shared meaning-making that included even otherwise indifferent participants. We argue that, although broken games are incomplete, they offer participants an engaging opportunity to think about the game that they are fixing and the content they are discussing.

Thinking through Representation: Interpreting Representational Fluency across Contexts in Computational Thinking Enhanced Activities

Janet Bih Fofang, David Weintrop, Peter Moon, Andrew Elby
bihjane@umd.edu, weintrop@umd.edu, pmoon@umd.edu, elby@umd.edu
University of Maryland

Abstract: In this study, we investigated the emergence of representational fluency in fourth-grade students as they engaged in a robot-mediated task designed to integrate computational thinking (CT) and mathematics. We observed two pairs of students who were engaged in programming a Sphero robot to navigate a maze during a mathematics lesson. We found that the students used language and embodied gestures as forms of representational fluency to mediate the mathematics and CT present in the activity.

Introduction

Representational fluency is crucial to STEM education because learners rely on multiple representations to translate across concepts in problem solving environments. Representations can serve as useful tools to support young learners scaffold abstract concepts as they navigate virtual and physical environments (Brown, Collins, & Duguid, 1989). Technology enhanced computational thinking (CT) environments typically involve software and user interfaces that can empower users to be more innovative in their problem-solving strategies (Resnick et al., 2005).

In this study, we investigate different forms of representational fluency students engaged in as a strategy to program a Sphero robot to navigate a prime number maze (figure 1). Furthermore, we inquired about specific symbolic features, arrangements and relationships within and across the learning environment and how the design of the environment gave room for multiple forms of representations to emerge.

Figure 1. The prime number activity board (a) the Sphero robot (b)

Theoretical orientation and methodological approach

We review research on representational fluency, and other theoretical perspectives that draw on a situative approach to learning (Brown, Collins, & Duguid, 1989). The situative approach foregrounds learning and understanding in terms of the inquiry of interactions made between people and the material, symbolic and technological resources of the environment. This theory, alongside frameworks on representational fluency (Alibali & Nathan, 2012; Korzma 2003) guides our understanding of how young learners navigate representations in a CT enhanced learning environment. Our study investigates how younger learners can engage in different modalities of representations such as speech, gesture and writing to support their cognitive strategies in a Sphero robot and prime number maze problem solving activity.

Two pairs of students were selected from one of the public schools involved in a District of Columbia Public Schools (DCPS) Research Practice Partnership (RPP), focused on integrating CT in elementary math classrooms. Three cameras per group were used to capture the students' actions. In addition, both students in each group wore head-mounted cameras. We use a case study approach in order to provide detailed understanding of how students engage with Sphero robots to problem solve in a math classroom. For example; program the Sphero robot to navigate a prime number maze. We watched the clips as a team and discussed our observations to come to a consensus whether our claims had enough evidence from the videos. We clipped video instances where students engaged in representational fluency practices, and transcribed for analysis. The transcript was analyzed for representational fluency evidence through a holistic coding process where two team members memoed observations on an excel spreadsheet, highlighting evidence of representational fluency.

Findings

Analysis identified instances during which the participants either engaged in representations through gesturing, used metaphors or described their programming strategies to ground their understanding of concepts or as ways to actively *build cohesion* across representations. We noticed that the students had to align all the cues provided by the environment, each with a different representation, in order to make the robot navigate the maze. Such translations between concrete and abstract concepts, and virtual and physical interactions, required fluency across these representations in which each context could be equal in meaning but represented differently. In some instances, students used speech and gesture representations to map out the prime number maze. Deictic (pointing) gestures were heavily used to distinguish what counted as prime numbers and figuratively tracing out the maze at the same time.

Computational thinking enhanced environments can be generative environments for students to develop representational fluency in order to navigate complex multimodal physical and virtual environments. The current study observed representational fluency can be a useful strategy for problem solving. It is possible that our data could highlight more representations within the virtual programming space if we had access to the programs the students wrote on their iPad using the Sphero application. Although the current study is part of a larger project involving the introduction of CT in fourth grade classrooms, we aspire to demonstrate sufficient evidence about the physical, virtual and embodied representations. Such evidence aligns with the situative approach to learning and understanding in terms of the inquiry of interactions made between people and the material, symbolic and technological resources of the environment as posited by (Brown, Collins, & Duguid, 1989). We therefore consider these strategies to be useful for educators and curriculum designers who wish to integrate CT activities into their lessons, to think about the scaffolds that will allow for representational fluency to emerge and support translations across concepts, representations, and even disciplines (Nathan et al., 2017).

“Do I hear buzzing?” Emergent Bilinguals Engaging in Science

Sarah J. Lee, Vanderbilt University, sarah.lee@vanderbilt.edu

Abstract: This study investigated emergent bilinguals’ engagement in a technology enhanced, embodied modeling curriculum about bees. By combining Rodriguez’s (2015) and Engle & Conant’s (2002) definitions of engagement, this paper analyzed moments when students exercised agency in nontraditional ways, shared authority to revise their collective strategies, and formed novel accountability structures as a result of directing their own activities.

Significance and research approach

Emergent bilinguals (EBs) are often excluded from science due to assumptions that English language proficiency must precede content knowledge (Lee & Stephens, 2020). To combat these deficit views of EBs, the current study takes Rodriguez’s (2015) equity-minded definition of engagement and synthesizes it with research on Productive Disciplinary Engagement (PDE; Engle & Conant, 2002) to study elementary EBs’ interactions within an immersive, mixed reality (MR) technology enhanced science curriculum about bees. This study contributes a novel application of existing engagement frameworks to an innovative science learning environment, with a population of students that are often marginalized in traditional classrooms.

This study’s theoretical framework draws on Rodriguez (2015), who provided many examples of practices for promoting engagement that foregrounded student *agency*. For example, “students are provided with some choices for conducting activities and/or projects; Students have choices for representing knowledge” (Rodriguez, 2015). This definition helped us identify student’s agency being exercised in diverse, non-traditional ways. I also draw on Engle and Conant’s (2002) PDE framework, which was developed with monolingual students, for this study to expand researchers’ understanding of engagement to include multilingual learners. The framework provided two components, *authority* (learners share what they really think) and *accountability* (learners explain how their ideas make sense), which require learners to work together, making both concepts particularly useful lenses for studying the current study’s collaborative learning context. With these asset-based lenses—agency, authority, and accountability—in mind, I investigated the research question: What aspects of the learning environment helped support students’ engagement?

The data from this study comes from the larger Science through Technology Enhanced Play (STEP) project, which investigated how elementary school students’ socio-dramatic play can be enhanced by MR software to help them understand complex scientific phenomena. Given my own background from an immigrant, bilingual household, I was drawn to the focal class of this study: a mixed-grades (1st and 2nd), dual language classroom with Spanish-speaking students whose English was limited, as well as English-speaking students who wanted to learn a second language. Although not every child in this class was classified as EB, I analyze interactions of all the children in this study to make claims about how EBs’ engagement in this context differ from traditional science classrooms. The data collection process involved video and audio recordings of eight days of the technology enhanced curriculum about bees and pollination. This study used interaction analysis (Jordan & Henderson, 1995) to select and analyze video data that, based on Rodriguez’s (2015) and Engle’s (2011) definitions, showed students exercising agency, authority, and accountability to engage in scientific learning.

Major findings

This section reports on how the concepts of agency, authority, and accountability helped us investigate how EBs’ engage in scientific practices in diverse and creative ways. Students drove the activities for Day 2 by choosing which strategies of bee foraging to test. Maria (pink shirt in Figure 1), asked the teacher to go into the MR space by herself and have the student-bees follow; this contribution demonstrated Maria’s agency as a learner in this environment. Students also exercised agency over their mode of participation—not only verbal communication and gestures, but also an invented “bee” language—in this environment. On Day 2, Kayley expressed her agency and engagement with the scientific phenomenon in this playful way. Then on Days 3 and 4, other students joined in and a researcher asked, “Do I hear buzzing?” to acknowledge students’ creative form of participation. Maria and Zara on Day 2, and Zara and Hector on Day 4 shared authority over their ideas (collecting strategies and “bee language”) so that their collective understanding of scientific phenomena and communicative tools could deepen to a point they may not have been able to reach individually. On Days 2 and 4, we saw that playful accountability norms allowed for students to persevere despite failures (Dylan celebrating “we almost got full”) to the point that they developed new rules for their invented language system (Hector and Zara sharing what they added to bee language to help them collect nectar more efficiently).

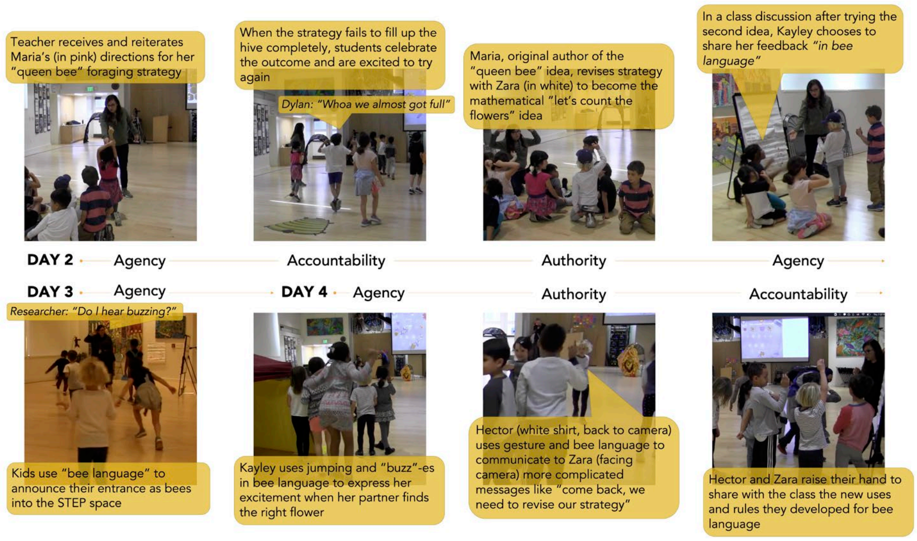

Figure 1. Overview of Days 2-4 with examples of agency, authority, and accountability

Across these three days, we saw examples of how agency, authority, and accountability deepened student engagement. Children led the development of strategies, and invented an imaginary language when they felt English was not sufficient for expressing their (or a bee's) understanding of foraging flowers. This learning environment also valued collaboration and sharing authority, which centered as many student voices as possible, thereby minimizing the chances of marginalizing emergent bilinguals. Because this learning environment normalized "mistakes" and encouraged students to revise their ideas in as many different and creative ways as they want, accountability was redefined as something fun and iterative. Children loved testing new ideas so much that they often ran out of class time to try all their strategies.

Conclusions and implications

The findings showed that this learning environment supported EB students to engage in both traditional and nontraditional ways. The teacher allowed children to direct the activities and to exercise *agency* over how to participate. Contrary to individualistic views on *authority*, the collaborative environment encouraged students to share ownership of ideas with the classroom community in order to co-create and revise their scientific theories. Finally, *accountability* and presenting ideas to one another was framed as something playful and iterative, rather than an arbitrary standard to meet. These opportunities were especially beneficial to EBs who often feel invisible, silenced, or marginalized in science settings. Future research should show how other learning environments can allow for these creative agency, authority, and accountability practices to lead to more equitable, productive disciplinary engagement.

Becoming a STEAM-Teacher: Co-Construction of a Zone of Proximal Identity Development to Support Program Implementation

Kristina M. Stamatis, Ishita Pradhan, William R. Penuel
stamatis@colorado.edu, Ishita.Pradhan@colorado.edu, william.penuel@colorado.edu
University of Colorado Boulder

Abstract: Exploring the role of teachers' *identities* in their appropriation of the goals, strategies, and materials of STEAM programs, we argue that teachers' "practice-linked" identities (Nasir & Hand, 2008) are consequential for implementation of STEAM programming. We analyze a STEAM program implementation that has shown promise for developing students' interests in STEAM-related futures. We explore how variation in implementation depends upon a *zone of proximal identity development* between program support staff and teachers.

Major issues

Just as they are important for student learning in disciplines, teachers' "practice-linked" identities (Nasir & Hand, 2008), we argue, are important in teaching diverse groups of students to develop STEAM interests and skills. In this paper, we explore how implementation success in MAKE depends upon the construction of teachers' *zone of proximal identity development* (ZPID). We ask the following questions: 1) How do teachers who express using the MAKE program successfully describe their identities with regard to STEAM? and 2) How do STEAM teachers work with program partners to develop a ZPID with regard to STEAM programming?

Perspectives

We approached this study with sociocultural perspectives that suggest teachers' identifications impact their pedagogical approaches (Luehmann, 2016). We see teachers as learners developing new "trajectories of identification" (Polman, 2010) as they engage in new experiences and work to appropriate new pedagogical tools. In order to build understandings around the trajectories that lead to feelings of success with STEAM programming, we draw upon Polman's (2010) notion of the zone of proximal identity development (ZPID). Polman (2010), citing Vygotsky (1978), suggests that identities develop socially in conjunction with cultural tools and practices. ZPID includes the trajectories of identity that an individual can see as possibilities for themselves given the ways they currently identify. We see teachers as potentially embodying trajectories of identity as a "STEAM teacher" in which they describe themselves as experts, learners, or novices in STEAM skills and programs.

Methods and data collection

MAKE (pseudonym) is an interest-driven approach to STEAM learning that can be implemented with students across grades. As the program expanded, the project team has sought to engage and support teachers with a variety of backgrounds in successful facilitation. Our evaluation focused on the conditions and processes that might explain variation in whether and how MAKE was taken up by educators. Our participants included 31 teachers who facilitated the MAKE program during the 2019-2020 school year. We drew upon qualitative methods to conduct semi-structured interviews, including questions around enactment, shifts in teaching, and feelings of support from administration and project teams. We then used a process of interpretive thematic analysis that began with topic coding and proceeded to thematic analysis coding (Braun & Clarke, 2006). As themes of teachers' identifications emerged, we refined our coding scheme and performed a second round of coding to examine teachers' articulations of their identities with regard to the MAKE program and to STEAM generally.

Findings

Throughout our analysis, we noted that teachers of the MAKE program identified within one of three broad categories, (1) those who were confident about their implementation of the program (2) those who were frustrated by the program constraints, and (3) those who expressed feeling insecure about their implementation.

Identifying as an expert with MAKE

Andrea was a STEAM teacher at a STEM magnet school. Andrea described herself as an expert who offered STEAM training at the district level and was "always looking for new resources." Andrea saw herself as both a STEAM *and* a MAKE specialist. Andrea explained that the program filled a gap in curriculum for her students. Because of her expertise, Andrea's administration positioned her as an instructional coach, supporting other teachers co-teaching with a variety of STEAM resources across disciplines. For Andrea, the MAKE program was essential because it allowed her to support other teachers in developing the identities they needed to successfully integrate STEAM skills in their classrooms. Although Andrea had already positioned herself as an expert, she also identified within our interview as a learner and coach and was therefore able to envision a trajectory of identity that could change to incorporate MAKE as part of her identification as a STEAM teacher.

Identifying as an enthusiastic learner of MAKE

Fred's perspective was the common in our interviews. He described himself as a content area teacher who had become the "tech teacher." He went on to explain that he felt "definitely isolated" as the only STEAM teacher in his school. While time constraints meant that Fred did not engage much with the online communities that the MAKE team has established, he expressed feeling confident knowing that a community of practitioners were using the same materials. He also noticed differences in his students' learning that he attributed to MAKE. "They're capable of doing things they didn't think they were before…I can mess up, but I can also learn how to do something in the long run." Fred could see himself becoming a stronger teacher by using the program and hoped he would get to continue to incorporate MAKE program in the future. While not yet expert, Fred was able to co-construct with a community of practice supporting his learning how to engage students with MAKE a ZPID that allowed for feelings of success with the program, even during the pandemic.

Identifying as unsuccessful with MAKE

Mia explained that the MAKE program was new to her advisory classroom. When asked about her context, Mia described the MAKE program as an administrative mandate. Mia explained that she did not feel she had time to develop expertise with the program because the advisory period was intended to introduce students to so many concepts including the MAKE program. Mia acknowledged that although the training she attended had been "really helpful," she did not feel the support she wanted from her school community. "I think that's a real challenge for kids...Because it feels just like something extra that they're doing." She explained she did not have time to engage her students with the program and therefore struggled to identify with its principles and mission. For Mia--in contrast to Fred--the community of practice and support from program partners in how to implement the program was not sufficient as a means to develop a ZPID as a successful MAKE teacher.

Discussion and implications

These cases are representative of the broader themes across our data. Throughout our data analysis we noted that teachers who positioned themselves as "expert" with STEAM were less likely to adopt identities as MAKE teachers, unless they were supporting others. Teachers who had little experience with STEAM or whose settings did not provide support, struggled to position themselves as successful with the program. Teachers who expressed feeling most successful were those who had enough background in STEAM to develop trajectories of identity that allowed them to first imagine themselves as successful, but whose knowledge was also extended with the content in the MAKE program. Our data analysis illustrates the ways that teachers may need support in fostering a ZPID in order to successfully see themselves as knowledgeable in and capable of teaching STEAM. The degree to which they are able to do so is highly contingent on both their own goals and on their ability to co-construct with partners and communities of practice a means to learn to use STEAM tools to support student engagement and learning.

Design-Centered Research-Practice Partnerships as a Means to Promote Multidimensional Transfer among In-Service Teachers

Noam Malkinson, Yael Kali, Yotam Hod
noammalkinson@gmail.com, yael.kali@gmail.com, yotamhod24@gmail.com

Abstract: One of the important outcomes of Research-Practice-Partnerships (RPPs) is the development of an infrastructure that enables professional learning communities to sustain their designed innovations over time. Using a design-centric model of RPPs, this research uses ethnographic methods to characterize such partnerships, and assesses the level of transfer on various dimensions in pedagogical field application, as well as changes in participants' perceptions and sociocultural changes to indicate how they apply their new knowledge in different domains.

Research rational

This research examines a special model of Research-Practice-Partnerships (RPPs) between schools and academia, with the goal of promoting pedagogical change and sustaining these innovations over time. Although there is emerging scientific knowledge about the use of RPPs in education, there is scarce knowledge about the impact and outcomes of these collaborations (Fishman et al., 2013; Kali et al., 2018). One of the important outcomes of RPPs is the development of an infrastructure that enables the school to sustain the designed innovation over time. To understand the impact of these RPPs, this research is organized into two stages. The first stage focuses on deepening the understanding of the nature of the RPPs, by characterizing them by means of interactions within each partnership, participants' considerations, dynamics, and their ongoing and changing perceptions of the partnership. This stage is based on Kali et al.s' (2018) model of a design-centric RPP (DC-RPP) approach, which identifies two lenses: one lens which focuses on RPPs in the context of full-school pedagogical change; and the second lens which focuses on a specific discipline, evolving and progressing into innovative course designs. The second stage of this research examines the way educators develop knowledge during RPPs and apply it in different contexts. This stage is based on Dori and Sasson's (2013) transfer model, which evaluates whether and how innovative knowledge is assimilated by educators so it can sustain over time. Therefore, assessment at this stage involves levels of transfer on various dimensions, in pedagogical field application, as well as changes in participants' perceptions and possible sociocultural changes to indicate how they apply their new knowledge in different domains. Understanding similarities and differences of DC-RPPs between the two lenses and then assessing for sustainability of the innovative knowledge acquired during the DC-RPP is vital to better understand the mechanisms underlying effective RPPs, which is the aim of this research.

Background

Professional learning communities and RPP models

Pedagogical changes within schools can be incredibly complex, and there is a need to adjust to the specific needs found within the local context of the school itself (Fishman et al., 2013). One common model for leading school pedagogical change is by building professional learning communities (PLCs). Teachers in PLCs seek continuous improvement as they tentatively explore new ideas and concepts to build shared knowledge (Hod, Bielaczyc, & Ben-Zvi, 2018). In recent years, RPPs have emerged alongside PLCs to promote pedagogical changes in schools and advance research (Coburn & Penuel, 2016). Since partnerships between educational researchers and educators involves participants from varied professional backgrounds with different vocabularies, work practices, and communication structures, developing productive partnerships requires special attention (McKenney & Brand-Gruwel, 2018). Structuring the partnership with clear roles and norms is important to forge trusting relationships, a process which involves effective communication and shared meaning making between the participants (Kali et al., 2018). Scholars have identified different research traditions relevant to RPPs, one of which is the design-based implementation research approach, which examines how interventions are effectively implemented in a broader environment by doing research *with* the teachers rather than *for* the teachers (Fishman et al., 2013). Drawing on this idea, Kali et al's (2018) notion of DC-RPPs focuses on the development of the RPP design, with an emphasis on a recognized theory or approach and by paying attention to the dynamics of the partnership, along with the intention that the school staff to sustain the innovation over time (Kali et al., 2018). This model relies on a theory-practice matrix which produces design principles to guide a productive and innovative process, by overlapping theory lenses with practical constructs. This model can be assimilated in either of the RPP lenses, whether it involves an entire school vying to make a wide-ranging pedagogical transformation, or in the case of designing specific courses in a particular discipline. A powerful tool for assessing continuous improvement and successful assimilation of pedagogical changes within school is to measure transfer skills multidimensionality among practitioners (Dori & Sasson, 2013), as well as to accompany the course of the pedagogical change by ongoing assessment and evaluation processes (Sasson & Dori, 2012).

Measuring sustainability of DC-RPPs through transfer skills

The acquisition of knowledge in one context, internalized through practice and finally applied to a new context, is defined as the transfer of learning (Dori & Sasson, 2013). According to Dori and Sasson (2013), transfer has various dimensions within the categories such as task distance, interdisciplinarity, and skill set. It is therefore of great importance to measure the level of transfer multidimensionally to evaluate educational success. Hence, an assessment process based on transfer that follows the formation and activity of PLCs during pedagogical changes within schools can be of great value to determine the outcomes of DC-RPPs (Akkerman & Bruining, 2016).

Research questions and method

The questions motivating this research include: (a) What are the characteristics of the ways that DC-RPP-based PLCs develop? (b) To what degree and in what ways do the DC-RPPs enhance and contribute to transfer skills among participating teachers so they will be sustainable over time? To answer these questions, I am examining similarities and differences in a multi-dimensional comparison between two settings of RPPs: i) a structured whole-school pedagogical change; and ii) a specific innovative design within a school framework. Each RPP setting is composed of 3-5 schools, of whom the participants are educators and researchers from academic institutions. This research uses an evidence-based, mixed-methods research and analysis approach, integrating both qualitative and quantitative data from interviews, questionnaires, and observations.

Expected contribution

Most research on RPPs emphasizes the interventions developed during the partnerships rather than investigating the impact of the partnership outcomes over time (Coburn & Penuel, 2016). The overall goal at the end of the partnership process is to reach the continuation of the school's generative process independently and in accordance with its vision. Since intra-school and regulatory characteristics create a dynamic school agenda, examining pedagogical changes over time and measuring their sustainability is possible by assessing transfer skills among teachers. Therefore, this research could shed light on this vital facet of RPPs, adding new knowledge to the ways they play out as well as how to measure the effectiveness of different approaches.

Learners' Adjustment Strategies Following Impasses in Medical Simulations - Effects of Prior Knowledge

Nicole Heitzmann, LMU Munich, Germany, nicole.heitzmann@psy.lmu.de

Abstract: In this study we analyze how learners with different prior knowledge use different adjustment strategies (reflective or evidence generation) after impasses and how that affects their learning in a simulation in medical education. We found that learners with medium and low prior knowledge used evidence generation more often. Only learners with medium prior knowledge benefited from further evidence generation. Therefore, adjustment strategies seem to have differential effects depending on learners's prior knowledge.
Keywords: simulations, medical education, impasse, adjustment strategy, prior knowledge

Problem statement

Simulations are a very effective form of learning (Chernikova et al., 2020). However, it is unclear what makes simulations to one of the most effective learning environments in higher education. An open question is if learners with different prior knowledge make use of the additional adjust strategies a simulation offers after the experience of an impasse and if that kind of adjustment improves their learning.

Theoretical background

In different approaches learning from impasses is an important element (e.g. Kolodner, 1983). The experience of an impasse can lead to reflections and therefore triggers a deeper understanding (VanLehn, 1999). In more recent approaches, the experience of an impasse is considered a productive failure, preparing learners for future learning (e.g. Kapur, 2014).

Possible adjustment strategies in simulations are re-inspecting previously presented information and generating further relevant evidence, trial and error, or taking time to reflect without or with less time-pressure. In connection with simulations and the experience of impasses these strategies are not systematically investigated yet. It seems likely that learners with different prior knowledge at a different stage in their expertise development use different adjustment strategies during learning with simulations. However, it is unclear what kind of adjustment strategies learners with different prior knowledge show after they experience an impasse in a simulation and subsequently what kind of scaffolding they would need to improve the quality of their learning process.

Research questions

H1: Learners with high prior knowledge are more likely to use a reflective adjustment strategy after they experience an impasse whereas learners with low and medium prior knowledge are more likely to use a strategy of further evidence generation in a simulation.
H2: Learners with high prior knowledge use more time to reflect after they experience an impasse in a simulation.
H3: What can be learned from the adjustment strategy of evidence generation following an impasse depends on a learner's prior knowledge in a simulation.

Method

For the purpose of our study we used a simulation in medical education in which participants diagnosed fictitious patients (see Radkowitsch et al., 2020). In the simulation learners get access to five patient files. Learners are asked to formulate a request for a radiological diagnostic procedure for each patient to a fictitious radiologist. Learners who justify their diagnostic request appropriately receive a report of the radiological findings. Other learners get a feedback in which the fictitious radiologist asks for further justification. Afterwards learners can either decide to go back to the patient files and generate further evidence or getting the examination without generating further evidence only using internal resources to solve their impasse. We counted both reactions and logged the time between the feedback and the subsequent reaction of the learner. Depending on the correctness of the final diagnosis learners received 0, 0.5, or 1 point. We used a quasi-experimental one-factorial design with learners on three levels of prior knowledge (low (N=45) -medium (N=28). -high (N=25)).

Results

Relative to the absolute number of impasses, learners with high prior knowledge used approximately to the same amount an adjustment strategy of evidence generation (48.1%) and a reflective strategy. Both learners with intermediate (70.1%) and with low prior knowledge (66.1%) used an adjustment strategy with further evidence generation more often. This partially confirms Hypothesis 1.

Regardless of whether a strategy of further evidence generation was used ($F_{2,179} = 4.24$; $p = .016$; $\eta^2 = .045$) or a reflective strategy was used ($F_{2,139} = 2.88$; $p = .030$; $\eta^2 = .040$), learners with high prior knowledge took the most time before taking their next action after they encounter an impasse. This is in support of Hypothesis 2.

To test Hypothesis 3, we defined a step-wise logistic regression model with both frequency of evidence generation strategy and the level of prior knowledge predicting the likelihood of an accurate diagnosis. Both the main effect for the frequency of evidence generation strategy ($b = -.99$; $p = .013$; $OR = 0.37$) and the difference between learners with intermediate and high prior knowledge ($b = -1.86$; $p = .008$; $OR = 0.16$) as well as the difference between low and high prior knowledge ($b = -1.41$; $p = .024$; $OR = 0.25$) were significant. In line with Hypothesis 3, though, there was a significant interaction between the both predictors. The likelihood of an accurate diagnosis decreased with a higher frequency of the adjustment strategy of evidence generation for learners with high and with low prior knowledge whereas it increased for learners with intermediate prior knowledge.

Discussion

In simulations different adjustment strategies after the experience of impasses than in real-life practice are feasible. The findings of the present study can be interpreted in a way that the same adjustment strategy following an impasse can be helpful for specific learners but have negative consequences for learners with other learning prerequisites.

Similar to other approaches (e.g. Kolodner, 1983; VanLehn, 1999) also in simulations reflective adjustment strategies seem important, at least for learners with high prior knowledge. Learners with low and intermediate prior knowledge, however, do benefit to a much lesser extent. Learners with low prior knowledge also were not able to benefit from the adjustment strategy of generating further evidence. Maybe instead of generating meaningful evidence they fell back to a trial and error strategy.

For learners with a medium level of prior knowledge an adjustment strategy of evidence generation following an impasse seems helpful for an accurate diagnosis during their learning process. Maybe only with an intermediate knowledge structure, learners are to identify knowledge gaps and to close that gaps with the additionally generated evidence.

To conclude, simulations can provide learning opportunities not sufficiently present in real life professional situations. They, for example, leave phases for reflection and enable to re-inspect and retry repeatedly. This study found that most of the learners make use of these additional opportunities. However, the taken opportunities have differential effects on learning, depending on the learners' prior knowledge.

Exploring Teachers’ Perspectives on Epistemic Growth

Shiri Mor-Hagani, Sarit Barzilai
shiri.mor@edtech.haifa.ac.il, sarit.barzilai@edtech.haifa.ac.il
University of Haifa

Abstract: In this study, we used the Apt-AIR framework (Barzilai & Chinn, 2018) to explore the nature of teachers’ epistemic growth through the eyes of practicing teachers. We analyzed teachers' learning journals throughout a course on digital literacy and identified reflections on epistemic growth. Teachers reflected on growth in all aspects of epistemic performance described by the Apt-AIR framework. We also found that teachers reflected on growth in both epistemic performance for learning and in teaching.

Introduction

Recent research on epistemic thinking in the learning sciences has argued that conceptualizations of epistemic thinking should encompass a more diverse range of epistemic practices and attend more to the practical and social nature of epistemic thinking. In light of these observations, Barzilai and Chinn (2018) proposed the Apt-AIR framework which foregrounds learners’ epistemic competence to successfully achieve epistemic aims across diverse situations and contexts. This framework is based on the AIR model which posits that epistemic thinking includes *epistemic **A**ims and value, epistemic **I**deals* and ***R**eliable epistemic processes*. The Apt-AIR framework further identifies five interweaving aspects of competent engagement with epistemic aims, ideals, and processes: (1) cognitive engagement in epistemic performance; (2) adapting epistemic performance to diverse situations and contexts; (3) metacognitively regulating and understanding epistemic performance; (4) caring about and enjoying epistemic performance; and (5) participating in epistemic performance together with others. Promoting epistemic growth, according to the Apt-AIR framework, requires attending to all of these aspects. However, the implications of this approach to understanding teachers' epistemic growth have not yet been examined.

Buehl and Fives (2016) argued that teachers' epistemic thinking relates both to learning and to teaching. In *epistemic thinking for learning*, teachers focus on their *own* ways of knowing and on achieving their own epistemic aims. In *epistemic thinking in teaching*, teachers primarily focus on helping students achieve epistemic aims. In this study, we wished to examine whether Buehl and Fives' (2016) distinction between epistemic thinking for learning and in teaching might apply to teachers' epistemic growth. We examined the following questions: (1) Which aspects of epistemic performance are described in teachers’ reflections on epistemic growth? (2) Do teachers reflect on growth in epistemic performance for learning as well as in teaching in each of these aspects?

Method

The context of the study was an online course on digital information literacy. Participants were a heterogeneous group of 27 practicing teachers with 2 to 18 years of teaching experience in various grade levels and subject areas.

The course included four components that were collectively intended to promote epistemic performance: (a) *Reading and reading discussions* - Teachers read articles and participated in asynchronous discussions about them; (b) *Reflective experience tasks* - Teachers engaged in various tasks that involved searching, evaluating, and integrating online information sources. Teachers then evaluated their strategies and criteria for performing these tasks, individually and in small groups; (c) *Reflective journals* - Teachers wrote four journal entries in which they considered their beliefs regarding epistemic issues and their learning experiences; (d) *Design task* - Teachers collaboratively designed instructional units fostering digital literacy criteria and strategies in disciplinary contexts.

We used teachers' journals as our primary source of data. To validate and triangulate our findings, we conducted retrospective interviews with nine teachers. We developed a coding scheme to capture descriptions of growth within each of the Apt-AIR aspects. These descriptions were coded as growth in epistemic performance *for learning* when teachers reflected on changes in competence to achieve their own aims, and as growth in epistemic performance *for teaching* when teachers described growth in teaching plans or practices that were intended to foster learners' competence to achieve aims. The interrater reliability was Cohen's Kappa 0.77-1.00.

Results

Teachers described growth in epistemic performance for learning and in teaching in all five aspects (see Table 1). Growth in cognitive, metacognitive, and caring about epistemic performance was described by all or most of the teachers. Growth in adaptivity of and participation in epistemic performance was mentioned less often than other aspects, all *ps* < .001-.005. Additionally, growth in cognitive performance was described more in the context of teaching than of learning, $p = .012$; whereas growth in metacognitive performance and in participation in epistemic performance was described less in the context of teaching than of learning, $p = .001$ and .021, respectively.

Table 1: Percentages of Teachers Who Described Growth in Each Aspect in the Reflective Journals

Aspects of Epistemic Performance	Growth in Epistemic Performance for Learning	Growth in Epistemic Performance in Teaching	All Mentions
Cognitive engagement	55.6%	88.9%	92.6%
Adapting epistemic performance	18.5%	14.8%	25.9%
Metacognitively understanding and regulating epistemic performance	100.0%	59.3%	100.0%
Caring about epistemic performance	74.1%	77.8%	92.6%
Participating in epistemic performance	44.4%	14.8%	48.1%

(1) Growth in cognitive engagement in epistemic performance. Teachers expressed growth *for learning* when they described changes in their own abilities to apply strategies or criteria to achieve epistemic aims, e.g., "I pay attention to the writer's expertise, the websites' background, accuracy and credibility" (Loren, J(=Journal)3). Expressions of growth *in teaching* included descriptions of changes in plans to support students' use of epistemic criteria or strategies, e.g., "I will try to lead students to use criteria as a tool for evaluation" (Carly, J4).
(2) Growth in adaptivity of epistemic performance. Growth in adaptivity *for learning* was expressed in awareness that application of criteria and strategies depends on various factors, e.g., "[the tasks] illustrated different circumstances and approaches to the same strategy depending on the information we locate" (Bella, J4). Growth *in teaching* involved awareness that learners need to perform in diverse contexts, e.g., "I will intertwine the strategies in many disciplines to allow learners to transfer the strategy to different contexts" (Mika, J4).
(3) Growth in metacognitive understanding and regulation of epistemic performance. Growth *for learning* was reflected in changes in understanding of epistemic criteria and strategies, e.g., "I learned that every information search starts with inquiry into and sorting of information sources" (Carly, J2), as well as growth in regulation, e.g., "I learned… to metacognitively observe how I investigate and construct knowledge" (David, J3). Growth *in teaching* was evident when teachers referred to supporting students' metacognitive understanding or regulation, e.g., "I want to assist them to develop their control skill" (Lisa, J4).
(4) Growth in caring about epistemic performance. Growth in caring *for learning* was evident in appreciation of the value of using ideals and processes to achieve epistemic aims, e.g., "I now believe in the importance of evaluating knowledge sources in all areas of my life" (Julia, J3). Growth *in teaching* was reflected in references to the importance of promoting students' performance and of fostering students' motivation to engage in epistemic performance, e.g., "Raising awareness of the possible dangers is the first step in my opinion…" (Annabeth, J4).
(5) Growth in participation in epistemic performance with others. Mentions of growth *for learning* involved reflections on the social nature of epistemic performance, e.g., "I am learning to see online information from different perspectives" (Marisa, J2). Reflections on growth *in teaching* included description of how teachers would foster their students' social participation in epistemic performance, e.g., "We will create together criteria for searching for information on the Internet" (Rachel, J4).

Discussion
This study demonstrates that teachers' epistemic growth is multi-faceted and involves co-evolving changes in capabilities and tendencies to actively use epistemic ideals and processes in the pursuit of epistemic aims, to adapt epistemic performance, to metacognitively understand and regulate this performance, to care about it, and to participate in epistemic performance together with others. Further, teachers' epistemic growth was found to involve intertwined changes in epistemic performance for learning as well as in teaching. Nonetheless, growth in adaptivity of epistemic performance and in social participation in epistemic performance were described by relatively few teachers. These aspects may be more challenging to grasp and might require focused attention. Despite these challenges, this study suggests that promoting teachers' epistemic growth along all aspects of the Apt-AIR framework is feasible in teacher education.

Epistemological Understanding of History in Lower Secondary Education, and its Influence on Historical Reasoning Skills

Iris Hulders, Michiel Voet, Bram De Wever
Iris.Hulders@UGent.be, Michiel.Voet@UGent.be, Bram.DeWever@UGent.be
Tecolab, Department of Educational Studies, Ghent University

Abstract: Although epistemological understanding plays a major role in students' reasoning, limited research is conducted on this topic. Hence, we examined the epistemological understanding of history of 942 students in lower secondary education using a pencil-and-paper test, and its influence on their historical reasoning skills. Results show that only half of the students have an advanced epistemological understanding and that epistemological understanding has a significant influence on a number of core historical reasoning skills.

Keywords: historical reasoning skills, epistemological understanding of history

Theoretical background

Students' epistemological understanding of history can be defined as their insight into the nature and construction of historical knowledge (Kuhn et al., 2000). Studies generally distinguish between three levels of epistemological understanding; the absolutist, multiplist, and evaluativist level (see, Voet & De Wever, 2016). At the *absolutist* level, students associate history with a search for an absolute truth. At the *multiplist* level, students understand that there may exist different interpretations about a historical event but perceive those interpretations as equally correct. At the *evaluativist* level, students also acknowledge the existence of different interpretations in history, but in addition, they are aware that some have stronger evidentiary support than others. This kind of nuanced epistemological understanding is an essential prerequisite for students' historical reasoning skills, as different studies have shown that epistemological beliefs influence students' academic performances (Stoel et al., 2017).

Although the comparison of historical sources and the way argumentation is constructed, depends on students' epistemological understanding (Kuhn et al., 2000; Voet & De Wever, 2016), there is a lack of research that investigates students' epistemological understanding and how it affects the different core historical reasoning skills of students. Historical reasoning can be seen as the act of reasoning with historical information (van Drie & van Boxtel, 2008) and consists of different components. In this contribution, we will use the framework of Voet and De Wever (2017) which outlines five core historical reasoning skills that are required to draw conclusions on historical information: (1) sourcing, (2) appraising, (3) specifying, (4) constructing, and (5) arguing. Here, we will focus on sourcing, appraising and arguing as those historical reasoning skills can be measured using a pencil-and-paper test. *Sourcing* is checking the nature of a source, by considering the author's background and credentials, period of the source production and type of the source. *Appraising* requires assessing the content of a source, by evaluating the author's perspective, reasoning and evidence, and requires comparing information across sources. *Arguing* means to formulate and weigh arguments in support of different conclusions (Voet & De Wever, 2017).

The main aim of this study is to investigate students' epistemological understanding of history and its influence on the core historical reasoning skills sourcing, appraising, and arguing.

Method

Participants

This contribution is situated within a larger research project that aims to investigate the impact of an inquiry lesson unit for history in the second year of Flemish (Belgium) secondary education. 942 students from 52 classes in 23 schools participated. This sample consisted of 525 boys and 417 girls. Their average age was 14 (SD = 0.45).

Instruments

Data were collected through a pen-and-paper test during the history-lesson, under the supervision of the teacher. Prior to the data collection, the teacher received a training about how to collect the data. Students had 50 minutes to complete the pen-and-paper test and they completed the test anonymously.

The first part of the test contained three authentic historical sources about the death of Emperor Claudius. In each source, information about the author and the context was given. After reading the sources, students had to assess the value of each source (*sourcing* and *appraising*) and had to give a substantiated answer to the question "Was emperor Claudius murdered by order of his wife? Explain why you think he was or wasn't." (*arguing*).

For the second part, a paper-and-pencil instrument that Kuhn et al. (2000) used to measure epistemological understanding, was adapted. This original instrument presents students with two contrasting claims about the nature of knowledge across different domains. After reading the claims, students are asked to judge whether only one claim could be right, or both could be correct. Students who opt for the latter, are asked whether they believe that one judgment might be regarded as having more merit than the other or both claims are equally correct. To fit the original instrument in the context of history, students were presented with two claims that were firmly embedded in a research on Emperor Claudius (see above). First, students were asked to read the sources. Then, they read the two opposing claims based on the authentic sources. Finally, students judged the claims and argued what the existence of such different claims meant for decision-making in historical research.

Data-analysis
To answer the research question, frequencies of all variables were calculated, and a multivariate regression was carried out with sourcing, appraising, and arguing as dependent variables and epistemological understanding as fixed factor. Dependent variables were scored from 0 to 2, using a rubric and this data was blind double-coded.

Results and discussion
Looking at students' epistemological understanding of history, most students (51.70%) are evaluativists (n = 487), 35.90% are absolutists (n = 338) and 12.40% are multiplists (n = 117). This suggests that only half of the students in lower secondary education acknowledge the existence of different interpretations in history, and are at the same time aware that some interpretations have stronger evidentiary support than others. This is in line with other research that shows that students often see history as fixed and equate history with the past (Stoel et al., 2017).

Looking to *sourcing,* students' epistemological understanding seems to have a significant effect ($F_{(2, 939)}$ = 4.73, p=.009) on their sourcing competencies. More specifically, *absolutists* (M=0.14, t_{939}=-2.20, p=.028) and *multiplists* (M=0.10, t_{939}=-2.68, p=.008) seem to score significantly lower on sourcing competencies compared to evaluativists (M=0.19) who have a more nuanced epistemological understanding.

On appraising, only *absolutists* (M=0.19) have significant lower results (t_{939}=-2.01, p=.038) compared to evaluativists (M=0.23). Being a *multiplist* (M=0.21) showed a non-significant negative relation with the appraising capabilities (t_{939}=-0.86, p=.39) compared to evaluativists. This means that only students who associate history with a search for an absolute truth (absolutists) assess the content of a source significantly worse, compared to students who acknowledge the existence of different interpretations in history (evaluativists).

As to *arguing*, only *multiplists* (M=0.21) have significant lower results (t_{939}=-2.16, p=.031) compared to evaluativists (M=0.25). Being an *absolutist* (M=0.23) showed a non-significant negative relation with arguing capabilities (t_{939}=-1.33, p=.18) compared to evaluativists.

In sum, students' epistemological understanding of history seems to have mainly a significant effect on the core historical reasoning skill *sourcing* and a differentiated effect on *appraising* and *arguing.*

Theoretical and educational significance
Only half of the students in lower secondary education are evaluativists and therefore only 52% probably possess an essential prerequisite for historical reasoning. Moreover, differences in epistemological understanding can partially explain the differences in students' core historical reasoning skills. So altogether, it can be argued that more explicit attention for students' epistemological understanding in history is needed (Stoel et al., 2017).

Searching for Instruction: Practices and Trajectories in the Selection of Online Video Tutorials

Thomas Hillman, University of Gothenburg, thomas.hillman@gu.se
Oskar Lindwall, University of Gothenburg, oskar.lindwall@gu.se

Abstract: The search for digital resources is a central starting point for many learning processes. Building on previous research on search queries, this study maps the trajectories of users searching for online video tutorials. The data consists of video recordings of 61 sessions that included a laptop with a web browser along with the materials needed to complete an instructed activity. The study focuses on the activity that took place between the initiation of the first search query and the actual instruction following. The results demonstrate a) the practices of selecting online instructional videos, and b) how these practices form trajectories of activity. The selection process was often extended involving several steps after the initial search term had been formulated. The study concludes with a discussion of how technical developments might support the search and selection of online videos produced for the learning and achievement of practical tasks.

Introduction

Online video tutorials have become a massively prevalent social and pedagogical phenomenon. The popularity of these tutorials can be partly understood in terms of innovations in the production, distribution, and consumption of video. Whether someone wants to find instructions for how to bake a particular cake, cut their dogs hair, or change the oil filter on their car, there is almost certainly several videos that show them how. Given the enormous number of videos that are available, a central concern is finding a tutorial that matches the skills of the user and the requirements of the task. Instead of having an instructor adapting to the needs and competence of the novice, the use of video tutorials necessitates that the user finds the appropriate instructions themselves. In the context of self-directed learning, search engines are not only used to find news sites, encyclopedias and journals. Instead, video-sharing platforms like YouTube are often a key resource that in contrast to sites like Wikipedia, with its library of information, act as massive libraries of skills and practices.

The literature on online search tasks testifies to the important relationship between what is searched for and how it is searched (e.g., Gerjets, Kammerer, & Werner, 2011; Zhang & Capra, 2019). Widely used search technologies are often designed for a specific media type or platform, but not developed to meet the specific needs of a user searching for a particular type of content in a given type of media. The aim of this paper is to map the practices of people selecting online instructional videos and to examine how technical features might be better adapted to or developed for supporting the selection process. To do this, the study addresses the following empirical questions:

- What are the practices of selecting online instructional videos?
- How do the practices of selection form trajectories of activity?

Methods

To map the trajectories of users selecting online instructional videos, this study draws on a corpus of 61 video-recorded sessions. These sessions were collected as part of two different data collection initiatives where the majority (54) were conducted during a science festival. Participants had a laptop with a web browser at their disposal along with the material needed to complete the instructed activity they had chosen. They had free choice of which instructions they followed and where they looked for them. The screen of the laptop was captured along with video-recordings from the laptop's webcam and video cameras arranged so that the practical accomplishment of the instructed activity could be recorded.

Analysis of the video corpus involved several steps intended to map the instructional video selection processes of participants and focused on the activity that took place between the moment participants started writing their first search query either directly on YouTube or through Google search and the moment when they started playing the video during which they completed the task. Each selection sequence was subdivided into selection moments with start-time, end-time, number of search queries entered, number of rollover previews triggered, and number of videos played recorded. Relationships within this data were then examined in terms of selection process features using an exploratory data analysis approach (Morgenthaler, 2009) to identify recurring patterns and significant features of relevance.

Results

With the aim to map the trajectories of people looking for instructional videos and to examine how technical features might be better adapted to or developed for supporting the selection process, the findings of this study examine the selection process features engaged in by participants and the time taken to make selections.

Of the selection process features examined, the number of selection moments, search queries produced, and videos played correlate with each other, indicating that the more selection moments a user has the more search queries they produce, and the more videos they play. It is also clear that participants whose selection process included more than one moment tended to select from their earlier search results or from recommended video lists before returning to producing new search queries in later moments. One selection process feature that did not correlate strongly with the others was number rollover previews. This feature involves a user pausing the cursor over the thumbnail image for a video in the search results or recommended video lists. While the cursor is paused, a preview plays in the thumbnail indicating that the user is evaluating that video. The data shows that users tend to activate more rollover previews the more selection moments they engage in and that when a selection moment included the production of a new search term, it tended to include less triggering of rollover previews than a moment that did not.

A major factor in the variability in amount of time that was dedicated to assessing videos at each selection moment was the type of task for which instructions were being sought with participants seeking instructions for *crafting* a basic origami figure or balloon animal taking less time to find the video they would follow than those looking for instructions for how to *repair* something. For the crafting tasks it was relatively simple for participants to relate the material conditions they had with a piece of paper or balloon to those shown in instructional videos. For the repair tasks that included bicycle repair, picking locks, and tying knots, there was significantly more complexity and variability in the material conditions participants had in front of them in relation to those shown in videos.

Discussion

This study has traced the activity of users from the start of their selection process until their choice of a video instruction to follow is made. The results show how the selection and playing/scrolling of videos are two separate but integrated moments in searching for an online video. When participants did not select their final video from the results of their first search query, most individuals or collaborating groups selected their final video from subsequent search query results and only a few from the recommended video lists. This suggests that the recommendations made by the platform for related videos may not have been particularly useful to participants. By increasing content awareness for instructed activities, recommendations could present alternative takes on the same task, rather than other videos by the same producer or other videos other people have looked at.

For a video platform like YouTube, there is often a substantial number of videos available for every task, but very little in the way of help for delineating the differences in specific characteristics that would allow the matching of a users' material situation to those shown in a video (see also Torrey et al., 2009). This issue is more critical in some cases than in others. In relation to the material investigated here, for instance, it was more difficult for participants undertaking *Setup/use/repair* tasks to find a suitable instructional video because it was more difficult to match their material conditions for completing the task. To assist the user in finding the right video, a focus on search queries may be less productive than features designed to summarize or inform about the content of videos. In relation to this, the study shows that rollover previews are important, and it would be relevant to explore the possibility of summarizing the steps of the tasks shown by relying on the segmentation immanent in the video (through verbal description, pausing, cuts, etc.).

Evaluating a Historical Video Game: Roles of Gaming Expertise and History Expertise

Naama Goldik, Sarit Barzilai
naama.edri@edtech.haifa.ac.il, sarit.barzilai@ edtech.haifa.ac.il
University of Haifa

Abstract: We invited gamers with various levels of gaming and history expertise to play a historical game, *Civilization,* in order to explore how players evaluate the game. Expert players tended to view the game as half-reliable; whereas history mid-experts tended to view it as unreliable. Players employed diverse epistemic ideals to evaluate the game. This suggests that *Civilization* could be used to engage students in critical reflection and discourse about representations of history in popular culture.

Introduction
Historical games are a highly popular genre of digital games. These games incorporate historical representations that have varied degrees of reliability and accuracy (Chapman, 2016). Because players can spend substantial amounts of time interacting with semi-accurate historical representations in historical games, it is important to understand how they perceive and evaluate the reliability of such games. However, the ways in which players think about the epistemic aspects of historical games have rarely been examined.

This study is part of a larger study in which we examine the epistemic aims, ideals, and reliable processes (Chinn et al., 2014) that players of *Civilization V (Civ)*, a popular historical simulation game, engage with in three layers of knowing: knowing in the game, knowing about playing the game, and knowing about the game as a representation (Barzilai, 2017). Because history expertise has been found to affect how people process, interpret, and evaluate historical sources (Gottlieb & Wineburg, 2012), we wished to examine whether and how history expertise might shape players' epistemic thinking. We also examined whether expertise in playing the game might also influence evaluations of the game. In this contribution, we focus on the following questions: (1) How do players with different levels of gaming expertise and history expertise perceive the reliability of *Civ*? (2) Which epistemic ideals do players use to evaluate the reliability of *Civ*?

Method
We used a 2X2 design that crossed gaming expertise and history expertise. The participants included 23 adult gamers who were purposefully selected so that approximately half had no *Civ* experience, and the other half were experienced *Civ* players. Additionally, approximately half of the participants did not study history beyond mandatory high-school studies, and the other half had an academic degree in history or were studying towards such a degree. We considered this latter group as mid-level history experts because they were not professional historians and yet had developing academic expertise in this discipline. This resulted in four groups of players with: (1) no expertise, (2) *Civ* expertise, (3) history expertise, and (4) both *Civ* and history expertise.

To expose players' thinking, they were asked to think aloud while playing *Civ* for one hour. After playing the game, we conducted retrospective semi-structured interviews about the game. The data were qualitatively analyzed using thematic analysis. The analysis was informed by the AIR model, but the specific aims, ideals, and processes employed by the players were inductively inferred from the data. The first author and a research assistant independently coded a third of the quotes. The Kappa score for interrater agreement ranged from 0.64 to 0.85 (M = 0.73, SD = 0.08). Disagreements were resolved by discussion.

Findings

Views of CIV's reliability
We identified three main views of the game's reliability: About half of the players (47.8%) viewed the game as *half-reliable* (i.e., as partly accurate or credible), some players (39.1%) viewed the game as *unreliable (*i.e., as entirely inaccurate or not credible), and a few (13.0%) said that they found it *difficult to judge* its reliability.

Civ experts tended to describe the game as half-reliable (75.0%) more often than *Civ* novices (18.2%). Civ experts often said that the game can meaningfully represent history despite its unreliable characteristics, e.g., "Even if this game does not represent history in the most reliable way, in my opinion it can be a good tool for teaching history." *Civ* novices often expressed difficulties judging the game's reliability (27.3%), e.g., "I saw only a little, so it's really hard for me to say." Gaming expertise appeared to support complex reliability judgements because of expert players' deep familiarity with various features of the game. This helped expert players know which features were more or less reliable and make nuanced judgments.

Historical expertise appeared to play a different role. History mid-experts viewed the game as unreliable (60.0%) somewhat more than history novices (23.1%). History mid-experts used their knowledge of historical processes, events, and phenomena to criticize the game, e.g., "*It's not just ideologies*, but also the geographical area. It's an imaginary scenario, *there's no historical context.*" In contrast, history novices often described the game as half-reliable (61.5%) and seemed more accepting of its semi-accurate features.

Players with both *Civ* and history expertise coordinated their domains of expertise in different ways. One player viewed the game as pure a-historical fun, e.g., "*The game has no historical truth*." Other players interpreted the game, in light of their understanding of the nature of historical knowledge and of video games, as representing a particular historical perspective or abstraction, e.g., "Everything in history is about processes. So if you simplify it, it's down to what happened and who was the leader, so really *it's very fitting to represent it this way*."

Epistemic ideals for evaluating the reliability of CIV

Participants mentioned two main categories of ideals for evaluating the reliability of *Civ*: (a) *Correspondence* to real-world history based on evaluation of *consistency* with their own historical knowledge, e.g., "I know something isn't reliable when it contradicts something I know"; and (b) the *creators' trustworthiness*, which was mostly evaluated according to intent *to entertain vs. inform,* e.g., "they focus more on entertainment than historical reliability", *expertise,* e.g., "if [the creator] is a famous historian it will add some credit to the [game's] reliability", and *commercial interests,* e.g., "the game's main goal is not teaching history but selling as many copies to as many players possible." Interestingly, all player groups engaged with these ideals in a similar manner and frequency.

Discussion

Experienced *Civ* players viewed the game as half-reliable, acknowledging that some features of the game can represent history, while being critical of other features. This complex view allowed them to perceive the game as meaningful while remaining vigilant regarding its inaccuracies. In contrast, greater historical knowledge led players to be more critical of the reliability of the game. Players with both *Civ* and history expertise navigated this tension in different ways: either by rejecting the historicity of *Civ* or by accepting *Civ* as a type of historical representation that can be "read" as a historical text that reflects a particular historical perspective or abstraction.

To evaluate the game, players engaged with multiple epistemic criteria, relating both to the content of the game and to the trustworthiness of its creators. There were no differences in the criteria used by novices and experts, in contrast to prior studies. It is possible that the tension created by the game's semi-accurate nature prompted players to critically evaluate it.

These findings suggest that historical games can have a twofold contribution: They can inform learners, to some extent, about historical processes, events, leaders, etc., and they can also enable players to engage in critical reflection and discourse about the nature and reliability of historical representations. Learning to critique historical representations in games, and to consider creators' intentions and biases, might help raise learners' awareness of how history is represented in popular culture. More generally, we suggest that because learners are frequently exposed to representations (and misrepresentations) of history, science, and more in popular culture and media, learning to navigate and critique such half-reliable spaces is an important 21st century skill.

The Impact of Interdisciplinary STEM Innovation on the Role Identity of Science Teachers

Pakon KO, Frank Li, and Nancy Law
kopakon@hku.hk, lpcfrank@hku.hk, nlaw@hku.hk
The University of Hong Kong

Abstract: The promotion of K-12 STEM education creates new conditions for science teachers to learn new elements in practice. This learning experience would affect teacher role identity development and hence the subsequent innovation process. This study explores how the innovation of STEM education influences the role identity development of science teachers with a focus on how various aspects of practice that teachers experienced in their school contexts impact on their role identity development.

Keywords: Role identity, interdisciplinary STEM, epistemic network analysis

Theoretical perspectives

Teachers learn and negotiate their identities through experience (Sachs, 2005) that teacher role identity is not static but developmental, subject to change in new conditions. Identity change can be regarded as a teacher learning outcome (Garner & Kaplan 2019). The change of teacher role identity affects how teachers engage in the innovation process and where they want to be as well as the scalability of an innovation (Chee, et al., 2015). Integrating both sociocultural and psychological perspectives in conceptualizing teacher identity, the Dynamic Systems Model of Role Identity (DSMRI) acknowledges the influence of school contexts, culture as well as personal disposition and emotion in teacher role identity development (Garner & Kaplan 2019). Extant literature informs us that teacher role identity might be developed in different dimensions such as leadership and pedagogy, depending on their practice experience. We have a question about how teacher learning in practice in STEM innovation affects their role identity development. This question relates to how teachers position themselves in the innovation and their capacity of taking up and scaling up innovation. This study explores the role identity development of four science teachers' after a year of STEM innovation, drawing on the four major components in the DSMRI model: (1) ontological and epistemological beliefs *("Belief" in Figure 1)*; (2) purpose and goals *(Goal)*; (3) self-perceptions and self-definitions *(Self)*; (4) perceived actions possibilities *(Possibility)* (Garner & Kaplan 2019). The following two research questions guide this study:
(1) What changes in the development of role identity among the four teachers in a year?
(2) How do their changes in role identity relate to their practice experience of STEM innovation?

Method

We used the first-year data from a 19-month government-funded University-school partnership programme which supported project network schools to design school-based STEM curriculum topics with self-directed learning pedagogy (Hew, et al., 2016). Four science teachers, Nick, Lily, Craig and Roy from four different schools in the network were selected for this multiple-case study. All STEM topics they implemented adopted self-directed learning pedagogy and required students to integrate learning elements from two or more disciplines.

We examined individual school conditions for teacher learning through innovation with data generated from pre-post teacher and principal interviews, co-planning and debriefing sessions, and school reports prepared by the University research team. We analyzed how various aspects of practice influenced different teacher role identity components with transcriptions of the pre-post teacher interviews in which there were questions letting teachers elicit their identity aspects and experience of practice. Extracted content for each identity component was examined and categorized in terms of their developmental dimensions. An emerging identity component of "challenges" was added in DSMRI for indicating perceived hindrances or difficulties. Five dimensions for identity development in STEM innovation were identified: (a) *pedagogy ("PG" in Figure 1)*, (b) *discipline (DS)*, (c) *interdiscipline (InterD)*, (d) *professional development (PD)*, and (e) *leadership (LD)*.

The five identity components and the five dimensions formed ten categories for coding for the epistemic network analysis (ENA, Shaffer, et al., 2016). The pre and post interviews formed the two timeframes for comparison (Figure 1). The interpretation was done together with the earlier analysis on individual schools' conditions for teacher learning through STEM innovation.

Findings and conclusion

	Nick	Lily	Craig	Roy
Pre timeframe				Post timeframe				School Team	Cross-subject Science team	Cross-disciplinary team	Cross-disciplinary team	Cross-subject Science team
Specific School contexts	-Nick held responsible to report to the Principal and the academic department about the STEM innovation -The team decided to experience co-teaching in the process	-Lily focused on science learning with the technology teacher supported the making part -The principal and the technology teacher led the STEM innovation	-Craig worked on his own in science classroom only -The vice-principal in the team was the STEM leader not Craig and gave administrative support to Craig when needed	-Roy held responsible to report to the Principal and the academic department about the STEM innovation -Roy was newly appointed as a leader of Science and Technology

Figure 1. The comparison plot for the four teachers, from left to right Nick, Lily, Craig and Roy

The change in the strength of connection between the dimensions for identity development *(PG, DS, InterD, PD, LD)* and role identity components *(Goal, Belief, Self, Possibility, Challenge)* gives indication for their role identity development after a year (Figure 1). In terms of leadership dimension, Lily and Craig did not show any significant development, while Nick maintained and Roy grew stronger. Unlike Lily and Craig, Nick and Roy experienced more interaction mechanisms of monitoring and reporting. Only Lily showed connection between the interdisciplinary dimension (*InterD*) with a role identity component (belief). Her implementation experience in the cross-disciplinary team let her see that interdisciplinary collaboration could satisfy her interest in science learning. It seems the development on disciplinary dimension grows stronger in a cross-disciplinary team.

This study contributes to exploring teacher learning as role identity change in the context of STEM innovation. There are multiple dimensions for teacher development in STEM innovation. The focus on a single dimension such as pedagogy might not be enough to enhance teacher capacity if they need to steer STEM innovation at school. Further research on more cases are needed for seeking the understanding of how certain patterns of school conditions affect identity development and the scalability of innovation.

From "Playful Activities" to "Knowledge Building": A Case Study about a Teacher's Perceptions on the Role of Experiments

Cassia Fernandez, Teachers College, Columbia University, cassia@fablearn.net
Tatiana Hochgreb-Haegele, Teachers College, Columbia University, tatiana@fablearn.net
Paulo Blikstein, Teachers College, Columbia University, paulob@tc.columbia.edu

Abstract: Science education reform initiatives and the integration of maker resources into formal education have the potential to promote new ways of learning. However, well-prepared teachers are central to implement such changes. Using a case study, we describe how the ideas of one teacher about the role of experiments changed as he participated in a PD program. Based on our findings, we suggest strategies for programs aimed at integrating makerspaces resources into science curricula.

Introduction

Significant efforts have been employed to develop and implement new science standards that emphasize not only conceptual knowledge but also the practices of science and engineering. At the same time, makerspaces are becoming increasingly popular in schools, and the new resources they provide can make science learning more aligned with such practices. However, effective makerspace integration into science learning depends not only on the available resources and standards but, most importantly, on teachers prepared to implement new approaches. Student learning and sensemaking come from the productive cognitive effort afforded by well-designed activities, and not solely from the engagement in hands-on experimentations or demonstrations (Duckworth et al, 1990; Furtak & Penuel, 2019). Thus, the integration of makerspaces into school curricula must be accompanied by professional development focused on using maker resources not just as ways to "entertain" or motivate students, but to engage them in meaningful and authentic learning experiences.

As part of a larger effort to reform science education in a medium-sized Brazilian city, we developed a professional development (PD) program for science and makerspace teachers based on two principles: (1) the redesign and implementation of curricular units, as research has shown that changes in teachers beliefs and attitudes usually happen *after* they experiment new teaching approaches and notice the results on students learning (Guskey, 1986), and (2) three iterative cycles where teachers could progressively incorporate new ideas and implement changes based on their experiences in previous cycles, as it has been shown that teachers changes are cyclical and complex processes with interactions between multiple domains (Clarke & Hollingsworth, 2002). Activities in the PD program included workshops, co-design sessions between teachers and researchers, support for classroom implementation, and reflective meetings. Here, we analyze the process of change of one teacher, investigating how his ideas about the role of experiments were transformed as he participated in the program.

Methods

In this study, we analyze the trajectory of one focus-teacher, João (pseudonym), over the four years in which he participated in the PD program, using an in-depth case study methodology. João had a bachelors degree in Biology and 16 years of teaching experience at the beginning of the project. He used to teach science for grades 8 and 9, and during the program (cycle #2) was reassigned as a lab teacher.

Data sources included: audio recordings of interviews (transcribed for analysis), self-assessment reports, and field notes from classroom observation and meeting sessions. Data were analyzed using the Integrated Model of Teacher Professional Growth (Clarke & Hollingsworth, 2002) as a framework for identifying the key elements related to his changing pathways. Although our data analysis process resulted in a series of detailed growth networks describing his changing process, here we present only our main findings.

Findings

Cycle #1

In the beginning of Cycle #1, teachers participated in a 2-day workshop and co-designed a curricular unit with researchers using the backwards design framework. Based on teachers' requests, researchers provided resources and references for the design of the classroom activities aligned with their learning goals. In this initial cycle, João was not expected to introduce constructionist approaches or advanced technology into his classroom, but rather to try out new ways of teaching within his "comfort zone". Before the program, João used the science lab mainly to perform demonstrations of experiments. In his words, “experiments were used for students to see something happening. (...) They just watched me doing it*”.* Students’ roles in these classes were very passive: “they just copied what I put on the blackboard and didn't ask anything”. After participating in the workshop, João mentioned that he started to try out new teaching formats in his lab classes: “My first change was in the way students wrote lab reports. I only asked them two open questions: “what did you learn from the activity?”, and “what were the materials and procedures?”. He also started to incorporate groupwork and more open-ended activities into his classrooms. With this new approach, he saw students more engaged and interested in his classes. However, his perceptions about students’ enjoyment and engagement were the main indicators that the lesson was “good.” As such, in his view, science classes should be more “playful” and “dynamic” as a means to entertain students, which was taken as a direct proxy for learning. In this cycle, he co-designed a unit about genetics, implementing small changes in his teaching, but still mainly relying on traditional, familiar strategies. Since students enjoyed his new way of teaching, he felt confident with these changes to his pedagogical practices.

Cycle #2

In the second co-design cycle, teachers were invited to (1) include science practices as a central part of their units, (2) integrate makerspaces resources for students to engage in deeper inquiry processes, and (3) use formative assessment tools (designed by researchers). For him, experiments and hands-on activities were still seen as the primary way to engage students. However, as he observed students learning in new ways, he was surprised with the results and became interested in collecting and analyzing data about their learning outcomes. Together with the researcher team, João also created a reflection tool to be filled out by him after each classroom implementation.

Cycle #3

In the last cycle, teachers were invited to design, use and analyze formative assessment tools for their lessons. As he said in his last interview, using these tools shifted his evaluation focus to students’ learning processes: “I did not use this type of assessment before - then, what showed me that they learned something was if they knew how to answer a question correctly in the final exam. After we started using these new assessment tools, we were also able to see their performance during the activity, so I started to have a more process-oriented view: the mistakes they make, the questions they ask...”. In this cycle, João designed worksheets for his students and started to video record his classes. After each lesson, he analyzed the worksheets and the video recordings. In a representative utterance during the last cycle, *João stated that the goal of his classes started to be “for them to actually learn”.*

Conclusions and implications

As our findings suggest, at the beginning of the program, João saw *experiments as a way to confirm the theory and to entertain students*, and evaluated his classes based *on the perceived enjoyment and instantaneous engagement* of students. However, as he *incorporated formal assessment tools* to analyze students’ learnings, experiments and “hands-on” activities started to be seen as a *knowledge-building activity*.

One of the implications of our study to the design of PD programs aimed at integrating makerspaces into school curricula is that teachers need *scaffolded and continuous support* to implement changes in their practices: in each co-design cycle, researchers looked carefully at his trajectory to design supporting materials and conduct meetings based on his specific needs. Moreover, special care should be given to the *connections between learning goals and the design of activities*, as well as their *assessment*. In this way, makerspaces’ resources can be used but as a way to engage students in meaningful and authentic learning experiences, and not only to “entertain” them.

Riddle of the Spirit: Cultivating Children's Ecological Imagination through Multiliteracies Pedagogy

Chin-Chin Wong, Kristiina Kumpulainen, Jenny Renlund, Jenny Byman
chin.wong@helsinki.fi, kristiina.kumpulainen@helsinki.fi, jenny.renlund@helsinki.fi, jenny.byman@helsinki.fi
University of Helsinki

Abstract: Drawing on the theory of multiliteracies, this study investigated how a pedagogical design called *Riddle of the Spirit* supported children's (N=62, 7–9 years old) ecological imagination about climate change issues. Preliminary findings showed how the children made sense of the story of an unwell thunderstorm spirit Ukko through multimodal resources and how this supported their ecological imagination.

Introduction

Ecological imagination (EI) refers to the capacity to deliberate and become aware of humans' relations with other lives in the ecological system (Kumpulainen et al., 2021). EI is seen as fundamental to empathy, scientific, affective, sensuous and moral thinking, and creating alternative visions of socio-ecologically just futures (Fesmire, 2010). However, little is known about EI in childhood and how designed learning environments can support the imaginative dimensions of children's ecological thinking. Drawing on *multiliteracies pedagogy* (New London Group, 1996), this study investigated a pedagogical design called *Riddle of the Spirit* (https://blogs.helsinki.fi/echoing-project/riddle-of-the-spirit/) that we have developed. The Riddle design aims to enhance children's EI in deliberating climate change issues and considering humans' relations with nature.

Theoretical frameworks

We investigate the potential for using multiliteracies pedagogy (New London Group, 1996) as an approach to stimulating children's EI. The Riddle design (Wong & Kumpulainen, 2020) offers participatory, analytic, and creative learning opportunities realized via holistic approaches across the arts, humanities, and sciences. Its conceptual basis follows the four core components of multiliteracies pedagogy originally framed by the New London Group (1996): *situated practice*, *overt instruction*, *critical framing,* and *transformed practice*. Altogether, the Riddle design provides seven pedagogical activities through cycles of four steps: Wonder, Find, Think, and Make (see Figure 1). The activities are to be applied inside and outside classroom along with a storyline, playful props, and ongoing discussions guided by teacher facilitation. The project begins with a riddle inspired by Finnish myths about a 'thunderstorm spirit' Ukko losing its climate control as the *metalanguage* and core inquiry (*overt instruction*). With the goal of solving this mystery, children are invited to investigate the reasons for the phenomena drawing on their experiences in the world (*situated practice*). The open-ended activities and collective discussions allow children's critical and analytical reflection on their relations with nature and climate issues (*critical framing*), and to create imaginative solutions around climate problems (*transformed practice*).

Figure 1. The Riddle of the Spirit activities are framed by cycles of four steps: Wonder, Find, Think, and Make.

Methods

Our analysis draws on data collected from an ethnographic study of 62 children (38 boys and 24 girls, 7–9 years old) using the Riddle materials in a primary school located in Finland. During a three-month study period in autumn 2019, research sessions comprising learning activities with the materials were conducted once a week for two hours with the children. In total, 51.4 hours of video recordings of in-class and outdoor interactions along with images of artefacts produced by children and two interviews with teachers are analyzed in this study. Our analysis methods build on visual narrative approaches (Bach, 2008) and are informed by our previous works on investigating relational entanglements of children's ecological imagination (Kumpulainen et al., 2021). Our previous research identified six overlapping intensities in children's ecological imagination: affective, embodied, sensuous, cultural and scientific, symbolic, and moral (see Figure 2). Based on our previous findings of EI, our research procedure began by identifying the six intensities of EI from the video data through thematic analysis. Based on the coding, we identified relevant data sets of children's EI for further analysis and interpretation.

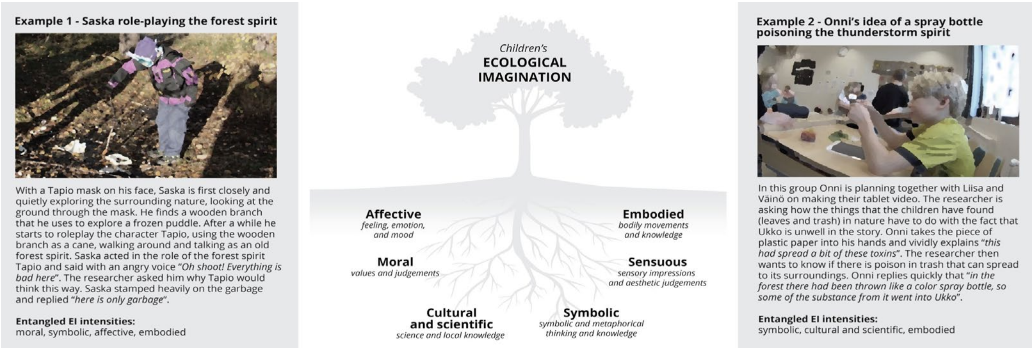

Figure 2. The six intensities of ecological imagination (Kumpulainen et al., 2021) with example 1 (left) and example 2 (right).

Findings and discussion

Our preliminary findings illustrate how the Riddle design supported the imaginative dimensions of children's ecological thinking. Through cycles of meaning-making, the children were found to make intertextual meanings, and to invent new meanings on the relations with the non-human world. In Figure 2, the children expressed new meanings by connecting their sensuous and embodied experiences from the woods and scientific knowledge about climate change with the story of Ukko. Example 1 illustrates how the child Saska's imaginative-moral-embodied-affective experience of 'being an angry forest spirit' was made possible by the activity setup and the multimodal meanings that were constructed into being in the outdoor environment. The role-play mask materially engaged Saska into the imaginative perspective of a forest spirit and Saska responded angrily and critically to garbage in the woods. Moreover, our findings revealed how the Riddle activities allowed the children to creatively and analytically imagine to make sense of the riddle of Ukko. In example 2, replying to the researcher's open-ended question, Onni quickly came up with a story by interpreting a new relation of the spray paint bottle he saw in the woods, his prior knowledge about paint bottles, and the riddle. Onni's narrative manifested his ecological imagination through embodied, symbolic, cultural, and scientific intensities. From the pedagogical perspective, the Riddle design offered the children opportunities to imagine and reflect on humans' relations with nature, as well as to deliberate tensions between the human and non-human worlds. Our results, while preliminary, suggest that the Riddle design potentially supports children's EI by: 1) its mediating material resources that draw upon multiliteracies pedagogy and, 2) fostering holistic and transformative cycles of meaning making.

A Case Study on the Pedagogical Alignment between Science and Makerspace Teachers

César de Castro Brasileiro, Universidade Federal do Ceará, pcpcesar91@gmail.com
Cassia Fernandez, Teachers College, Columbia University, cassia@fablearn.net
Tatiana Hochgreb-Haegele, Teachers College, Columbia University, tatiana@fablearn.net
Paulo Blikstein, Teachers College, Columbia University, pb2755@tc.columbia.edu

Abstract: Using a case study methodology, this paper presents strategies to foster pedagogical alignments between science teachers and makerspace teachers, including ensuring time to plan and reflect on the results together, defining the role of each teacher both in the planning process as in the classroom, and discussing students' learnings to reflect on opportunities for improvement in future implementations.

Introduction

This paper comes from a very particular place of positionality, emancipation, and inclusion. The first author is a POC middle-school teacher in one of the poorest regions of Brazil, who decided to research his own practice, interview peers (the science teacher), and break the traditional roles and boundaries assigned to teachers in Brazil. This work, thus, is an attempt to systematize rich pedagogical practices in a public school, in which the teacher himself is both the researcher and the one implementing the project.

The recent integration of makerspaces in educational environments draws on constructionist theories, which propose that students build their knowledge better while creating and interacting with physical or technological resources (Papert & Harel, 1991). In the context of Brazil, learning in makerspaces is still little explored and lacks implementation strategies suited to the context of public schools, in which one big challenge is teachers' lack of time for planning and preparing materials (Fernandez et al., 2020). As part of a project to reformulate science teaching in a public network in Brazil that includes the implementation of makerspaces, we propose the establishment of the figure of the "makerspace teacher" (here also called lab teacher), as a viable way for makerspace integration. As research shows, in schoolwide reform initiatives, not only time and material resources are needed to promote instructional change but, more importantly, access to the expertise of others (Penuel et al., 2006). Thus, this new full-time teacher has the technical and pedagogical expertise to assist other teachers in planning and implementing curricular units using makerspaces' resources. However, a sustainable model of collaboration between these teachers is not always easy to achieve. Through a case study, this research seeks to discuss which strategies can be deployed to ensure an adequate pedagogical alignment between the lab teacher and science teachers, increasing their ability to integrate making in classrooms.

Methods

Data were collected over three years with a science teacher and a lab teacher (first author) from a public school in Brazil, and include planning and reflection documents upon curricular units, interviews and classroom observations. Curricular units were applied throughout three cycles of implementation and refinement through the design-based research approach (Barab & Squire, 2004), in which researchers and teachers co-designed lesson plans that gradually integrated resources from the makerspaces into science classes and reflected together about points for improvements. Data were transcribed and coded into dimensions of challenges and solutions, to identify and systematize strategies aimed at ensuring greater alignment between teachers in the planning, implementation, and reflection phases of their designed units.

Findings

In the beginning of the collaboration process, there was no adequate alignment between the lab teachers and science teachers, which led to issues during classroom implementations. Based on the results of each implementation cycle, teachers worked to refine their collaboration strategies to ensure greater alignment between them and, consequently, better learning outcomes for the students. Below, we present the main strategies developed by the teachers, divided into three stages: *planning*, *implementation,* and *reflection*.

Stage 1. Planning

In the beginning of the collaboration process, the lab teacher and the science teacher faced a lack of alignment in the implementation of their co-designed unit. In the first cycle, the design of the lesson plan was led by the lab teacher, and the science teacher only validated it with no deep understanding of the strategies adopted. They also did not plan how they would share responsibilities in the classroom - thus, role conflicts arose between them in the classroom, as this science teacher says: *"There were moments in the unit when the roles got confused"*. According to the lab teacher, *"There must be a good alignment before implementation. If that doesn't happen, the unit ends up not being very effective."* To overcome this issue, throughout the subsequent cycles teachers started to hold several meetings before implementing the unit. In our model, around four 50-minute meetings are held between the lab teacher and the science teacher before the implementation of a given unit, organized in six phases: (1) Meeting #1: teachers meet to select the theme of the curricular unit, the number of classes, and the "big ideas" that will guide its development; (2) the lab teacher searches for resources that can be used during classes, related to the big ideas defined in the first phase; (3) Meeting #2: the resources found are presented to the science teacher, and learning goals are also jointly defined; (4) the lab teacher produces materials and toolkits for the unit; (5) Meeting #3, the resources produced are presented to the science teacher, and formative assessment worksheets are produced; (6) Meeting #4: A test run of the unit implementation is conducted.

Stage 2. Implementation
Our data suggest that the roles each teacher plays during the implementation phase must be well defined in advance. One of the strategies adopted to guarantee this alignment is that the science teacher work is more geared towards the pedagogical orchestration and coordination of the class, while the lab teacher, who produced the resources and toolkits, helps students and the teacher with technical knowledge. However, the lab teacher is also free and invited to make pedagogical interventions during the class, as needed.

Stage 3. Reflection
After the implementation of the curricular units, the lab teacher carries out a detailed analysis of the formative assessment worksheets filled out by students and prepares a report that is presented to the science teacher and to the school coordinators. Teachers can then use the results to redesign the unit for future applications.

As a result of the deployment of such strategies, according to the science teacher, the meeting sessions were more productive, there was a greater diversification of the activities implemented in classrooms, and students' participation and learning were improved: *"We can notice this difference during the classes (participation, commitment, attention), and also afterward when we analyze students' worksheets and the level of knowledge that they achieved."* In addition, the science teacher reported that the results shared by the lab teacher helped her to better "*evaluate herself as a professional*".

Conclusions and implications
Our findings indicate that greater alignment between science and lab teachers guarantees better results with optimization of planning time and students' learning. The strategies developed to ensure this alignment include: ensuring joint times for planning and reflecting on the results, defining the role of each teacher when planning and implementing the curricular units, and discussing the results of each unit implementation as a way to improve the outcomes of future implementations. As new makerspaces are being introduced in schools, such strategies can contribute to help teachers to develop sustainable models of collaboration and to refine their classroom practices.

Abstract: Design-based research is uniquely positioned to adapt instructional resources quickly to meet the needs of teachers and students. This paper explores revisions to an educative support that scaffolds (a) scientific argumentation and (b) student task models, in the context of two middle-school science curricula in Chicago. Iterations were informed by: teacher feedback, student work, classroom observations, and teacher and student surveys. Changes supported student task models, NGSS storyline routines, student argumentation, and online instruction.

Introduction

The COVID-19 pandemic has highlighted the ever-present need for research on the design and improvement of educative resources that support teachers and students. In this paper, we share our ongoing design-based research focused on developing an educative support to scaffold student task modeling and scientific argumentation, in the context of NGSS-aligned middle school science curricula. We also discuss how these educative supports were reconceptualized and adapted following the transition to online learning.

Scientific argumentation is a practice that is central to the work of professional scientists and pivotal for the advancement of knowledge in the field. Nevertheless, students often find scientific argumentation to be challenging (Newell et al., 2011; Osborne et al., 2004). One research-based strategy is to explicitly provide students with instruction about the structure of an argument. (Klein et al., 1997). A second research-based strategy is to is to support student notetaking (Greenleaf et al., 2016; Rapanta & Walton, 2016). Drawing from previous research, our educative support, the *Investigation Steps Chart,* helps students track their inquiry activity by asking a set of 5 questions (e.g., How we will use the materials like a scientist to answer investigation question? What have we learned? What do we still need to know?). These monitoring questions incorporate NGSS storyline routines (Reiser, 2017) and are expected to help students develop a task model spanning the entire science unit (Britt et al., 2018). A task model is a learner's representations of the goals (e.g., what do we need to know) and strategies (e.g., how we can use the materials to figure that out) to guide and regulate structuring of the information. The output from this *Investigation Steps Chart* provides the evidence and reasoning that students use for their final argument.

Methods

This design-based research (Cobb et al., 2003) takes place in 7th-grade classrooms in Chicago Public Schools (CPS). It is a collaboration between The Learning Partnership, Northern Illinois University, CPS teachers and the CPS Office of Science. Participants include CPS middle school teachers and their students. Student demographics across schools were: 81% free and reduced lunch, 14% special education, 12% English language learners and 70% African American, 21% Hispanic, 6% White, 0.9% multiracial, 0.6% Asian, and 0.2% Native American/Alaskan. Data sources include: student work, classroom observations, and teacher feedback collected during professional learning workshops. Written parental consent was obtained for all participating students. The educational context of this design work was two different NGSS-aligned curricula. First, Amplify Science, which is the official curriculum adopted by CPS. Second, Journey to El Yunque, a curriculum where students explore and model ecosystem changes in a Puerto Rican rainforest following disturbance events (McGee et al., 2018; McGee & Zimmerman, 2016). Both curricula were structured around units that had a driving question, which students addressed through multiple investigations.

Design and Revision of the Investigation Steps Chart

The *Investigation Steps Chart* consists of a series of questions that students answer before and after the individual science investigations that culminate in a scientific argument. The *Investigation Steps Chart* supports students to develop a task model for each investigation in the science unit, by supporting ongoing and purposeful reflection. Before each investigation, students reflect on: (1) the investigation question, (2) available materials, and (3) how the materials will be used like a scientist. After the investigation, students reflect on: (4) what they have figured out about the investigation question and (5) what they still need to learn. Revisions to the Investigation Steps Chart based on the DBR process included: (a) changing wording to increase emphasis on scientific practices, (b) supporting students to reason about evidence as they collect it, (c) supporting students to collect and organize information about disciplinary core ideas, (d) creating digital versions of the tools, and (e) creating teacher guides for the tools.

Reflection on Engaging in DBR during the Pandemic

As we reflect on our experience engaging in design-based research during a world-changing pandemic, we are struck by the powerfully adaptive nature of the design-based research methodology. Design-based research is inherently oriented towards researchers and practitioners coming together to deepen understanding of learning ecologies, including understanding learning pathways and educative supports, and as such is uniquely positioned to continue seeking solutions, even in the midst of crisis (Cobb et al., 2003). While other types of educational research ground to a halt, our research continued using many of the same techniques as before, adapted to occur digitally instead of face-to-face. As the learning ecology shifted rapidly under our feet, regular conversations with practitioners helped all of us identify obstacles to learning and brainstorm potential solutions. In some ways, the intensity of pandemic conditions had the effect of creating a "window for change" as we began to increase the frequency of our conversations with practitioners and to explore a wider range of potential solutions. In particular, the digital tools we developed during the pandemic will offer a wide range of new possibilities for in-person instruction, as well as online instruction. In other ways, the pandemic slowed our collective endeavor, as technological barriers impeded student participation, student absenteeism skyrocketed, and the pace of science instruction slowed drastically. For better or for worse, this has been a year like no other, and we are committed to carrying its lessons forward as we continue to partner with practitioners to deepen opportunities for student learning. As we continue to test and refine our educative supports, we will build on what we learned by adapting the tools to support remote instruction.

Abstract: This paper uses a case study approach to explore the science teaching identity of Soren, a participant in a multi-year professional development program (PD). We found that shifts in Soren's identity resulted from the combination of *competence* in rethinking science, *recognition* from others, and *performance* of different ways of teaching.

Keywords: science teacher identity, professional development, elementary teachers

Introduction and overview

Science teacher identity, as conceptualized in this poster, is how one sees themselves within the discourses of science teaching, which is contextually situated and ever-changing. Research on science teacher identity has focused on the importance of: (1) past experiences and (2) reflecting on and participating in science teaching and learning (see Avraamidou 2016; Mensah, 2016). Professional development (PD) offers opportunities for teachers to interpret past science experiences and reflect on new ones in considering science teaching and learning through the lenses of new national science standards. However, although the impact of PD on teacher learning has been explored (Simon & Campbell, 2012) the impact of ongoing PD programs on science teacher identity remains largely unexamined. For this study, we bring together two strands of inquiry as we explore the overlaps and (dis)connections among science and teacher identities by asking the question: How does PD support shifting conceptualizations of science and science teacher identity?. We use Carlone and Johnson's (2007) science identity model as an analytical tool. They conceptualize science identity as lying at the intersection of *competence*, *performance*, and *recognition*. They define *competence* as what one knows about science, *performance* as how one engages in science practices, and *recognition* as how others accept that performance. We expand this model by applying it to science teacher identity. Our case study (Stake, 1995) focused on Soren through her year-long participation in a two-year science teaching PD program. Data sources included recordings of the initial summer PD sessions, lesson observations, interviews, and video clubs (school year PD sessions), and artifacts from science unit plans and student work. We concluded our data collection with a timeline interview (Adriansen, 2012). This interview served as a form of member checking and allowed Soren to reflect on her participation throughout the year. To analyze our research question, we drew on Carlone & Johnson's (2007) framework to identify patterns in performance, recognition, and competence related to science, teacher, and science teacher identities. After identifying these areas, we clustered data (Marshall & Rossman, 2014) into categories to identify overlaps, connections, and disconnections. Next, we present our findings, drawing heavily on Soren's own words to illustrate her identity development throughout her participation in the PD.

Findings

Soren is a kindergarten teacher with 14 years of experience at multiple grade levels. During this study, she taught at an elementary school in a large metropolitan area of the southeastern United States. To address our research question about the impact of PD on science teacher identity, we synthesized Soren's reflections on the different aspects of the first year of the program. Soren initially described herself as both a "lover" and "learner" in relation to science. By the end of her first year of participation, Soren was "very comfortable" saying she is a science teacher; however, she questioned whether or not she would consider herself a "master science teacher." This self-identified question connects to the continued growth and changes teachers experience in their various teacher identities.

In reflecting on her experiences, Soren "starred" four areas from PD that she felt contributed most to her identity changes: (1) the summer PD experience, (2) co-planning a unit, (3) teaching the unit, and (4) using the first unit to plan a second one. Soren described connections between teacher and science competence, performance, and recognition, beginning with experiencing science teaching differently as a learner (*competence*—understanding ways of doing science). Soren discussed her initial experience as a science learner in PD as being "mind-blowing" and connected it to the book she was reading, *Making Thinking Visible*, thereby growing Soren’s science teacher competence as she reimagined what science is. From there, Soren shifted to *performance* by engaging in the practices of teaching (co-planning units, teaching and reflecting). As Soren reflected, and put into practice new ideas, she connected her own prior experiences with current PD experiences to inform her future vision for science learning in her classroom. These experiences linked Soren's *competence* to her *performance*. Soren also attributed change to *recognition* from others in the program. For example, Soren noted that a research team member recognized Soren's competence during the co-planning session when "she just could not stop praising what she’d seen and we were on the floor almost surprised that she was so excited about it.” Although unexpected, this recognition supported Soren’s confidence in her new ideas of what it meant to teach science. For Soren, reflection and practice combined with learning in a community allowed her to continually reconceptualize what it means to be a science teacher.

Conclusion

In response to our research question, we found that for Soren, the *recognition* of her science *competence* in PD meetings, opportunities to *perform* a science teaching identity through PD-supported planning and lesson implementation, and PD activities that created space for reflection were central to (re)negotiating her identity. PD supported conceptualizations of science and science teacher identity for Soren through an immersive experience where she experienced science learning differently from her past. As a result, she reconceptualized what science is, while the community provided recognition from others and a space to plan, enact, and reflect on science teaching practices. Soren's story reflects only one teacher's journey. However, we suggest that by supporting teachers in a PD to reimagine science and science education, they may begin to recognize how they were always-already science teachers and imagine new ways and opportunities to becoming-science teachers (Wallace, 2018).

The Use of Narrative in the Development of Spatial Sensemaking Practices

Julia D. Plummer, Kyungjin Cho, Madison Botch
jdp17@psu.edu, kuc64@psu.edu, mab6328@psu.edu
The Pennsylvania State University

Abstract: Limited research has investigated the affordances of programming that promotes spatial sensemaking for children. We analyzed a program which integrates spatially-rich narrative into the design of a museum-based program for preschool-age audiences. Narrative elements from the storybook guided the educator's facilitation of discursive practices which promoted children's spatial sensemaking practices. Children used spatial sensemaking practices to co-construct evidence-based explanations about a spatial phenomenon.

Early aptitude at spatial thinking influences one's opportunities for careers in science (Wai et al., 2009). Fortunately, spatial thinking can be improved through experience and training (Uttal et al., 2013). We investigated how narrative-based science programs support *spatial sensemaking*: cognitive spatial processes manifest through interactions with people and materials (Ramey & Uttal, 2017). Prior research with middle school students has found spatial sensemaking facilitates science and engineering learning (Ramey & Uttal, 2017; Vaishampayan et al., 2019). However, little research has investigated spatial sensemaking for young children. Thus, we ask:

1. In what way can storybook narrative support children's use of spatial sensemaking practices?
2. How does spatial sensemaking facilitate children constructing explanations in science?

We investigated storybooks because stories can be tools to structure and problematize science (Murmann & Avraamidou, 2013) and can generate interest, help us remember, and improve understanding (Norris et al., 2005).

Using conjecture mapping as a design-based approach

We embody our narrative-based program design in a *conjecture map* (Sandoval, 2014), a tool used by learning scientists to represent the relationships between theoretically-supported designs and learning outcomes. Conjecture mapping begins with a high-level conjecture to represent how elements of the learning design lead to desired outcomes (see Figure 1). Over several iterations, we have focused on designs that led to preschool-age children co-constructing evidence-based explanations (Plummer & Cho, 2020; Plummer & Ricketts, 2018).

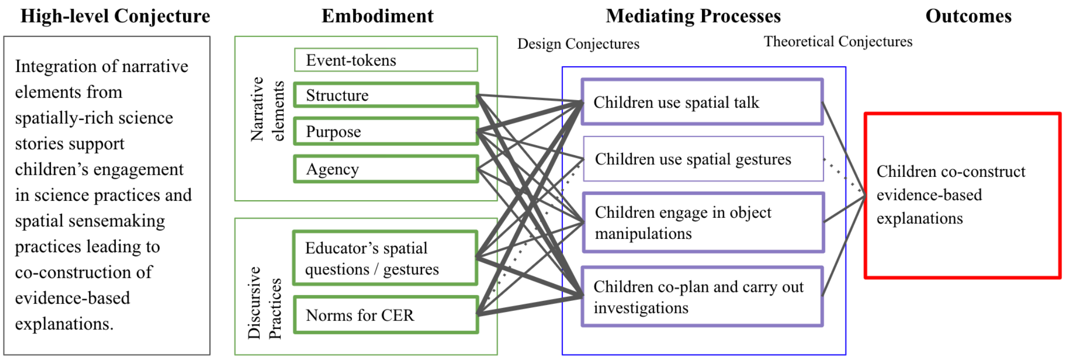

Figure 1. Conjecture map illustrating evidence from analysis of the *Lunar Craters* program.

We conjectured that children's spatial sensemaking practices while carrying out an investigation of a spatially-rich phenomenon would promote their co-construction of evidence-based explanations. Spatial sensemaking practices, particularly spatial talk, gestures, and object manipulation, may be mediators of how children make sense of the spatial nature of science phenomena. We also conjectured that *narrative elements* from the story, introduced through the educator's discursive practices, would prompt the mediating processes of spatial sensemaking and carrying out investigations. These *narrative elements* (see Figure 1), are drawn from Norris et al.'s (2005) theoretical framework for narrative explanations in science (Plummer & Cho, 2020).

Context and methods

We designed a 30-min program to encourage children's use of spatial sensemaking practices. The storybook, *Creating Craters* by Kyungjin Cho, was read by a museum educator ("Anna"). *Creating Craters* is about a brother and sister who go to the Moon, compare the size and depth of craters, and wonder why the craters are different sizes. Anna prompted children to physically explore different sizes of craters, similar to the actions of the characters. Next, children investigated how craters are formed by dropping balls of different masses into a sandbox. Finally, the children made craters using clay to represent their understanding.

We closely analyzed video recordings from one of three iterations implemented at a children's science museum (n=10; average age = 3.9 years, *SD* = 1.22). Using conjecture map elements as codes, multiple authors reviewed the coding to improve validity and reliability. We identified temporal overlap in coded instances which are represented by lines on the conjecture map. The strength of the lines in the conjecture map represents the frequency for which we observed that connection (bold > solid > dotted).

Findings

Findings are drawn from an interpretation of our conjecture map in combination with further interrogation of patterns in coded data revealed by the conjecture map (Figure 1). Program elements (see Embodiment in Figure 1) supported children's use of three spatial sensemaking practices (spatial talk, spatial gestures, and object manipulation), which children used while planning and carrying out investigations to co-construct evidence-based explanations. Our first research question asks how the storybook narrative could be used as a support for children's use of spatial sensemaking practices. Three narrative elements (structure, agency, and purpose) promoted spatial sensemaking practices of spatial talk and object manipulation. The narrative element of purpose also promoted spatial gestures, but less frequently. Further analysis suggests that these narrative elements were embodied in the program design through the discursive practices enacted by the educator: spatial questions & gestures and epistemic norms for evidence-based explanations. Our second research question asks how spatial sensemaking practices facilitate children's engagement in constructing explanations. The most salient conjecture supported by our evidence was that children's use of spatial talk alone or spatial talk plus object manipulation, in conjunction with the investigations they carried out, mediated their co-construction of evidence-based explanations.

Conclusion

Narrative elements from a spatially-rich storybook guided the educator's discursive practices which in turn promoted spatial sensemaking among preschool-age children in the program. Further, children used these spatial sensemaking practices as they carried out investigations to co-construct evidence-based explanations about a spatial phenomenon. In particular, these spatial sensemaking practices were the means by which the children generated evidence and stated their claims as they investigated the spatial phenomenon of crater formation. The use of narrative elements in the program prompted children's spatial sensemaking practices because the educator's questions and prompts drew on the conceptual purpose and engaged the children in similar narrative structures from the storybook. Thus, we recommend selecting science storybooks focused on spatial phenomena for use in planning programs for young children as a mechanism by which educators can engage their spatial sensemaking.

From Novice to Instructor: Inspiring Educators to Facilitate Maker-Centered Learning

Stephanie Yang, Edwin Chng, Bertrand Schneider
szhang@g.harvard.edu, chng_weimingedwin@g.harvard.edu, bertrand_schneider@g.harvard.edu
Harvard University

Abstract: Attaining the benefits of maker-centered learning requires well-trained educators to facilitate complex open-ended projects, a process that begins with teacher education. This study examines how educators experience maker-centered learning, and how they seek to apply these principles to teaching. Ten educator-students were interviewed from a graduate-level makerspace course. Our findings show that educators gained maker skills and a maker mindset along with experiential knowledge, which inspired specific technologies and learning goals for their future students.

Introduction

Makerspaces are environments of learning that encourage students to engage with making through the use of modern digital fabrication tools. Recent interest in makerspaces is fueled by research showing that participation in making encourages engagement with science, technology, engineering, and math (STEM) fields (Vossoughi & Bevan, 2014). Often though, the more salient takeaways from makerspace experiences are not in the form of content-specific knowledge—students come away with skills in collaboration, creativity, problem-solving, and a failure-positive outlook (Clapp et al., 2016; Hsu et al., 2017). Because of this, there is growing advocacy among educators to incorporate aspects of maker principles and activities into K-12 education. Running parallel to these calls is an emphasis on teacher education, since "educators equipped with theory, knowledge, and skills about making are needed to integrate making in formal learning settings" (Hsu, 2017). However, given the nascency of this movement, there is a lack of understanding on how to structure professional development (PD) courses for teachers and the effectiveness of these courses. A national survey on teacher education programs conducted by Cohen (2017) showed the need for an "increase in research on the role of maker principles and technologies in teacher education." While a few emerging studies have researched teacher PD through short-term makerspace workshops (Paganelli et al., 2017) or community-based makerspaces (Jones et al. 2020), there is a lack of research on the effectiveness of a formal makerspace course in shaping future practice and pedagogy for educators. This paper describes an exploratory study of aspiring educators in a semester-long makerspace course situated in a graduate school of education where they learned digital fabrication in the context of educational design.

Methods

The participants of this study were enrolled in a Master's-program level course titled "Making and Digital Fabrication in Education". This semester-long makerspace course had the dual aim of equipping students with the necessary skills to function in a makerspace and also training aspiring educators to become successful facilitators of maker-centered learning in a school-based setting. While the physical classroom was structured like a traditional makerspace equipped with laser cutters, 3D printers, and soldering stations, the course also sought to emulate learning in a school-based setting with more formal and structured learning. The students were trained on how to use the tools through a series of workshops and projects in the first half of the semester and worked collaboratively to design a novel learning tool in the second half of the semester. On a weekly basis, students were also exposed to readings on the makerspace movement, makerspace-related pedagogy, and makerspace research.

The ten interviewees for this study were selected from the eighteen enrollees based on their responses to weekly surveys which captured their self-reported states of learning and emotions. All interviews were conducted by the same member of the research team to ensure the reliability of the results. Questions in the interview protocol were semi-structured and generally categorized into areas that related to the interviewees' background, course experience, course takeaways, and future plans. After several rounds of coding and discussion, the research team derived a common set of codes that would be used to code the transcripts. In total, nine code families were identified with fifty codes created. As a final check on the reliability of the coding process, the researchers reconvened to code the last transcript together and achieved an inter-rater reliability score of 93.2%.

Results

Our findings showed that students acquired both maker skills and a maker mindset, and reflected on how these skills and mindset could be applied in their teaching practice. Another theme throughout the interviews was that students experienced the learning approaches central to makerspaces in new ways and considered incorporating these approaches into their future practice. A sample of the findings is summarized in the table below.

Table 1: Quote-based Findings

Theme	Descriptive Quote	Application to Future Teaching
Maker Skills	"...but without this class, I would not have been doing the electronics stuff, cause I was always kind of scared of working with electricity."	As an example, one prospective history teacher built a dynamic 3D map of evolving landscapes throughout history using the skills he learned in the makerspace. He hoped to share this model with his future students as a teaching tool.
Maker Mindset	"This class was more about learning how to fail. It's the growth mindset thing...and like teaching people to enjoy struggles."	"[my students] never really share their struggles with anybody else...But this mindset from the makerspace is transferable and I want to design a curriculum that can teach them that."
Hands-on learning	"When you're tangibly able to construct something, it just feels a bit more legitimate."	"I'm thankful that I took the course because it's very empowering for me as a teacher to become a designer to think about how you can merge the two worlds...all the tangible stuff. It's very useful in classrooms."
Collaborative learning	"You're always able to achieve more when working with another person than when working independently."	"my experience presented me with a possible way of teaching by building a community"

Discussion and conclusion

The findings showed that students benefited from the structured yet open-ended nature of the class. The formal aspect of the course which incorporated tool demonstrations and scaffolded projects helped make technical activities seem "less intimidating" and more "approachable", particularly for student-teachers from the humanities. At the same time, the informal learning opportunities explicitly built into the course allowed students to experientially study hands-on learning and community-based learning—approaches that they hoped to build into their own teaching. While students experienced benefits of learning in this setting, they expressed interest in more opportunities to consolidate their experiences and brainstorm ways in which they could "incorporate [the takeaways] into [their] own contexts." Some students felt that without the physical environment of the makerspace, they were uncertain about how to "maintain this momentum" for professional applications. Instructors should consider incorporating scaffolded activities that help transition student takeaways and help them maintain these takeaways outside of makerspaces. Overall, these findings provide support for formal makerspace courses geared towards future instructors and provide insights for improvements.

Abstract: Tools that automatically assess and support students are important during remote instruction due to COVID-19 because students do not have direct access to teacher support. We present results of the remote use of virtual labs in an Inquiry Intelligent Tutoring System (Inq-ITS), which captures student performance on practices at the intersection of mathematics and science. Implications are discussed for the development of scaffolding and design of labs to support remote instruction.

Introduction

During the COVID-19 pandemic, teachers faced many challenges with supporting their students' learning in *STEM* classrooms in particular (Reimers & Schleicher, 2020). Specifically, providing support to students remotely requires technologies that can assess students' STEM practice competencies (NGSS, 2013) and difficulties in real time. There are some technologies with this goal for science (i.e., WISE, Vitale et al., 2019) and for mathematics (PAT, Koedinger & Anderson, 1998), but few support the full range of STEM practices. The Inquiry Intelligent Tutoring System (Inq-ITS) is a technology that assesses and supports students on inquiry practices in real time as they complete authentic virtual lab investigations (Gobert et al., 2013). Inq-ITS is currently being expanded to assess and support the practices involved in using math in science (Sao Pedro & Betts, 2019). In this study, we examined data from students who completed Inq-ITS labs with mathematics during remote instruction to address the following research questions: (1) Are math practices more challenging for students relative to other inquiry practices in Inq-ITS?, (2) What influence does the type of math relationship (e.g., inverse square) have on the difficulty of a math practice?, (3) Which specific math sub-practices are most difficult for students?

Methods

Participants in the present study included 4 teachers of eighth grade science courses and their students (N = 74 total students) from middle schools across the United States. Students completed at least one tutorial Inq-ITS lab prior to completing the lab that involved using mathematics in science (i.e., the Gravity and Mass Lab) during remote learning between May to June of 2020. In the Gravity and Mass lab, students use a simulation to investigate how certain variables relate to the force of gravity on a pile of gold on a spaceship. Specifically, students complete three investigations to identify the mathematical relationships between: the amount of gold and force of gravity on the gold (linear), the gold's distance from a planet's center and force of gravity on the gold (inverse square), and the planet's mass and the force of gravity on the gold (linear). Informed by the NGSS (2013) practices, each investigation in the lab consists of six stages: 1) **asking questions**/hypothesizing about the relationship between variables based on a goal; 2) **carrying out an investigation**/collecting data using a simulation; 3) **setting up graphs** by selecting the variables to place on each axis and data to plot; 4) **constructing graphs and equations** by determining the type of mathematical relationship between variables and creating a best fit line/curve; 5) **analyzing and interpreting data** to draw a final conclusion; and 6) **explaining findings** in writing.

To identify the practices that were most challenging for students, we used the validated automated scoring in Inq-ITS (Gobert et al., 2013; Sao Pedro & Betts, 2019) within stages 1–4 (automated scoring for stages 5–6 is in development). Each practice (in bold) is scored according to student performance on sub-practices involved in completing the practices: **asking questions** (identifying the target independent and dependent variable), **carrying out investigations** (running sufficient, controlled trials that target the variables of interest), **setting up graphs** (labeling axes and selecting sufficient data to plot from controlled, targeted trials), and **constructing graphs and equations** (identifying the mathematical relationship in the graph, adjusting the equation to create a best fit curve). The final score for each practice is the average of the sub-practices, scored as binary. We analyzed student performance on practices and sub-practices across the entire lab.

Results

First a Mixed Model ANOVA was conducted to investigate whether there were differences in student performance between teachers and across practices. Results showed that the overall model was significant, $F(3, 68) = 13.46$, $p < .001$, $n^2 = .37$. The between-subjects effect ($F(3, 70) = 1.50$, $p = .223$, $n^2 = .06$) and interaction between teacher and practice was not significant ($F(3, 70) = 1.27$, $p = .290$, $n^2 = .05$), which indicated that there were no significant differences in student performance between teachers. There was, however, a significant within-subjects effect of inquiry practices, $F(1, 70) = 21.44$, $p < .001$, $n^2 = .23$, which means that there were significant differences in student performance on practices. Follow-up analyses using within-subjects t-tests revealed that students performed significantly higher on carrying out investigations ($M = .97$, $SD = .09$) than on asking questions ($M = .92$, $SD = .16$, $t(73) = -2.99$, $p = .004$), students performed well on both asking questions ($M = .92$, $SD = .16$) and setting up graphs ($M = .88$, $SD = .18$, $t(73) = -1.62$, $p = .109$), and students performed significantly higher on setting up graphs ($M = .88$, $SD = .18$) than on constructing graphs/equations ($M = .77$, $SD = .27$, $t(73) = 5.08$, $p < .001$). This suggests that the practice of constructing graphs/equations in science was most difficult for students.

Next, we used a Repeated Measures ANOVA to determine whether there were any differences in student performance on the practice of constructing graphs/equations across the three investigations in the Gravity & Mass lab in relation to the type of mathematical relationship. We found that there was a significant main effect of the investigation, $F(2, 146) = 21.71$, $p < .001$, $n^2 = .23$. Follow-up analyses using within-subjects t-tests revealed that students performed significantly better on the first investigation (linear; $M = .84$, $SD = .33$) relative to the second investigation (inverse square; $M = .61$, $SD = .41$, $t(73) = 5.04$, $p < .001$), and third investigation (linear; $M = .88$, $SD = .28$) relative to the second investigation (inverse square; $M = .61$, $SD = .41$, $t(73) = -5.68$, $p < .001$). There were no significant differences between the first and third investigations (both linear; $t(73) = 1.06$, $p = .292$), but students did perform slightly higher on the third investigation (meaning that students did maintain performance with some improvement from the first to third investigation on this practice). These results support prior findings indicating that students experience challenges with non-linear relationships (De Bock et al., 2017).

Finally, we examined whether there were any significant differences in student performance between the sub-practices involved in constructing graphs/equations using a within-subjects t-test. We found that students performed significantly better on the sub-practice of adjusting an equation to create a best fit line/curve ($M = .83$, $SD = .28$) relative to the sub-practice of identifying the type of mathematical relationship ($M = .73$, $SD = .32$, $t(73) = -3.62$, $p < .001$, $d = .33$). This finding aligns with earlier research findings that students have difficulty determining the type of functional relationships between data (i.e., linear, inverse, etc.; De Bock et al., 2017).

Conclusions and future work

As a result of the fine-grained automated scoring in the Inq-ITS virtual lab, we were able to determine that students had difficulties with the math practice of constructing graphs and equations relative to other inquiry practices, particularly in the context of graphing an inverse square relationship. Additionally, we found that the sub-practice of identifying the type of math relationship in the graph was particularly challenging for students. This level of assessment is critical as we develop auto-scaffolding to ensure students receive support on these difficult practices.

Asking Students to Carry out Generative Learning Activities in Text Learning: Exploring the Role of the Quality of the Performed Learning Activities

Antje Proske, Susanne Narciss
antje.proske@tu-dresden.de, susanne.narciss@tu-dresden.de
TU Dresden, Psychology of Learning and Instruction

Abstract: Tasks such as retrieval practice or self-explaining are expected to trigger generative learning activities necessary for deep understanding. The present study investigated the influence of asking students to either perform re-read, retrieval, or self-explanation activities on text comprehension. Students of two German high schools were randomly assigned to one of three groups when reading expository texts. Subsequently, participants completed a posttest including retention and inference questions. An initial evaluation of the posttest data revealed no significant differences between the groups. This finding raised the question to what extent students actually carried out the requested learning activities and whether the quality of the performed learning activities plays an important role. The results indicate that qualitatively different learning activities are associated to different posttest performance. We conclude that explicitly examining traces of students' learning activities might be a useful supplement in further research on generative learning activities.

Introduction

Learning from a text is an iterative, interactive process in which students process the text information at various levels (e.g., linguistic, text base, situation model level, see for example Kintsch, 1998). The level at which learners process the text information affects how they can later apply it (e.g., reproducing text information verbatim, in terms of paraphrases, or transfer the information to new situations or problems). Deep understanding requires that learners build a situation model by constructing inferences (Kintsch, 1998). Generative learning activities can contribute to deep understanding.

When performing generative learning activities learners infer new knowledge by connecting different information from the learning text and/or by linking this information with prior knowledge (Grabowski, 2004). To elicit generative learning activities, two tasks are very often applied in educational practice and/or examined in empirical research (e.g., Fiorella & Mayer, 2016): retrieval practice and self-explaining. However, research that compares the constraints and outcomes of these two tasks is limited (Roelle & Nückles, 2019). Moreover, research systematically examining not only learners' outcome in terms of comprehension posttest measures, but also if and how the learning activities requested by the task were actually carried out by the learners is almost not existent. The present study compared the effects of different generative tasks in text learning (i.e. re-read, retrieval practice, and self-explaining). Engaging pupils in generative learning activities was expected to foster deep understanding.

Method

The experimental study involved a total of 150 secondary pupils (86 female, *M* age = 15.1 years) at two German high schools. There were no significant differences between the schools for pupils' age and gender.

Data collection was carried out in each school in two sessions (90 and 45 minutes). All materials were provided as booklets. During the first session, all participants read five expository science texts (Hinze, Wiley, & Pellegrino, 2013), and were randomly assigned to one of three groups: The re-read group (n = 51) read each text twice. The retrieval group (n = 54) retrieved after each text the just read information from memory and wrote it in a blank sheet. The self-explanation group (n = 45) self-explained a total of five highlighted target sentences in each text, one paragraph at a time. Three to six days later, students' reading skills and domain-specific prior knowledge were assessed. We included the prior knowledge test at the second session to avoid exposing students to topic-related questions that could influence their learning activities. In addition, the participants completed a posttest on the text information. It contained five multiple-choice retention and five multiple-choice inference questions for each text (50 questions in total, see Hinze et al., 2013).

We assessed the quality of students' generative learning activities by means of a coding scheme. Each student response in the retrieval and self-explanation condition was classified as consisting of either a 1) paraphrase 2) near-bridging inference, 3) far-bridging inference, or 4) knowledge-based inference. In addition, it was examined if a response included a statement on metacognitive monitoring (retrieval group: Krippendorff's Alpha = .75, self-explanation group: Krippendorff's Alpha =.85).

Results

Pupils of the two schools differed with respect to prior knowledge. However, across the randomly assigned groups there were no significant differences for prior knowledge as well as reading skills. Participants of the retrieval group generated more inferences than participants of the self-explanation group. For posttest variables no significant differences between the groups were revealed, either in terms of performance in retention or in inference questions (Table 1).

Table 1: Means and standard deviations of prior knowledge, learning activity and posttest variables (%)

	Re-read group *M* (*SD*)	Retrieval group *M* (*SD*)	Self-explanation group *M* (*SD*)
Prior knowledge	71.18 (15.02)	71.87 (14.45)	73.44 (15.40)
Paraphrases	-	15.67 (8.65)	19.40 (5.06)
Near-bridging inferences	-	7.91 (4.69)	0.87 (1.25)
Far-bridging inferences	-	4.53 (2.77)	2.71 (3.24)
Knowledge-based inferences	-	0.33 (0.64)	1.04 (1.54)
Monitoring statements	-	0.02 (0.14)	21.02 (5.60)
Retention questions post	62.27 (15.16)	63.19 (15.72)	57.24 (17.47)
Inference questions post	59.06 (17.30)	61.19 (19.76)	54.76 (18.43)

Analysis of learning activities in the retrieval and self-explanation groups revealed moderate correlations with both posttest measures for the number of near-bridging, far-bridging, and knowledge-based inferences (r_s between .22* and .36**). In contrast, number of paraphrases and number of monitoring statements were not significantly associated with posttest performance.

Conclusion

The present results indicate that just asking pupils to retrieve or self-explain the text had no benefits for posttest performance compared to a re-read condition. A closer look at pupils' learning activities revealed that students engaged in different kinds of more or less generative learning activities. Some students did so spontaneously, others potentially because the task triggered them to do so. Not all students generated inferences during task completion. Yet, a higher number of inferences was associated with better performance in both posttest measures. It has to be noted that most participants had high prior knowledge, which may have contributed to their engagement in generating inferences (Fiorella & Mayer, 2016; Roelle & Nückles, 2019). Thus, to gain deeper insight into the conditions and effects of providing students with generative tasks, future studies should investigate not only posttest measures but also behavioral traces of students' learning activities.

Making Students' Ideas Visible through Coding a Scientific Computational Model

Tamar Fuhrmann, Teachers College, Columbia University, tf2464@tc.columbia.edu
Cassia Fernandez, Escola Politécnica, Universidade de São Paulo, cassia.fernandez@usp.br
Paulo Blikstein, Teachers College, Columbia University, pb2755@tc.columbia.edu
Roseli de Deus Lopes, Escola Politécnica, Universidade de São Paulo, roseli.lopes@usp.br

Abstract: This study investigates the ideas of 5th-grade students while creating computational models for diffusion. Results illustrate that translating ideas into code can be a strategy to make them explicit. However, there is tension between designing blocks and learning; limited numbers of blocks interfere with students' expressing their ideas, while an open environment can make it hard to converge into acceptable explanations. We argue that creating domain-specific-blocks for modeling needs to be a thoughtfully designed process.

Introduction

Designing computer models is a promising approach to science learning. It combines the advantages of traditional modeling with computational literacy, opening new possibilities for inquiry-based learning (Weintrop et al., 2017; Wilkerson et al., 2015). Nevertheless, developing a computational scientific model can be a demanding task for teachers and students in elementary and middle school. In the past decade, many new environments have been designed to allow kids to create their own models using block-based programming languages and other innovative user interfaces such as NetTango (Horn et al., 2014), Deltatick (Wilkerson et al., 2015), StarLogo Nova (Klopfer et al., 2009). Drawing on these ideas, this paper introduces the designed nine domain-specific blocks of the scientific phenomenon of diffusion as a Scratch extension.

This study aims to explore what ideas students have about diffusion and how they were translated into code during an activity based on the Bifocal Modeling approach (Blikstein, 2016; Fuhrmann et al., 2018). We use the term "ideas" to refer to the understanding that students have developed about the natural phenomena of diffusion of ink in hot and cold water. Students' ideas are challenging to identify, and many times invisible to teachers. In this sense, designing a model with domain-specific blocks can be a valuable way to disclose students' ideas about the scientific phenomenon of diffusion while students are still in the midst of an inquiry activity.

Methods

The study was conducted with seven students in grade 5 through individual Zoom sessions that lasted approximately one hour. The sessions were based on the Bifocal Modeling approach split into four "mini activities" where students created a program to model the process of diffusion after observing an experiment using the designed domain-specific blocks. Data sources included seven hours of video recording and seven computational models.

Results and Discussion

Data illustrates that students had diverse ideas to explain the process of diffusion. Two main types of ideas were observed: ideas that could be tested with the available blocks - for example, the idea of "speed" - and ideas that could not be expressed with blocks - for example, the idea of "melting". A summary of students' ideas is presented in Table 1, alongside quotes that explain their reasoning.

Table 1: Students' ideas regarding diffusion

Category	Description	Sample quotes	Tested with blocks
Number of particles	There are more particles in hot water than in cold water.	*In hot water, I guess there are more particles.*	Yes
Motion	Water particles move more chaotically than ink particles	*In hot water, water molecules are more chaotic than the food color particles*	Yes
Speed	In hot water, particles are faster than in cold water	*They move faster in hot water probably, because you can see that they spread out more.*	Yes
Collision	When particles collide, they change	*When they touch each other, they don't go over*	Yes

	their direction	*each other, they bounce back.*	
Melting	In hot water, ink particles melt	*In hot water, the food color melts. In the cold water, it stays the same*	No
Density	In hot water, bubbles make the particles lighter, cold water is denser	*Hot water particles are maybe lighter. Maybe the bubbles have something to do with it, and the cold it's just denser*	No
Proximity	Hot water particles are separated from each other, in cold water they are closer.	*In hot water, everything separates. (...) The particles are together in cold water.*	No

Conclusion

Our data illustrates that observing students designing a model can be a good strategy to explore their prior ideas and how they evolve over time. Ideas about diffusion that are usually invisible to both the students and the teacher in a traditional lesson become visible, concrete, and sometimes testable using the blocks. When students designed their diffusion models, they needed to understand many details regarding the phenomenon and to "unpack their thinking" since each step revealed a "piece" of students' prior conceptions (diSessa, 2018), which later can evolve to understanding the broader phenomenon of diffusion. However, a key challenge was that some of the students' ideas were not easily representable using the pre-designed blocks. if the goal of engaging students in the coding of scientific modeling is to allow them to explore their ideas, the ways the blocks are designed might interfere with that goal. Even though blocks make coding easier, they also limit some possibilities. As more and more developers and researchers create domain-specific block-based modeling tools, we warn that the smoother learning curve could come at a price: limiting students' explorations that radically diverge from the "official" explanation. Opportunities to implement domain-specific blocks are numerous, and follow-up research is invited to determine more pedagogical affordances and new areas for improvement.

Before the Storm: How Families were Supported for the Transition to Distance Learning

Rose K. Pozos, Caitlin K. Martin, Brigid Barron, Cindy K. Lam, Judy Nguyen, Veronica Lin, Zohar Levy, Susie Garcia
rkpozos@stanford.edu, ckmartin@stanford.edu, barronbj@stanford.edu, cklam@stanford.edu, judynguyen@stanford.edu, vronlin@stanford.edu, zlevy@stanford.edu, susieg@stanford.edu
Stanford University

Abstract: During Covid-19, the amount and quality of preparation for remote instruction has varied greatly across the country. This poster presents findings from a remote diary study that captured a diverse set of families' experiences adapting to remote learning when schools closed in the Spring of 2020. We found that just increasing access to digital resources was not enough; regular, clear, streamlined communication between schools and caregivers was critical to smoothing the transition to distance learning.

Keywords: families, Covid-19, distance learning, diary study, home-school communication

Introduction

The sudden closure of school buildings around the United States due to Covid-19 laid bare the ongoing cost of digital inequities as districts scrambled to finish out the school year remotely. At least 300,000 teachers and fifteen to sixteen million students lack what they need to participate in high quality distance learning (Chandra et al., 2020). These consequential gaps particularly affect lower income, underrepresented minority, and rural families, and must be understood in terms of overlapping, multidimensional sources of inequity in access to learning opportunities (Nasir et al., 2020). How technology is used for teaching and learning has also varied greatly during the pandemic. Pre-pandemic, schools were differentially providing creative and inquiry learning experiences, adding to differences that already occur as a function of family resources (Warschauer & Matuchniak, 2010). Technology in less-affluent schools often features "individualized" progression through workbook-type activities and multiple-choice test practice questions, whereas in affluent schools, technology is frequently used to explore, create, and develop presentations of learning in discussion with peers and teachers (see Darling-Hammond, Zielezinski, & Goldman, 2014). Given the central role of schools in determining access and use of technology, we share preliminary insights into how families were supported by schools to transition to remote learning.

Methods

For two weeks in May 2020 we collected daily documentation from 109 families across the US with children aged 5-10 (grades K-5) using dscout, a smartphone-based remote qualitative research platform (see Barron et al., 2021). Participants were selected from the dscout panel, equally distributed by household income brackets (<$50K, $50-99K, and over $100K). They lived in 28 states, and 55% identified as White, 16% Black, 15% Hispanic/Latinx, 9% Asian, and 4% Middle Eastern/North African. Each selected one child in grades K-5 to focus on in the study (53% were K-2). Caregivers completed 5 mixed methods questionnaires designed to understand the resources and support they received from their child's school before and after the pandemic started, what remote learning looked like for their child, how their family was learning about Covid-19, and the social and emotional impact of the pandemic. We use descriptive quantitative and qualitative grounded theory coding to analyze the responses and gain insights into how families were prepared to handle the transition to distance learning.

Findings

Overall, 44% of participants indicated that they thought they were able to transition well to distance learning, and the results did not differ significantly by income. As displayed in Table 1, the number of digital resources available to families increased after the pandemic. Before the pandemic, higher income families were more likely to report online work required in their child's school (27%) compared to lower income families (5%), suggesting that they may have been better prepared to make the shifts necessary when all learning went remote. After schools closed, higher income families were more likely than lower income families to report having synchronous classes (X^2 = 8.13, p = .017), individualized messages from teachers (X^2 = 8.68, p = .013), and access to teacher-recorded video content (X^2 = 6.78, p = .034).

Table 1: School Provided Supports for Learning Online at Home; Before and During Covid-19 (N=109)

	Before		During	
Reported supports	N	%	N	%
Teacher-led lessons				
Realtime classes or meetings using video	11	10.1%	91	83.5%
Teacher pre-recorded videos of educational content	6	5.5%	64	58.7%
Assignments				
Online assignments (e.g. websites)	36	33.0%	84	77.1%
Ebooks/Audiobooks	16	14.7%	33	30.3%
Pre-recorded videos by teacher	6	5.5%	64	58.7%
YouTube Playlists	13	11.9%	32	29.4%
Paper packets/books	85	78.0%	73	67.0%
Individualized communication				
Individual video or phone check-ins	7	6.4%	53	48.6%
Individualized messages from teachers via email	45	41.3%	87	79.8%
Devices				
Devices to use for learning at home (e.g. iPads, Chromebooks)	53	48.6%	75	68.8%
Hotspots (internet access) to use with devices	25	22.9%	25	22.9%

To understand what preparation made a difference for families, we examined the open-ended text and video responses from contrasting cases. Alma and Cara are mothers of 7 year-old, first grade girls who attend public school. Both mothers involved with their child's schooling before and after the pandemic started, and had markedly different experiences transitioning to distance learning. Through their cases, we see how regular, clear communication between the schools and caregivers was critical for the transition, as were coordinated plans for instruction and sufficient support for caregivers to help their children complete their work. In the poster session, we will go in depth on these cases to illustrate the importance of teacher-caregiver communication and synchronous connections in providing quality remote learning experiences.

Conclusion

Just like a major weather event, the Covid-19 pandemic is forcing families and schools to reckon with their emergency preparations for long-term, traumatic disruptions to student learning. In this poster, we described how understanding the distribution of physical resources is not enough to address equity; the social infrastructure surrounding the resources is critical for a smooth transition between in-person and remote instruction, such as the quality of home-school communication. These results need to be put into the broader context of national conversations about growing inequities, trauma, and an urgent need for reimagining educational environments. The current moment offers challenges and opportunities for growth. As researchers, caregivers, and educators move forward, novel forms of collaboration and interdisciplinary approaches to knowledge creation and design for learning will be needed.

Two Exploratory Case Studies of Teachers' Adaptive Expertise in teaching Bioinformatics in High School Science Classrooms

Jooeun Shim, Susan A. Yoon, Amanda Cottone, Katherine Miller

Abstract: In this study, we use an adaptive expertise lens to examine two contrasting cases of how teachers implemented a data-intensive curriculum in environmental science classes. Analysis showed differing levels of teachers' adaptive expertise as well as challenges when working with data representations. We found that teachers' adaptive expertise depends on teachers' awareness of students' context and extensive knowledge of data literacy and suggest that teacher learning experiences should focus on developing these qualities in instruction.

Introduction

Emphasis has been placed by educational researchers on promoting data literacy in science education (NGSS Lead States, 2013). Initiatives have continued to integrate data literacy into science classrooms through curricula that are embedded in students' contexts, tied to real-world problem solving, and focused on creating artifacts related to community issues using collaborative tools (Kjelvik & Schultheis, 2019). Bioinformatics is an ideal topic for this integration because it is a growing field that incorporates science and big data and has real world needs in the STEM workforce (Tractenberg et al., 2019). However, teaching with bioinformatics content is a complex endeavor (Machluf & Yarden, 2013) and science teachers' content knowledge and skills acquired from professional development (PD) often do not transfer to their instruction and result in a weak increase in student learning (Fischer et al., 2018). Thus, research has suggested that teachers must consider the expertise that is required in instruction, becoming not only technically competent working with data, but also responsive to students' diverse contexts and situations (Almerich et al., 2016). Therefore, teachers' decisions about how to be adaptive in their teaching constitute important information for PD researchers to use to understand how to best support the implementation of bioinformatics. In this study, we use an adaptive expertise lens to explore contrasting cases of how teachers were able to implement bioinformatics curricula in their environmental science classes. This study was guided by the following questions: (1) How is a teacher's adaptive expertise enacted?; and (2) How do teachers use resources to enhance their adaptive expertise?

Conceptual framework

Compared to routine expertise which refers to accomplishing familiar procedural tasks efficiently and accurately, adaptive expertise goes beyond the routine and is defined as being able to use knowledge and skills more flexibly to solve problems in new tasks (Corno, 2008). A study by Authors (2015) used an adaptive expertise lens to evaluate how teachers implemented curricula anchored in agent-based computational tools. They defined adaptive expertise through three characteristics. The first characteristics is *flexibility*, involving teachers' ability to change implementation plans and practices according to emerging issues in the classroom. The second characteristic is *deeper level understanding*, which is the ability to demonstrate a deep understanding of content and pedagogical knowledge as they use that knowledge more effectively to keep students engaged and help them advance to next level of learning. The third characteristic is called *deliberate practices*, a process in which teachers reflect on their instruction to improve teaching performance by first analyzing problems and then trying new approaches.

Method

For this early-stage exploratory case study, we selected two environmental science teachers who taught in two different schools in the Northeastern United States. The first teacher was Clara, who had 5 years of teaching experience and taught 10-11th grade environmental science in a school that was comprised of 99% minority or non-White students, all of whom were eligible for a free or reduced-price lunch. Vera, who had 11 years of teaching experience and taught 11-12th grade environmental science in a school that was comprised of 62% minority students and where 98% of the students were eligible for a free or reduced-price lunch. On the state standardized test, students scored as 26% and 35% as proficient in science respectively. A three-week summer PD workshop was designed to help teachers teach problem-based learning (PBL) curricula that included bioinformatics research, data literacy, and mobile learning. We ran the PD for 75 hours in July 2019. During the PD, the teachers learned the bioinformatics content and introduced to student-centered and community-centered approaches. The curriculum required a focus on solving air pollution problems related to asthma in their local area. Teachers also collaborated to revise and pilot tested curricular content that combined using tools for data collection and analysis tailored specifically to their local student context.

We used a multiple case study method (Yin, 2017) to provide a rich description of our participants' adaptive expertise. The three data sources used were: post-implementation semi-structured interviews; classroom observation notes; and the instructional materials used in each lesson. The semi-structured interview was conducted to probe the teacher's specific practices, beliefs, and understanding of implementing the new curricula, as well as the teacher's experience of preparing the class and participating in the project. The observation notes included descriptions of teachers' instructional practices. Instructional materials included the lesson plans and worksheets. With this data source, we gathered detailed information about the design of and reflection on the classroom activities. Transcriptions of the data sources were analyzed through an iterative mining of the data sources by the authors to identify the instances that would highlight the theme of teachers' adaptive approaches.

Findings

Adaptive Expertise: Flexibility

Overall, Clara demonstrated substantive adaptive expertise. For the *flexibility* category, Clara showed an ability to introduce the bioinformatics projects to students in a way that tied in well with the students' context. For instance, when starting the lesson on asthma, air quality, and bioinformatics, Clara was able to anchor the conversation in current events by using news articles on an explosion at [Blinded city] oil refinery that occurred two months before the class. With this example, she prompted students to think of the complex variables that interact with air quality and their impact on health by asking questions such as "what do you think [the event] did to the air quality for people who lived in that area? How did that affect them? What type of people live in that area?" This example shows that Clara could motivate students with topics that resonated with many of them by using real-world examples that were relevant to students' daily lives. On the other hand, Vera demonstrated less prominent adaptive expertise in her classroom implementation. Regarding *flexibility*, the observation notes showed evidence that she incorporated culturally situated approaches to the project activities, however, there were challenges to her content instruction. For example, one observation showed that she introduced asthma and air quality effectively to students by sharing her personal stories related to asthma and healthcare experiences (09/05/19). Vera was also able to encourage students to answer questions without giving them direct answers. However, when it came to the bioinformatics content, the necessary depth of connections between bioinformatics and the factors contributing to asthma was not evident. The observation notes stated that "there was a lot of info presented and I'm not sure the students really absorbed from just reading definitions on the slide" (09/19/19). This example shows that Vera allowed students to draw upon their own experiences and have discussion about asthma, which captured their interests, but the connection with the bioinformatics was not explicit enough and less situated. More details of findings and further discussions will be available in the larger paper.

Addressing Students' Needs: Development of a Learning Analytics Tool for Academic Path Level Regulation

Eglė Gedrimienė, Anni Silvola, Henna Kokkonen, Satu Tamminen, Hanni Muukkonen

Abstract: Development of learning analytics (LA) tools requires theory-based approach, careful implementation, and user-centred evaluation. In this paper we report on a two-stage user-centred and theory-based development and evaluation of a LA student tool. Results show that LA tool's support for different phases of self-regulation needs to be clearly differentiated and tested with students.

Introduction

Learning analytics (LA) development and implementation lack focus on students as the primary users and grounding in self-regulated learning theory (Tsai, 2020). Design and use of LA tools require careful consideration as LA has been shown to have both positive and negative impact, in some cases diminishing students' motivation and goal orientation (Lonn, et al., 2015) which is argued to be in connection with atheoretical approaches and low participation of users in the design of LA tools (Matcha, 2019).

To develop the LA tool for students we took a user-centred, theoretically grounded approach combining expertise of the multidisciplinary team. We grounded the development and evaluation of the LA tool in theory of self-regulated learning, which is described as consisting of four phases: Planning, monitoring, controlling and reflection (Pintrich, 2005). The aim was to create scientifically grounded, student-centred LA tool supporting self-regulated learning on the level of academic paths, referring to study periods and academic years. This is a novel approach in comparison to previous studies emphasizing LA use in course level. We present the development process, developed visualizations (Fig.1 and Fig.2), and students' feedback.

First, student needs were identified through recorded small-group conversations focusing on higher education academic paths and LA. Addressing self-regulation skills, students' needs for continuous overview of their progress and development on the academic path level and support for time management were the most prominent themes (Silvola et al., 2021). The first LA tool version, consisting of two visualizations, was developed, and tested in the context of academic advising conversations. The visualizations described student progression based on their personal study plans and student success within courses included in the plan. Student experiences showed that the LA tool made students' support needs more explicit and was especially useful for students experiencing difficulties in their studies (Hooli, 2020). The design and implementation of the LA tool was carried out by educational psychology and IT specialists and utilizing legal experts to identify and prevent possible data privacy risks. The second LA student tool version was developed with additional visualization aimed to support self-regulation. As visualizations of grades in the first version of the LA student tool resulted in mixed student experiences (Hooli, 2020), two new visualizations were added to give an overview of the progression on the academic path level, two on planned courses and credit distribution through time (two visualizations in the left upper corner), and one on distribution of attended courses across study fields.

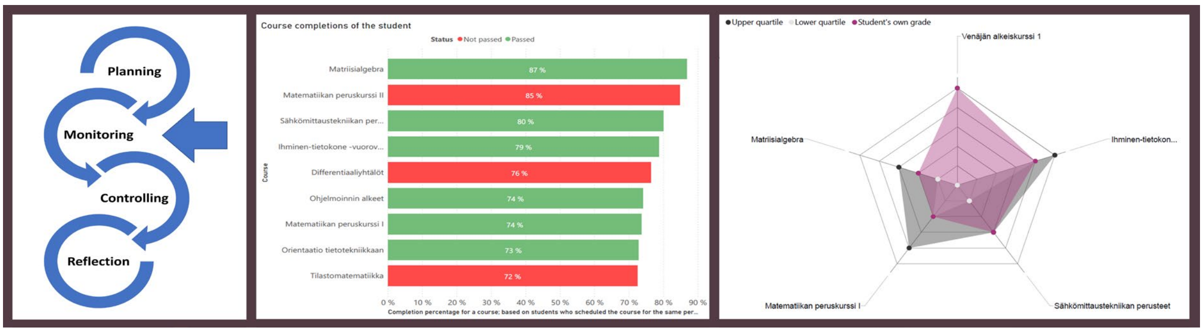

Figure 1. Visualizations in the first version of the LA student tool supporting phases of self-regulated learning.

Results and discussion

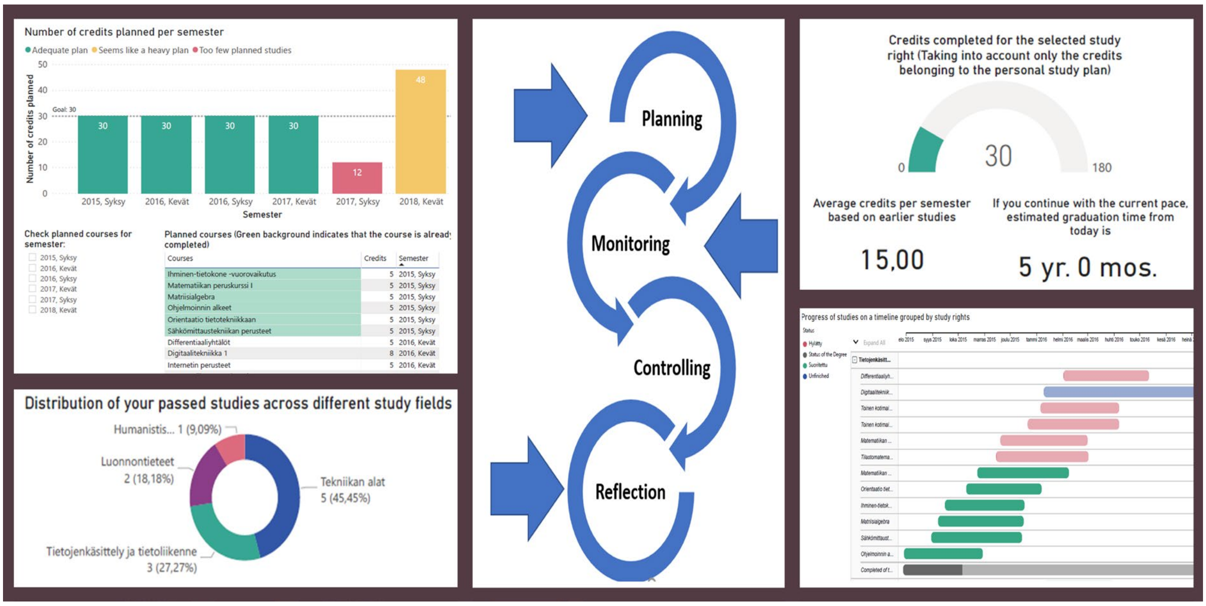

Figure 2. Visualizations in the second version of the LA student tool supporting phases of self-regulated learning.

Preliminary results indicated that students evaluated information about study plans (courses and credit distribution through time) and study progress (completed and not completed courses) as the most useful. Estimated graduation time and own grades were also evaluated positively. Comparative information (grades and course completion percentages of other students) remained controversial. Second version of the tool worked well to support students' study planning (goal setting and creation/revision of the study plan) and monitoring. On the other hand, the tool was less helpful for reflecting over the study behaviours and results or improving study habits.

This study showcases the ongoing research and implementation of theory driven, user-centred LA student tools in a higher education institution. Results show, that created LA tools must be carefully tested to understand if they serve their prescribed aims from the students' perspective. Further research is needed to better understand how the final version of the tool supports phases of self-regulated learning on the academic path level and what functionalities are useful for different students in comparison with regularly used tools.

Abstract: At two professional developments (PDs), we position teachers as curriculum co-designers to support the integration of computing into traditional K-12 classrooms. Four case studies of teachers' successes and challenges over a four-week period showed that each teacher required differentiated support to address personal fears and concerns. Results suggest flexibility and team discussions may particularly support teachers in co-design and enhance future PDs focused on developing computational activities for students in the K-12 classroom.

Introduction

Much work advocates for integrating computational activities in traditional K-12 classrooms because such activities can provide students with authentic learning experiences, deepen learning of content, and increase equity in a future increasingly dependent on computing (Grover & Pea, 2013; Weintrop, et al., 2016). However, the integration of computational activities requires substantial support for teachers to adequately learn new skills and technologies (Kali, McKenney, & Sagy, 2015). Recent work addresses this issue by engaging teachers in collaboratively designing computational activities alongside researchers as a means of increasing teacher ownership and technological pedagogical content knowledge (Cober et al., 2015). Co-design positions teachers as subject matter experts, involves them in writing underlying code, and allows them to eventually build computational activities themselves. Given the diversity of co-design, more work is needed to understand how to support teachers as individuals while progressing towards a common goal (Chval et al., 2008; Kali et al., 2015). To this end, we investigate teacher experiences at two different summer institutes that provided PD through engaging teachers in collaborative design of computational activities with researchers. We examine teachers' challenges and successes as they co-designed computational activities over the four-week PDs.

Method

Two universities each conducted a four-week summer institute that positioned teachers as co-designers of computational activities for their students. University 1 paired 11 high school teachers from a large US Midwest city with researchers to co-design computational thinking (CT) activities in PD henceforth referred to as CTSI (CT Summer Institute). University 2 engaged three middle school teachers from the Intermountain West to co-design theory-building (TB) activities with one PI and four graduate students in PD henceforth referred to as TBSI (TB Summer Institute). Both PDs introduced computational activities and tools in the first week by asking teachers to explore models in existing CT or TB units and discuss how the activities in the units supported student engagement. The latter three weeks focused on co-design of new CT or TB units.

At CTSI, teachers worked on their units in small co-design teams by subject area with at least one CT researcher and undergraduate assistant. All 11 CTSI teachers met weekly for CT workshops and feedback sessions. We analyzed teacher responses on a Google Forms survey collected during a Weekly Reflection held on Fridays: "What went well for you or your work this week?" and "What was a challenge for you this week?"

At TBSI, the teachers and researchers met every morning for Scrum team-building sessions, and every Friday afternoon for a Weekly Reflection meeting. During both meetings, teachers responded to the questions: "What did you enjoy?" "What did you find challenging?" "What did you learn?" "What goals do you have?" "Do you have any feedback for improvement?" Meeting discussions were recorded, transcribed, and analyzed.

We identified teachers who developed computational activities each week and completed a unit by the end of the four-week PDs as well as teachers who struggled in one or more weeks in the co-design process.

Results

We highlight one teacher from each summer institute who was "successful" (Brooke and Mary, pseudonyms) or "struggled" (Evan and Rebecca) at our PDs. In Week 1, Brooke from CTSI and Mary from TBSI both felt "excited" about computational activities and integrating them into their classes. Yet, they both struggled in Week 2 when planning their unit. Brooke decided to reverse the sequence of her class activities, which took time. Mary originally felt she had to "know all of the things to make a simulation." Once her co-designer had built her model, her vision shifted to focus on the big ideas: "to build these models means you have to think of all the parameters and all the things that are interacting which can lead to some really big ideas and understanding." By Week 4, Mary was back to feeling "excited about the things I want [students] to pull out when the students do the model." Brooke took on building her own computational models with support from co-designers, making her "really proud of the unit coming together and of how collaborative it was" (Week 4).

In contrast, Evan (CTSI) and Rebecca (TBSI) faced various challenges when developing computational activities during the four-week PD. For Evan, his challenge in Week 2 was "[s]taying focused on working on [his] unit, really beginning to think what [he] want[s] the kids to get out of it." After more regular discussions with his co-design team, he started working on activities in Week 3, noting: "this unit is NOT going to be perfectly polished, finished by next Friday." By Week 4, he was "[w]orking with [his] co-design team to finalize most of [his] unit" which was completed in the fall. Early in Week 1, Rebecca expressed concerns with coding ("What have I gotten myself into? I'm diving in very scared because I don't code."), theory building ("This is the first time I have conceptualized what theory building means in the classroom. I have always thought that theory building is something someone else does and my job is to bring students to understand those theories."), and unfamiliar tools. She started developing activities, but by Week 4, she still did not have an understanding of her computational activities until a researcher developed a graphic novel ebook, which used a storytelling analogy to explain the process of building a computational model. Rebecca stated: "The ebook to explain coding is really good and I think it is helping me a ton! I was able to understand more about what is not right with my own blocks. I went back to the first model and felt way more confident." Her unit was completed shortly after the institute.

Discussion

Results showed that our teachers were able to ultimately integrate computational activities (and even design their own computational models!) through co-design. However, their progress drastically differed due to various challenges, including confusion about computing (Rebecca), staying focused (Evan), and concern over building computational models (Mary). Some teachers, such as Rebecca, face multiple obstacles that require additional resources and support. Such divergence in teacher progress and outcomes align with findings from prior research on co-design PDs, which showed diversity in teacher pathways (Naimipour et al., in press).

Co-design allowed us to address the different needs of teachers through individual adjustments and just-in-time resources during our PDs. Because K-12 teachers are often not trained in computational skills and may face fears about computing, we must address their individual needs, knowledge, skills and beliefs as learners and designers. With such qualitative understanding of individual needs and ways to support them, we can further develop PDs that center on building close relationships with teacher partners and address their challenges through co-design so that they can engage with and integrate computational activities in the K-12 classroom successfully.

Improving Teacher Noticing of Students' Science Ideas with a Dashboard

Kelly Billings, Libby Gerard, Marcia C. Linn
kelly_billings@berkeley.edu, libbygerard@berkeley.edu, mclinn@berkeley.edu
Graduate School of Education, University of California, Berkeley

Abstract: We explore how a Teacher Action Planner (TAP) that synthesizes student ideas impacts teacher noticing. The TAP uses Natural Language Processing (NLP) to detect student ideas in written explanations. We compared teacher noticing while using the TAP to noticing when reviewing student explanations. The TAP helped teachers deepen their analysis of student ideas. We did not see any impact on immediate instructional practice. We propose redesigns to the TAP to better connect noticing to instruction.

Keywords: teacher noticing, natural language processing, NGSS, Knowledge Integration.

Introduction

Created in partnership with the Educational Testing Service, the Teacher Action Planner (TAP) uses Natural Language Processing (NLP) to summarize student ideas about science concepts. This summary and the recommended actions based on the student ideas are informed by Knowledge Integration and the NGSS. The TAP was implemented in the WISE Plate Tectonics unit for the first time to support teachers in reflecting on student ideas and planning their instruction (Zhai et al., 2020). This study focuses on investigating how the TAP supports teacher noticing of student's science ideas, as well as how recommendation actions might support teacher planning for distance learning.

The *Knowledge Integration Framework* outlines four processes that support students in developing scientific ideas. They include eliciting initial ideas, discovering new ideas, distinguishing between ideas, and revising their original perspective (Linn & Eylon, 2011). In this study, the TAP pretest report summarizes what ideas students are initially *articulating* at the beginning of the unit, which teachers can use to support their planning. The posttest report summarizes how students *revised* their initial ideas based on what they have learned from the unit and can help teachers to reflect on their teaching and student learning.

Methods

A TAP report was created for the item called Mt. Hood, which calls for students to link ideas about plate interactions and convection currents. We created rubrics to assess each student's explanation along three dimensions: *Knowledge Integration*, the DCI *ESS2.A Earth's Materials and Systems,* and the CCC *Energy and Matter* (Gerard et al, 2020). An NLP model was developed to automatically score student explanations the Mt. Hood Item (Riordan et al, 2020). The resulting model scored student responses with accuracy comparable to human-scorers (quadratic weighted kappa KI=.861, CCC= 0.836, DCI=0.763) and was then embedded into the Mt. Hood item to create a TAP. 'Recommended Actions' in the TAP were designed to help teachers use the summary of Mt. Hood scores to plan instruction and were based on an initial meeting with the lead teacher at the participating school.

We used a cross-case comparison study to examine how teachers used the dashboard. Four 7th grade teachers and their 504 students participated in this study. Two of the 4 teachers had access to TAP reports (Teachers 1 and 2) and two teachers had access to only logged student explanations (Teachers 3 and 4). This was the students' first unit of distance learning for Fall 2020. Teachers used a combination of WISE, Google slides, and Zoom.

Student data included student explanations on the Mt. Hood pre/post item. Each teacher was interviewed twice, after the pretest and again after the posttest. Interviews were analyzed using an emergent coding approach to find themes in teacher's noticing of student thinking, plans to adapt instruction, and their feedback on TAP design. Researchers observed synchronous Zoom classes to see how the teachers used the TAP or student explanations to adapt their instruction. Observation data was examined to discern similarities or differences between the teachers.

Results

The pretest interviews suggest that teachers in the TAP condition noticed more details about their students' ideas than those without the TAP. Teacher 1 noticed that students scored low on both NGSS standards. They wanted to look at the data in more detail, saying "*it would be nice if [the TAP] can figure out student misconceptions or incorrect ideas.*" They wanted more targeted information about individual students to identify which students to assist. Teacher 2 noticed differences in student ideas between their class periods. They noticed that one of their class periods scored low on both NGSS standards and remarked, "*This surprises me, because they talked about it last year.*" They also noticed that the majority of students in this same period were struggling "*in that integrating piece.*" In contrast, their other periods displayed a stronger understanding. Both teachers noted that the TAP's recommended actions affirmed their original plans. Teacher 2 said "*[The TAP] gives me a little bit of confidence to do what I was planning to do.*" Teachers without the TAP did not have these insights from examining the student explanations and did not dive deeply into student ideas during their interviews. For instruction, the teachers followed a similar, agreed-upon plan to implement the unit. The alignment among teachers and with their original plan meant there were few opportunities to adapt instruction.

During the post-interview Teacher 1 identified a key idea that their students had trouble with. Students "*were confused about heat transfer and density*" as it applied to convection currents. The teacher elaborated, "*[Students] moved from level 1 to 2 and 3 in DCI. In CCC they mostly just moved to 2 and not a lot of them moved to 3*." The teacher's observation was reflected in the average student scores in the posttest across all classrooms. Teacher 1 wanted to explore this data more closely by looking at individual student data but was unable to due to the current limitations of the TAP. They suggested this as an important area of improvement. Teacher 2 noted their students' growth from pretest to posttest. "*I see a lot more 2s and 3s as opposed to when we first started*." They again noticed the difference in student understanding between periods. "*It's clear my period B is struggling. They may need a little more structure and a lot more discussion time.*" They found this helpful for planning how they can support their different periods in the future. Teachers 3 and 4 did not mention either of these observations when they looked at their posttest student data. Teacher 3 mentioned that they would take a closer look at the data later when they input grades. Teacher 4 said they noticed an improvement but did not look into student explanations in detail.

Conclusions and implications

While previous studies with the TAP focus on teacher implementation of recommended actions (King Chen, 2020), this study brings to light key insights about how teachers use the dashboard to analyze student data. Teachers who had the TAP were able to deepen their understanding of ideas students were still missing and were able to identify differences in performance between class periods. Though informative, the recommended actions provided by the TAP did not prompt teachers to change their instruction. The next steps for refining the dashboard include adding more specific data on individual student NGSS aligned scores to deepen teacher noticing and more closely aligning recommended actions with the student data to help teachers deepen their analysis of specific student's data.

Collaboration and Peer Social Relationships: The Role of Friendships in Middle School Inquiry Science

Karlyn R. Adams-Wiggins, Cameron M. Haluska
Portland State University, PO Box 751, Portland, OR, USA 97207
karlyn@pdx.edu, cameronhaluska@gmail.com

Abstract: Early adolescent learners in inquiry-based science learning environments must grapple with regulating group activity as well as the socioemotional challenges of collaboration. The current study early adolescents' understandings of the role of peer social relationships and friendships in collaboration in middle school inquiry classrooms. We qualitatively analyzed end-of-semester interviews with 32 seventh grade students who participated in a semester-long series of inquiry units. Results suggest that early adolescents view peer relationships and friendships primarily as beneficial resources to support self-regulated learning and minimize the impact of competence and peer group concerns on learning, while friends were seen as particularly helpful for smoothing group interactions and promoting cohesion. Further, early adolescents distinguished between types of friends, with a focus on friends who would support group functioning. Specific to argumentation and explanation as scientific practices, early adolescents viewed peers as an important source of alternative perspectives and explanations.

Introduction

Reform-oriented science curricula leverage collaboration as an avenue for rich opportunities to learn through productive disciplinary engagement and inquiry. Yet, learners can struggle to effectively regulate group activity in addition to struggling with scientific practices like argumentation and explanation (Berland & Lee, 2012; Kuhn, 2020). Developmental science research has addressed the central role of peer social relationships and friendships during adolescence. This literature distinguishes between peer relationships generally and friendships specifically: friendships are positive, strong bonds between people and friends use their relationship to achieve socioemotional goals. Peer relationships and friendships both are also related to self-processes, as information from these relationships informs academic self-concept and self-esteem through social comparisons and self-evaluations (Bukowski & Raufelder, 2016). Further, research on status problems in the classroom has highlighted how early adolescents rely on peer status orders, or popularity-based hierarchies, which operate alongside academic status orders at the middle school level (Lloyd & Cohen, 1999). Finally, some findings suggest benefits to working with friends over acquaintances for problem-solving accuracy on difficult variable isolation problems (Azmitia & Montgomery, 1993). In sum, mitigating challenges to high-quality collaboration in inquiry-based science classrooms likely will require attention to peer social relationships and friendships. The present study examined the following question: how do early adolescent learners understand the role of existing peer relationships and friendships in collaboration in inquiry-based science?

Method

Participants came from four 7th science grade teachers' classrooms participating in inquiry-based science curricular units over the course of a semester. Curriculum units focused on life science topics such as genetics, evolution, and cells. The units were designed to promote reasoning and argumentation; lessons were collaboration-intensive. Data for the present study were collected from transcribed semi-structured interviews with the 32 student interviewees. Mean interview length was 18 minutes, with some interviews lasting as long as 30 minutes. Students were asked about their perceptions of group processes and inclusivity of interactions within groups. Two interview prompts were identified as relevant to the present research question: 1) "In what ways, if any, do you benefit from learning with your classmates in a group in science class?" (Follow-up: "What have you learned that you might not have learned if you had worked independently?") and 2) "Do friendships contribute to how well the group works together?". The authors developed a coding scheme using 10% of the sample and coded the remaining interviews. Frequencies were calculated for the number of students receiving each code.

Results

Frequencies for the themes identified can be seen in Tables 1. Among all of the themes discussed by students, themes referring to pre-existing peer relationships and friendships as beneficial were typical. A theme that did not reflect a clear benefit or disadvantage of pre-existing peer relationships and friendships was Effortful and Useful Contributions Overriding Role of Friendship (22%).

Table 1: Advantages and Disadvantages of Peers & Friends – Frequencies

Theme	Frequency	Percentage
Exchange of Ideas & Alternative Perspectives from Others	25	78%
Content Knowledge Development & Self-Explanation	14	44%
Social Skill Development & Perspective Taking	12	38%
Group Cohesion	11	34%
Help Receiving	10	31%
Task Distraction	7	22%
Social Anxieties - Peer Group Concerns & Shyness	5	16%
Risk of Exclusion/Unfair Consideration of Ideas	5	16%
Social Anxieties Competence Concerns	2	6%
Too Few Perspectives/Skill Sets	1	3%

Interview excerpts indicated differences in the role of friends versus peers. Peers were seen as valuable resources for learning through the exchange of ideas and receiving explanations, providing support for self-regulated learning processes, and offering opportunities to learn from mistakes. Learning with peers raised concerns about appearing competent and fitting in, but collaboration itself somewhat alleviated those concerns. Friends' presence reduced the burden of managing social interactions during collaboration, partially by alleviating social anxieties and counteracting shyness. Students noted the value of friends for ensuring one's ideas are heard during collaboration.

Discussion and conclusion

Taken together, the results presented here indicate that early adolescent learners view peers as promoting sufficient consideration of counterarguments, supporting self-regulated learning processes such as monitoring, and providing opportunities to learn from mistakes. Further, they see friends in particular as offering socioemotional protections that enhance motivation. Learners valued friends who would make good collaborators; and recognized the importance of friends for helping reduce the negative impact of academic status hierarchies. Further, Exchange of Ideas & Alternative Perspectives from Others was the most referenced benefit of collaboration, with over 75% of students discussing it. Science education researchers note important distinctions between arguments and explanations (Berland & McNeill, 2012; Osborne & Patterson, 2011), but the adolescents in the present study spoke in somewhat generic ways about what exactly was being exchanged. Future research should aim to clarify what observed discursive moves are reflected in learners' conceptualizations of "sharing ideas". Interventions to promote adaptive outcomes considering learners' motivational concerns should aim to preserve beneficial classroom social practices like collaborative argumentation.

Curricular Mechanics for Motivation

Taylor Kessner, Arizona State University, tkessner@asu.edu
Caitlin Hayward, University of Michigan, cholma@umich.edu

Abstract: We propose *curricular mechanics for motivation* as a mechanism by which educators might counteract curriculum violence perpetrated on students at the level of curricular design. We ground our discussion of these curricular mechanics in gameful learning principles and self-determination theory (SDT) (Deci & Ryan, 2002). We outline six examples of such mechanics, drawn from syllabi from courses taught at a large public R1 university.

Introduction

Curriculum violence, when enacted curriculum compromises learners' intellectual or psychological well-being (Ighodaro & Wiggan, 2010), remains under-attended to at the level of curricular design. Curricula are often designed with (well-intended) coercion in mind: how can we get students to comply with our expectations for how they should learn and demonstrate both effort and progress? We contend this violence is often perpetrated along racial and socioeconomic lines in schools typically denied adequate funding and adequately prepared faculty through systemically unjust institutions. One framework for confronting this problem is gameful pedagogy, which proposes that by creating space for learners to have agency within the classroom and designing curricula to support student motivation, we can collectively begin to address the historical structures that have led to curriculum violence. We introduce *curricular mechanics for motivation* as a theoretical framework and design mechanism for attending to these concerns.

Games-inspired learning

Interest in games for learning has remained high across the last two decades among scholars and practitioners. A popular misconception of Gee's (2003) seminal work in the field, however, is that games are the only context in which the principles of engagement he outlined are applicable. This misconception has led to a proliferation of games designed for classroom use, while the empirical evidence for their effectiveness remains mixed (Gee, 2011). *Gameful learning* (Hayward & Fishman, 2020), in contrast, takes up Gee's fundamental proposition: that good games are designed with powerful learning principles at their heart, and that these principles could be applied more to learning environments of all sorts outside of games. We build on this work here by discussing gameful learning design in greater detail through the lens of game mechanics.

Curricular mechanics (for motivation)

Our conception of curricular mechanics relies on a framing of school itself as a game–albeit a poorly designed one. Simply put, game mechanics are the ways players take action within the game world to pursue goals. Players see and make sense of the game world in terms of verbs, or what they can do as part of gameplay (Gee, 2015). *Curricular mechanics*, then, are mechanisms by which learners can take action within the curriculum. Traditional curricular designs typically constrain learners' choices: go to class, or do not; complete and turn in assignments, or do not; study for the midterm and final, or do not. Gameful pedagogy contends that designing more curricular agency for students increases intrinsic motivation, yielding a variety of positive outcomes from increased learning, reduced academic anxiety, more creative work, and more collaborative engagement (Hayward & Fishman, 2020).

When describing curricular mechanics for motivation, we mean the pedagogical structures by which learners are given control to select both their learning goals and the pathways they will travel in pursuit of those goals. For the purposes of this proposal we focus on curricular mechanics through the lens of SDT, which highlights three pillars essential to experiencing intrinsic motivation: autonomy, belongingness, and competence.

Examples of curricular mechanics for motivation

Table 1 outlines six example curricular mechanics designed into undergraduate course syllabi at a large American public R1 university, including the gameful learning principles grounded in SDT they embody.

Table 1: Example curricular mechanics

	Description/Example	Autonomy	Belongingness	Compe tence
Difficulty levels	Assignments descriptions include information about what knowledge is necessary to be successful, and recommendations for alternative assignments are available if students would like to learn/practice necessary skills in advance.	X		X
Multiple paths to success	Students start with zero points and build up, and more points/assignments are available than needed for full credit, meaning poor performance at any point along one pathway does not close other pathways to success.	X		X
Assessment choice	Students are empowered to decide what medium (e.g., essay, blog, vlog, creative effort) they wish to use to show mastery.	X		X
Team competitions	Students are placed in teams, and at strategic points throughout the curriculum these teams compete together in topical challenges.		X	X
Clear and forgiving late work policy	Instructor designs a clear policy on late work that includes latitude, encouraging students to make choices that privilege their own socioemotional health, which communicates that they are valued as a human.	X	X	X
Assessment weighting	Students choose to what degree (%) specific assignments will count towards their grade. This lowers consequences for failure, encouraging risk-taking.	X		X

Discussion

We view the work we have herein in two ways: (a) as a design framework, and (b) an analytic framework. First, we contend curricular mechanics for motivation specifically is a useful tool to aid educators as they design course mechanisms with their learners' humanity front of mind. Second, we envision future work in which curricular mechanics may be leveraged as a broader analytic lens for making sense of the interplay between curricular designs and learners, with interaction forming the catalyst between them.

Expanding How We Record and Report Learning: Exploring Employers' Perspectives

Steven Cederquist, Barry Fishman
cedsteve@umich.edu, fishman@umich.edu
University of Michigan

Abstract: This paper presents employers' perspectives on how they make sense of students' cognitive, non-cognitive, and technical ability utilizing data from resumes, academic transcripts, and various interview techniques. Employers' perspectives on a skill-based transcript as a tool for hiring are also reported. The findings inform the design of future assessment and credentialing infrastructures, with the goal of expanding how knowledge and ability are measured and defined in higher education.

Introduction and theoretical framework

This paper reports on the first study within a larger effort to reshape undergraduate education in a U.S. research university around twenty-first century learning outcomes and problem solving, instead of traditional course sequences. The purpose of the study reported here is to understand the broader implications of this larger effort as it relates to the recruitment and hiring practices of companies likely to employ graduates of the proposed program. A key feature of this program is a shift from summative information such as letter grades and grade point averages (GPAs) to mastery-based assessment for learning. This summative information makes up the underlying and often-unquestioned infrastructure of what is considered "normative" in education (Star & Ruhleder, 1996). Additionally, research on skill assessment finds "potentially important non-academic skills" are not well understood through summative information (Stasz, 2001, p. 393) and research on hiring suggests summative information contributes to subjective evaluations of ability through processes of cultural matching (e.g., Rivera, 2012). How would shifting to mastery-based reporting of knowledge and ability affect the ways that companies identify and select potential employees from among college graduates? To address this question we interviewed recruiters and hiring managers (hirers) to understand how they currently make sense of the information they have about students and sought their perspectives on the challenges and opportunities of implementing a mastery-based learner record as an information tool for recruitment and hiring. By exploring new infrastructures for communicating about knowledge and ability, we hope to understand designs for assessment infrastructures that are better able to account for twenty-first century learning outcomes rather than "master narratives" of school success (Penuel, 2019).

Methods

We recruited twelve participants from organizations that employ graduates of an existing pre-professional bachelor's degree program in a U.S. research university. Participants were selected to represent a broad range of organizational types and represented consulting, financial services, manufacturing, and consumer goods and services companies. Recruitment, interviews, and analyses were conducted iteratively, and recruitment proceeded until it was felt that no new information was being gained.

Interviews were conducted via videoconference, lasting roughly one hour. Topics focused on: (1) The participant's position within their organization, (2) The stages of the hiring process in their organization, (3) The factors shaping their approach to recruitment and hiring, and (4) The specific information sought at each hiring stage. At the end of each interview, participants were presented with an example of a comprehensive learner record (CLR) and asked for their reaction and thoughts about what role(s) it could play in their hiring process. In recent years, CLRs have emerged as an information tool for representing mastery-based learning outcomes (Shendy et al., 2019, January 20). The CLR presented to hirers represented learning outcomes in terms of complex cognitive, interpersonal, and intrapersonal skills rather than grades or test scores.

All interviews were transcribed and coded using content analysis and grounded theory to reduce the data to emergent themes and patterns. Interview transcripts were reviewed until no additional themes were found. Findings are represented as participants' experiences with applicant evaluation and educational information within the labor market for entry-level positions.

Findings

Participants indicated hiring is supported by the establishment of talent pipelines – trusted recruitment infrastructures that can include formal partnerships with academic programs and instructors, informal meet-and-greets, and recruitment fairs. Decisions on where to establish pipelines are informed by historical data on current employees, institutional reputation, and curricula. This indicates hirers are looking for scalable ways to develop talent pipelines but may rely on potentially subjective insights into knowledge and ability when deciding where to establish them.

In terms of how summative information is used in hiring, hirers indicate they use summative information as a solution to a data management problem - the sorting and screening of large volumes of applications. The perception that transcripts have poor informational value also often leads to practices of contextualizing information to understand applicants' knowledge and ability; a common example included looking at grade trends to determine if a student was competent in a subject. Interview techniques such as case studies and technical assessments were generally more trusted as a means of understanding knowledge and ability. Case study challenges provide a way of "seeing" cognitive skills in action such as problem solving or critical thinking. A student's reflection on their work portfolio provides an opportunity to demonstrate metacognitive skills and familiarity with a community of practice. While these interview techniques can have a significant impact on a hiring decision, they are not employed until after students have been screened through a review of their resumes or transcripts. Hirers want better representations of students' knowledge and ability as they believe many potentially qualified applicants are screened out of the application process based off of the information contained in their transcripts and resumes.

Reactions to the CLR presented to the participants were generally positive. Participants saw them as useful for presenting verified claims of a student's knowledge and ability and efficiently finding the information they looked for when evaluating applicants. One participant likened them to a LinkedIn page, but with the added benefit of being verified by the college. This demonstrates that new representations of students' abilities are unlikely to be utilized without verification, a key role that colleges can play. Participants who already review portfolios of student work drew parallels between portfolios and CLRs. This is listed as an opportunity because it demonstrates that practices required to review CLRs already exist in some form already. One challenge that emerged in the interviews involves developing representations of complex behavioral skills that are interpretable and believable. For instance, how would evidence about "teamwork" be represented? However, the interview data also reveals that current approaches require hirers to make inferences based on limited information. One solution might be to conceptualize CLRs as a tool for comparing different strengths among applicants rather than as an objective ranking or scoring of twenty-first century learning outcomes.

Implications and conclusion

Innovations in higher education are more likely to succeed if learners perceive them as supportive of their goals; in the case of this work, the goal of finding a desirable first post-graduation job. By studying the explicit and implicit infrastructures that undergird learning and the representation of learning, learning scientists can provide evidence-based guidance for new forms of reporting systems and formats to better align our educational goals with the perceived needs of participants in the system. In the case of the current study, those participants are hiring organizations. The demand for students with twenty-first century knowledge and abilities is hindered by current representations of learning, which in turn hinder the design of educational programs and courses. Expanding the range of ways we describe and document learning also has implications for making educational systems and paths to employment more equitable. This study is a step towards more meaningful assessment and reporting infrastructures.

Why Robots?: Historicizing Engineered Imaginaries and Coded Visions of Learning

Deborah Silvis, Colin Hennessy Elliott
deborah.silvis@usu.edu, colin.hennessyelliott@usu.edu
Utah State University

Abstract: The inclusion of robots, robotics kits, and other automated tools and apps in educational settings leads us to consider hidden assumptions and implicit theories that robots encode. This paper draws critical attention to advances in automation by examining two current uses of robots in learning designs. Drawing on recent ideas in STS (Suchman, 2011) and Critical Code Studies (Benjamin, 2019), we analyze two categories of automated agents- competitive robots built by youth and coding robots used by young children.

One way of reflecting on the past and recalling the history of the learning sciences is through the field's origins in cognitive science and computing. Learning sciences inherited theories of learning from cognitive science's computational model of the mind as an information processor (Collins et al., 1978). Likewise, computer scientists and engineers have applied models of human intelligence to machines to develop devices that learn or that automate learning (Hayles, 2005). These mutual processes of designing learning and designing technologies have built automation and AI into the mainframe of our field. A consequence of the close relationship between learning sciences and robotics is that automation is accepted, well, automatically. This paper explores the questions: *why robots here, in education?* And *why robots, now at this particular historical moment?* Drawing on STS perspectives (Suchman, 2011) and recent advances in Critical Code Studies (Benjamin, 2019), we focus on two types of robots used in learning environments: *competitive robots*, which are built by students and used in robotics competitions and commercially available *coding robots* used to teach programming to young children.

Engineered imaginaries and coded visions of learning

All technologies encode human values, a point that is not lost on STS scholars (Suchman, 2011), but has yet to make it into the mainstream concerns of critically minded scholars of educational technology. While there have been some attempts to open the black boxes of learning technologies (e.g. Lachney & Foster, 2020), there is still much work to do to make AI more transparent for learners and to make visible how inequity gets encoded. If, as Benjamin (2020) incisively said, "most people have been forced to live in somebody else's imagination", how then are robots implicated in engineering inequitable imaginaries? And how are educational settings reproducing the "default settings", even as we design for learning that disrupts or resets established inequities? Robot designs are based in theories of human learning and behavior and often tested on young children, who have been model organisms for AI (Fox Keller, 2007). As robots and automated tools become regular fixtures in learning environments, it is important to consider what theories of learning and axiological assumptions they import and reproduce. As Firth and Robinson (2020) wrote, "there is also an element of futurology in mapping the field [of robot-human relations] because epistemologies prefigure technology creation" (p.12). Robot imaginaries mobilize future-oriented narratives of science fiction and speculative fantasy and animate utopian dreams of engineering a better future as well as dystopian notions of destruction (Richardson, 2015). We wonder what that means for education. Whose future does this help make?

Case 1: Coding robot toys

Coding robots respond to computer science standards and computational thinking frameworks that support learning to program for children as young as Kindergarten age (e.g. Silvis et al., 2020). Their cute construction and affordable price point make commercially available coding toys common features in today's early learning settings. The progenitor of these tools was Papert's (1980) tangible programming floor turtle, the literal embodiment of his "objects to think with," a "relational artifact" designed to support "epistemological pluralism" (Lachney & Foster, 2020). When such toys are used to teach computational thinking and other "21st century skills," we might wonder just what kinds of human-robot relations they support, what worlds they help to make, and what imaginaries they engineer and reproduce. We get some sense of these relations from Evelyn Fox Keller (2007) in "Booting Up Baby," where she describes the recursive reliance of children on robots and robots on children when it comes to thinking computationally. "For whom" and "to what ends" are good questions to ask about these designs and the futures they inspire (Philip et al., 2018). Designers of learning and technology should also recall "from whom" these designs originate and "on whom" they are modeled. Whose babies are we booting up when we bring robots into early learning environments? Who is now being asked to live in those imaginations?

Case 2: Cooperative-competitive robots

Robotics competitions have dramatically increased over the past 20 years across the K-12 educational landscape. FIRST Robotics is a leader in managing and organizing youth robotics competitions, with divisions that span PreK to high school-aged children (FIRST Robotics, 2020). The logic of these competitions has epistemological foundations in constructivism (Lachney & Foster, 2020). Individual teams cooperate to engineer robots with a weight limit of 120 pounds that compete in the highest division. Robot designs are constrained by competition rules, which are remade and unveiled at the beginning of each year. Starting with the competition in mind means that the robot is always under construction over the course of the season. The final robot is therefore a dynamic collective imaginary of the team of youth, mentors, and coaches. For the majority of youth, the robot itself is not the learning technology; rather the team's iterative use of tools, machines, design software and programming ultimately make the robot operate. The robot is a symbolic vision of the relationships between humans and machines (Richardson (2011). Competitions are enmeshed with complex spatial politics around gender and race (Hennessy Elliott, 2020) and relatedly class, as certain teams obviously spend more money on their operations than others. We wonder what relationships emerge between the under-construction robot and the youth participants. What kinds of futures are robots helping to inhabit?

Discussion and significance

Benjamin's (2019) characterization of "the new Jim Code" cautions us to remain critical of how robots, as social and technological systems, might further encode future injustices. Whereas Suchman (2011) asked what figure of the Human is enacted in the design of humanoid robots, we wonder what futures are prefigured by engaging with robots in educational settings. In the case of coding robots, children are both the basis for and target of human-robot interactions. In the case of competitive robots, the robot is always under construction and the team is imagined as a collaborative community, where team culture is a means and outcome of design. Within each, there is also a hidden intent of educational designs that aligns: contributing to future industrial development as part of a skilled workforce which can program (coding robot and cooperative-competitive robot) and collaboratively design, engineer, and program mechanisms capable of addressing problems. We challenge educators and researchers to make opportunities with children and youth to critically engage with the histories of these educational designs and the futures- and learners- that they engineer and help us imagine.

Gesture-Based Representational Challenges for Learning Science with Mixed Reality Technologies

Nitasha Mathayas, Indiana University, nmathaya@iu.edu

Abstract: Studies on gesture-based learning environments show that student science learning is enhanced by gesturing, but few studies describe students' challenges using gesture-augmented technology for learning. I examined students' representational challenges when using a gesture-augmented simulation to learn thermal conduction. Using grounded coding to analyze three middle school students' videos using the simulation, operational and conceptual challenges emerged as pertinent factors impacting their sensemaking. Implications and suggestions for further research follow.

Interest in designing gesture-based digital environments is growing as studies show gesturing shapes students' thinking, learning, and communicating (Church & Goldin-Meadow, 2017). Comprised of a class of embodied Mixed Reality learning environments, gesture-based technology has been shown to enhance student learning (Abrahamson et al., 2020). However, gesturing about scientific concepts in augmented contexts is a novel experience for many students leading to new sensemaking challenges. For gesture-based technology to support student science learning, there is a need to understand what challenges they experience when using gesture-augmented technologies and what instructional supports can support their smooth adoption and engagement with the tool to enhance scientific inquiry.

In this study, I explored students' representational challenges using a gesture-augmented computer simulation to explain thermal conduction to understand how their actions around representing molecules in the computer simulation through gesture impacted their conceptual understanding. The simulation (Figure 1) depicts a molecular model of a spoon with temperature gauges on both ends of the model. A student makes a fist over Leapmotion™ to depict a block of molecules. Wiggling the fist makes one block of molecules (indicated by green color) vibrate faster and the adjacent gauge to show temperature rising. In this way, a student uses a conceptually-congruent gesture (Segal, 2011) to run the simulation and see heat transfer occurring at the molecular level.

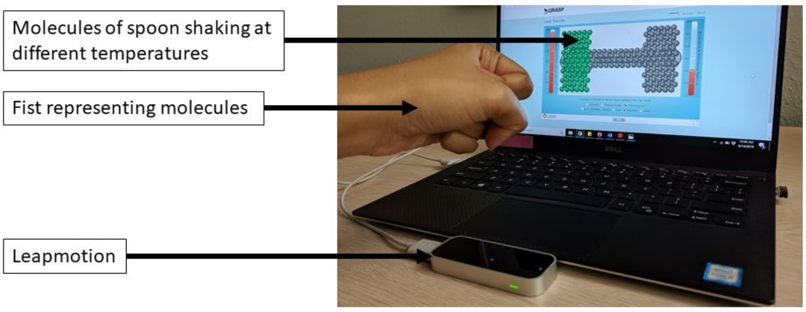

Figure 1. A user shaking their fist to make the left block of molecules shake and the temperature to rise.

Methods

To explore students' interaction with the simulation, I examined video data from a design-research project developing gesture-augmented computer simulations for various physical science topics. In each video, a student was interviewed using the simulation to explain heat transfer through molecular motion. Three eighth-grade students were selected from the data corpus for a case study. These students were selected considering differences in how they made sense of gesture augmentation and the mechanistic nature of their final explanations. Using methods of grounded theory, video was coded for how each student talked about gesture-augmentation. Two kinds of codes emerged, capturing student sensemaking around the *operational* and *conceptual* dimensions of gesturing. These codes were applied to student talk across the length of time of simulation use to explore temporal patterns between codes and the mechanistic nature of their explanations. Preliminary insights from this coding follow.

Findings and discussion

Grounded coding showed two ways students addressed gesture-augmentation while constructing explanations of heat transfer. The first was *operational* and was related to ways they thought gesturing controlled the simulation.

For instance, when Avondre (all names are pseudonyms) used the simulation, he stated, "When I move my fist more, the molecules will move more." This kind of talk showed Avondre establishing the intended understanding of gesture control, but it was also used to capture moments of alternate understandings. For instance, Janine talked about a difference in control between her left hand and her right hand. She explained that "I have more control, I guess, so with this hand [her left hand]. So, it probably was easier for me to shake it and have it go higher instead of this one because it'll lose this one [her right hand]." In this way, this code captured different ways students saw how their gesturing controlled the simulation and it signaled when the gesture became salient to them during their time with the simulation.

The second code addressed the *conceptual* connections students made regarding the representation of gesture in this context. This code indicated when students attended to their hand as representing molecules in the simulation. For instance, Avondre clearly articulated the conceptual connection twice. He first addressed it when introduced to gesture control, and he later stated it again in conjunction with a mechanism for heat transfer by saying, "when I bump my fists together, it represents the green molecules right there, and it bumps into all of them which creates a chain reaction of bumping…" On the other hand, Janine offered a different conceptual connection by saying, "maybe [my fist is] the spoon, like the molecules of the spoon or something. Like, maybe this represents the bowl of it and then like my arm represents the spoon?" In this way, this code indicated when students began appropriating the simulation's gesture as part of a molecular model of heat transfer.

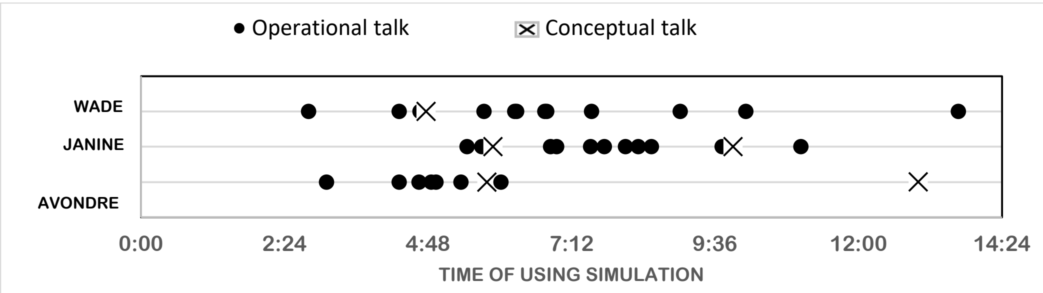

Figure 2. A timeline depicting student talk about gesture while using the simulation.

Finally, for temporal patterns, I plotted each student's code on a timeline and examined the frequency and timing of gesture talk (Figure 2). The plot shows that Wade addressed more operational aspects of gesture while Avondre and Janine addressed a few more conceptual aspects. Given that at the end of the interview, Avondre and Janine described canonically accurate mechanistic models of conduction, whereas Wade's explanation was not canonically accurate, extended talk about operations may indicate a student's difficulty understanding how gesture functions with the simulation. This temporal pattern has implications for simulation design and instruction. While operational talk always occurs with the use of new digital tools, more design research is needed to help reduce students' cognitive load on understanding tool operation. Meanwhile, students are typically unaware of how they can use gestures to support their scientific sensemaking. More research is needed to support students using gestures as tools for modeling and communicating scientific ideas.

Mapping Conceptual Tensions Around Civic Learning

Fabio C. Campos, New York University, fabioc@nyu.edu
Christopher Hoadley, New York University, tophe@nyu.edu

Abstract: Civic education initiatives often display conceptual tensions that render program design a Herculean endeavor. In this poster, we map key civic learning tensions and discuss how they relate to critical topics in the learning sciences field. We find that learning scientists are already well positioned to further understand such tensions and that our research community might benefit from a new research agenda to organize our efforts around civic learning.

Introduction

Understanding that democracy does not run on autopilot, and that a prepared and informed citizenry is a condition for its existence, is a critical learning challenge. Nevertheless, how one teaches or learns about abstractions such as social justice, representation and equality is prone to a variety of conceptual tensions and misalignments. This poster asks *What needs to be learned to attain civic engagement?* We review research from the education, communication and learning sciences (LS) fields to map conceptual tensions crucial for rethinking civic learning in a digital and polarized age and propose a new LS research agenda to respond to this challenge.

Conceptual tensions around civic learning

We define *civic learning* as the body of experiences a person goes through to acquire the various forms of knowledge to participate in the governance (broadly conceived) of a community. It is precisely this broad range of possibilities that afford and magnify the conceptual misalignments we present in this paper.

Tension 1: What is a "Good Citizen"? - The lack of conceptual agreement around what counts as a "good citizen" might hinder the establishment of civic education programs, deepen the exclusion of particular groups, and result in policies and interventions informed by opinions or subjective moral standards. After studying formal and informal civic education programs across the United States, Kahne and Westheimer (2004) found a broad range of views about the characteristics needed for a participant citizen: from loyalty and full compliance with laws and regulations to the ability to critically analyze society and disobey when needed. This model shows that educators view citizenship as the practice of personal responsibilities, often manifested by notions of "character", and civil obedience. Civic programs that place compliance over critique might be favoring behaviors such as obedience, docility and blind loyalty to governments, and failing to advance critical forms of participation.

Tension 2: What counts as "participation"? - Several scholars have called for new theoretical tools to broaden definitions of civic participation. Under these expanded notions, youth engagement with the civic sphere is seen through their participation in *affinity networks*: groups of individuals who share interests, practices and participatory cultures (Ito et al, 2015; Jenkins, 2009). The forms of civic participation that happen through affinity networks conform to what Jenkins and colleagues (2016) defined as *participatory politics* (PP), which are contrasted by the authors with *institutional politics* (IP). Whereas IP depicts civic participation as a domain separated from institutionalized practices, PP are naturally embedded in our daily lives and incorporated into ordinary social and cultural interactions. This understanding has implications to how scholars might frame the challenges of civic learning. The very notion of civic disengagement seems to be under scrutiny by scholars of various fields. Mihailidis and Gerodimos (2016) posit that "expanded learning cultures remain somewhat removed from spaces of formal education" (p. 379), while informal programs have been widely adopting practices that harness youth's interests and contribute to strengthening affinity networks.

Tension 3: What constitutes civic knowledge? Several studies have measured what and how much learners know about civics. In the U.S., for instance, these studies often take the form of surveys and involve knowing facts about branches of government, citizen rights and elections, among other compatible topics. Knowledge *about* elections, rights, and government is no doubt a requirement for a participatory democratic life. However, a question remains whether factual knowledge is enough or if other epistemologies should be considered when thinking about civic learning. For this reason, LS scholars are invited to investigate what other forms might civic knowledge take and how should it translate into designed learning experiences.

Extant studies in the LS describe new literacies as capable of encompassing both factual and practical knowledge about critical participation in society. Mihailidis and Gerodimos (2016) described such literacies as "fluences" for young people to navigate the civic space and acquire the necessary practical skills to act upon it. Similarly, Jenkins (2006) proposed that such fluences are a bridge between in and out of school realities. Finally, researchers such as Ito et al. (2015) and Westheimer and Kahne (2004) argued that internal motivations or personal dispositions are a fundamental piece in the epistemic puzzle of civic activity. *Civic voice*, a term described by Mihailidis and Gerodimos (2016) is "the dispositions and modalities of expression that young people use to participate in daily life". This metacognitive knowledge about oneself resonates with recent work by Jenkins and his team (2016), who collected cases of civic action based on identity building by asking young people "what is your civic superpower?". The results point to identity, self-awareness, and self-efficacy as elements that might be studied, designed, and promoted under an expanded notion of *civic knowledge*.

Towards a civic learning agenda for the learning sciences

Below, we discuss how notions of civic learning in the LS might disrupt problematic conceptions of education:

1. Avoiding "keychain civics". Engagement with civic knowledge must be deep enough to promote civic learning. Blikstein (2013) describes the *keychain syndrome* in maker education where simple engagements with 3D printers to make a keychain impede meaningful interaction and tokenize learning. Keychain civic learning then is where learners engage with basic facts, symbols and myths of origin of a country but never move on to more complex ways of knowing. To avoid it, learning designers need to shift from focusing on factual knowledge in siloed civics courses or short, highly scripted, and self-contained activities to a more complete civic epistemology, including skills and identities, in all learning designs.

2. Civic learning cannot be devoid of civic pedagogies. As civic media rise to address gaps in formal civic learning (Zuckerman, 2016), learning scientists need to ask what pedagogies are needed to be in place so that civic media fulfils its potential. We suggest that civic learning should be thought of not merely as learning of a particular topic (the school subject Civics) but rather as a framework for understanding how learning and education are *always* contextualized by the civic identity, engagement skills or proclivities, and epistemologies of the learner's context as a member of society. Much as Gutiérrez (2014) seeks to embrace syncretic forms of literacies that "support educational, economic, and sociopolitical opportunity for youth from nondominant communities" (p. 49), we argue that all learning environments, within and beyond school walls, can be thought of as a venue for civic learning.

3. Civic pedagogies must honor the diversity of epistemologies beyond the Global North. Much as Freire (1970) called for *epistemologies of the South*, we argue that civic learning must be understood and designed beyond the constraints and traditions of the Global North. More than a mere geographical issue, scholarly work in Northern countries often instantiate a particular epistemology in which knowledge is "by definition fragmentary, imperfect and socially dispersed" (Krašovec, 2013, p. 66). In this view, the learner "wastes no time dwelling on higher truths or grand narratives but possesses and uses only a tiny socially neccesary (sic) quantity of specialised knowledge, one is no longer required to know why, only how." (p. 69).

Materials and Participants: A Dialogical Relationship

Blakely K. Tsurusaki, University of Washington Bothell, btsuru@uw.edu
Carrie Tzou, University of Washington Bothell, tzouct@uw.edu
Laura D. Carsten Conner, University of Alaska Fairbanks, ldconner@alaska.edu

Abstract: Materials play an important role in learning. Humans actors use materials in particular ways depending on the context and materials also can shape how human actors use materials. This study explores the dialogical relationship between the participants and materials in suminagashi, a Japanese paper marbling activity. We found that materials that are traditionally thought of as art materials, such as paintbrushes, are used to support practices often considered science practices, such as experimentation.

Introduction

Scholars have long recognized how materials play a role in learning and that they shape learning experiences in important ways (Gibson, 1977). For example, certain materials are often associated with particular disciplines and practices. A paintbrush can be thought of as a tool used in painting and visual arts, while a microscope may be linked to science and science experiments for closely examining specimen. In previous work, we found that 4-7th grade girls saw specialized materials of science being used for almost predetermined ends, limiting the types of activities or practices that the girls engaged in with those materials (Tsurusaki et al., 2017). Fields such as design studies have pushed conceptualizations of the role of materials to explore the active role they play in shaping the learning context and experience. In other words, there is a dialogical relationship between materials and the designer (Schön, 1992) and material agency is contextual, emergent, and contingent (Tholander, Normark, & Rossitto, 2012). Furthermore, both humans and materials possess agency (Shotter, 2006). We build on the idea that materials and designers are in a dialogical relationship by investigating materiality in STEAM activities with adults. We explore the question: *What is the dialogical relationship between the participants and materials in a STEAM activity?*

Theoretical framework and methods

The meanings that material objects take on are situated within the contexts, narratives, and purposes of their use. Harré (2002) argues that material objects take on different meanings depending on the context of their narratives. For example, a needle may have meanings related to sewing, navigating, or removing a splinter depending on the context. Nasir and Cooks (2009) examine the importance of the role of material resources in learning the practices of a discipline, in this case, how athletes use material resources in the sport of track. Humphries and Smith (2014) argue that material objects "…[are] complex, vibrant and interactive agents capable of influencing and shaping the human experience" (p. 482). How material resources are used shape learning experiences.

While some may examine the use of materials in their final form, such as how a paintbrush or microscope is used (e.g., Harré, 2002; Nasir and Cooks, 2009, Humphries and Smith, 2013), some materials can also change form and the reflexive nature of the materials can impact learning in different ways. Ingold (2011) argues that materials are not fixed, but rather their meaning is made as they are used. It is in the process of creating or making that we draw out the potential of materials through our interactions and relations with them (Ingold, 2013). Therefore, it is our experiences and connections to the materials themselves from which we can draw meaning.

The context for this study was a two day, in-person STEAM professional development program for informal educators in the Northwest U.S. We analyzed the interactions of participants and materials in an activity called suminagashi, a process of paper marbling developed in Japan. Suminagashi inks were dropped into a bin of water, where they floated or sank depending on how the ink was added to the water, the surface tension of the water, and the density of the ink (Figure 1).

Figure 1. Participants dropping suminagashi ink into water bin (left) and paper marbling prints (right)

The participants used the ink bottles, various sizes of brushes, and other objects to apply and manipulate the ink and create designs. Once ink was added to the water, the participants used various types of paper to transfer the ink from the water bin to the paper. Two participants shared one set of materials, which included a water bin, suminagashi inks, brushes, and paper. We videotaped the activity and transcribed the video for dialogue and actions. We used interaction analysis (Jordan and Henderson, 1995) to explore the dialogical relationship between the participants and the materials.

Major findings

What could traditionally be considered art materials, such as paint brushes and inks, are used in this activity to support experimenting and observation, which while they are practices in both art and science, are traditionally considered science practices. We found that examining the dialogical relationship between material and human actors can help us understand how a STEAM activity can support integrative thinking across science and art.

For example, Martha and Leah experimented with the inks and how they behaved in water. They observed that the yellow ink spread out when dropped into the water. Martha suggested that they try a different color ink, green with the same brush, and found that it did not spread like the yellow ink. They shared their observations and hypotheses about whether the brush or some property of the ink caused the different spreading. This episode shows the dialogical relationship between materials, people, and practices. As the materials reacted, the participants responded by experimenting with materials (e.g., trying different colors, brushes) to further explore the materials.

As they continued exploring, they experimented with different sized brushes, using brushes when they were wet or dry ("I think it has worked better when the brush is wet already"), different colors of ink, and placing the paper into the water in different orientations (e.g., dipping it under the surface, placing it on top of the surface, etc.). As they made observations about both how they were using the materials and how the materials were interacting with each other, they explored different ways of using the materials.

Conclusions and implications

As Ingold (2011) argues, materials do not have objective uses apart from the purposes to which they are being put to use. There is a dialogical relationship between materials and participants who engage with materials. The materials shape how participants engage with them in a dialogical relationship. We argue that it is essential to consider the role that materials play, as agentic players, in participant learning and how learning environments are structured to allow for "reflective conversations" (Schon, 2012).

The Heart of the Matter: High School Educators' Experiences of Teaching Project-Based Learning

Avneet Hira, Boston College, avneet.hira@bc.edu
Emma Anderson, Massachusetts Institute of Technology, eanderso@mit.edu

Abstract: In this Work in Progress study, we report on eleven educators' teaching experiences from four high schools that have adopted Project-Based Learning (PBL). A majority of the prior PBL research has been limited to programs or courses within traditional schools, and this work furthers the conversation by capturing the educators' experiences while their schools transform into PBL high schools. We illuminate their early transformational experiences with implications for how teachers are supported in such transitions.

Keywords: Project Based Learning, School Change, Teacher Experience, Teacher Supports

Introduction

The pedagogical practice of Project-Based Learning (PBL) uses projects that engage students in authentic problem solving for teaching and learning. PBL is grounded in constructivist and constructionist learning theories. There has been a breadth of research on the topic, answering questions pertaining to the best practices, student experience, and efficacy of PBL. There have been fewer inquiries about educators' teaching experiences and the factors that contribute to positive teaching experiences for educators. In the limited research on such factors, we notice two broad themes. First, positive experiences resulting from the convergence between teachers' notions of education and the educational attributes that PBL enables. For example, being able to have closer contact with the students (Dahlgreen et al., 1998), being facilitators for student learning (Habók and Nagy, 2016), being oriented towards content learning or career preparation (Rogers et al., 2011), and teachers' intrinsic motivation to teach. Second, positive experiences attributable to situational factors like school context and culture. For example, autonomy over their practice, collegiality (Lam et al., 2010), availability of time to prepare learning activities, being able to scaffold learning experiences, and adjusting to their changing roles as educators (Ertmer and Simmons, 2006).

Methodology

We interviewed eleven high school teachers from four schools across three states in the United States. See table 1 for the teacher pseudonyms along with their school contexts. All four of the schools are part of a network of schools supported by an organization committed to rethinking and changing high school education.

Table 1: Teacher pseudonyms and school background

</table>

We interviewed the teachers between May 11th and June 15th, 2020, using a semi-structured interview protocol. For this paper, we limit our analyses to their perspectives on teaching with a PBL approach. We conducted inductive coding (Patton, 2014) of the interviews to understand what the teachers find exciting about PBL teaching, what they find challenging, and supports that they find most helpful, to contribute to the broader line of inquiry for this paper, which is:

> To understand educators' experiences in high schools that have adopted a Project-Based Learning pedagogy across the curriculum.

Findings

We organize the educators' experiences in three sections below:

I. Exciting aspects of the practice

Three themes emerged on how PBL provides exciting opportunities for teaching. First, the *Enactment of Teachers' Values of Education* theme is about how teachers are able through PBL to teach in a way that highlights their values of quality education. For example, Melissa spoke about being able to take an assets-based approach to teaching. The second theme *Individualized Learning Experiences for Students* highlights the space for student voice. Teachers share how they like the ability to provide dynamic individualized experiences (Eli), to "meet students where they are" (Chloe). The third theme in this category focuses on the *Disruption of Traditional Teaching Practices*. Eric enjoys the freedom to be able to do new types of activities in his classroom, "I love just being able to think of something and then just say, "Can I do that? Oh, I can? That's amazing."

II. What is challenging

Teachers pointed to three common areas of challenge with teaching through a PBL pedagogy. The first focuses on *Crafting Effective Assignments.* Each PBL project has its own final assignment, and the form of that assignment varies. Eric mentions how this openness for creativity in assignments can be overwhelming. Not only is the final assignment a challenge to create but crafting *Relevant Learning Experiences for their Students* can be a hard balance between creating connections to students' lives and accomplishing the goals of the course. As Tiffany, an entrepreneurship educator, pointed out she struggles with wanting her students to find the work they do in her class relevant even when the students may never start their own business. The third challenge that teachers pointed out was how *Transferring Control of Learning to Students* takes a big leap from the teacher in how they approach education. One of the key aspects of PBL is providing space for student voice and choice in their learning. David shares how he is working on being comfortable with not knowing all the answers as a teacher.

III. What supports are helpful

The teachers spoke about two kinds of support that they find helpful for PBL teaching: those found *within* the school and those they sought *outside* of school. All the eleven teachers we interviewed spoke about the *within school supports* including administrators' structural support, such as allocating resources to learning activities. These supports can be less formal as Tiffany shares how the teachers having "lunch together every day" helped share ideas. Five of the teachers highlighted outside of school supports including being part of online communities like teacher Facebook groups (Melissa), visiting other schools and attending events (Denise), and finding frameworks that they can adapt to their settings like those from Stanford D (Naomi) school and PBLworks (Eli).

Implications

Our findings in this work in progress study show that though the types of issues and motivational factors teachers report when teaching PBL are similar across schools, the solutions to overcoming the challenges lie within the schools. This study's findings have implications for how schools can support their teachers. When possible, appoint in-school coaches who are cognizant of the school's context and work with teachers to transform their practice. Outside providers should look to programming that builds capacity at the school level. School-wide transformation cannot be mass-produced across schools but must be created within school communities.

Educational Grantmakers' Conceptualizations of Equity

Heather McCambly, Northwestern University, mccambly@u.northwestern.edu
Krystal Villanosa, Northwestern University, kvillanosa@u.northwestern.edu
Claire Mackevicius, Northwestern University, cmackevicius@u.northwestern.edu

Abstract: This interview study probes educational grantmakers' sensemaking of their foundations' contributions to equity-oriented crises and social movements. We identify emergent themes stemming from how respondents connected their equity commitments to their practice and the ways these connections shifted in the midst of COVID and the Movement for Black Lives. Themes suggest implications for possible futures in educational grantmaking—futures in which grantmakers reimagine their theories of change and power in response to socio-political conditions.

Keywords: Education Philanthropy, Grantmaking, Racial Equity, COVID-19

Introduction

In the midst of the COVID-19 pandemic upsetting daily routines, impacting communities worldwide, and disproportionately infecting and killing Black, Latinx, and Indigenous communities, the murder of George Floyd has renewed attention to the Movement for Black Lives (MBL). Synchronous to these crises, there has been a growing recognition amongst educational grantmakers that the philanthropic field's historical disengagement from racial justice has led foundations to reproduce rather than disrupt inequities in education. The convergence of these phenomena—the magnification of existing inequities and a growing interest in equity among education-focused philanthropies—creates a need for research on the intersection of grantmakers' efforts with equity movements. We conducted interviews with educational grantmakers to surface how they conceptualized their foundations' response to COVID-19, MBL, and the role of equity in their work to examine: 1) whether and how foundations' prior commitments to supporting racial equity are changing, advancing, or declining; and 2) whether and how grantmakers connect these commitments to their grantmaking practices.

Theoretical framework

Prior work has shown that foundations consistently converge around "top-down" and advocacy-focused approaches to influence policymaking, effect systems change and reduce social inequalities (Tompkins-Stange, 2016; Haddad & Reckhow, 2018; Gandara, Rippner, & Ness, 2017). Foundations have increasingly drawn on neoliberal frameworks and strategies, favoring market-based choice policies and institutional arrangements to achieve their goals (Baltodano, 2017; Ravitch, 2016). They have also been known to leverage "bottom-up" approaches, providing resources and legitimacy to social movements seeking to enact community-driven demands. Resource mobilization is a crucial component to the growth and success of social movements seeking to achieve greater social equity (McCarthy & Zald, 1977). As such, a movement's success is contingent on its access to resources. Taking top-down and bottom-up mechanisms together, a vision emerges of foundations as important (albeit problematic) arbiters of racial justice and educational equity. We examine educational grantmakers' understanding of their role in equity responses prompted by COVID-19 and MBL.

Methods, data, setting, and analytic approach

We used a comparative case study design, conducting 30- to 60-minute semi-structured interviews with grantmaking practitioners (e.g. program officers) to explore how they are changing or persisting in their practices in the face of COVID-19 and MBL. We leveraged purposive sampling (Weiss, 1994) to recruit 13 grantmakers from 7 Midwest-based foundations, 3 of which make grants nationally while 4 make regional and local grants. 5 grantmakers identified as Black, 1 as Asian, 5 as white, and 2 as Latinx. 7 identified as female and 6 as male. Interviews were conducted in 2020 and transcribed for analysis. We collaboratively analyzed transcripts, co-developing analytic memos attending to how grantmakers conceptualized their foundation's response to COVID-19 and the role of their philanthropic work in pursuing equity. We leveraged Strauss and Corbin's (1998) process of conceptualizing events to co-identify patterns of meaning revealed in the data, leading to the themes below.

Preliminary findings

Grantmakers' painted a dynamic picture of their sensemaking through reflections on what they have learned through these dual crises. We found that most noted that COVID-19 surfaced new urgency for equity and challenged their beliefs about the "right" balance between long-term strategic investment and addressing immediate, community-based needs (e.g. food, housing). Five grantmakers of color expressed frustration with the lack of urgency among colleagues across philanthropy, articulating questions about *whose* existence—and threats to that existence—matters enough to catalyze urgent philanthropic responses. While some grantmakers voiced intentions to continue top-down and policy-focused work, others questioned whether foundations focused on supporting change and community thriving should fund institutions (e.g. colleges, nonprofits) or attend to students' and families' needs. One grantmaker referred to this tension between strategy and survival as philanthropy's "privilege of patience," arguing that "not everything is about infrastructure or long-term strategy...it's time to respond to the call for some of these basic needs and supports."

Grantmakers also described multiple paths toward universally-professed equity commitments. These split between preservation (investing in existing organizations and approaches) and resourcing communities to challenge institutions. A majority of grantmakers expressed renewed interest in learning directly from the communities they aim to support. Interviewees reported efforts to have more meaningful conversations with Black, Indigenous, and Latinx-led community-based (and/or student-led) organizations about funding than they had before COVID-19. One grantmaker envisioned a model for funding PoC-led organizations, which tend to be in acute need of operating funds, that reflected interviewees' emerging interest in reconnecting with community-based organizations. Moreover, grantmakers described investing in ways that belied trust in organizations' judgement and labor as advocates. Some surfaced that supporting these organizations' autonomy and work in grassroots social movements could produce new pathways toward community thriving.

Two potential implications

First, we suspect that foundations who subscribe(d) to a top-down, systems-change model of philanthropy may be permanently troubled by how COVID-19 and MBL have: 1) made explicit systemic dysfunctions that have led to food insecurity, health-care vulnerability, fragility of cultural institutions, and unstable civil liberties; and 2) created an urgent need to strengthen connections with communities to facilitate community-informed responses. Second, new practices enacted to foster closer philanthropy-community connections may result in changing how foundations form partnerships with, and fund, community-based organizations. Grantmakers who identified as more directly rooted in BIPOC communities hoped that this moment would reveal the need to break up white-dominated networks in favor of more diversified networks of organizations. We predict that preferences for local and PoC-led organizations could gain momentum as grantmakers continue to make sense of the MBL's arguable success in changing racial conversations (i.e. defunding police).

Exploring the Impact of Coursework on Literacy Teacher Candidates' TPACK Development for Technology-integrated Instructional Planning

Huijing Wen, Moravian College, wenh@moravian.edu
Hui Yang, SRI International, huiy@udel.edu
Şule Yılmaz Özden, Sakarya University, sule@sakarya.edu.tr
Valerie Shinas, Lesley University, vshinas@lesley.edu

Abstract: Framed by TPACK and the Technological Integration Planning Cycle, this study explored how a teacher-education course impacted literacy teacher candidates' TPACK development in designing and teaching unit plans and teacher factors related to effective technology integration. Results supported the role of such a coursework, showing teacher candidates' technology use related to content and pedagogy but with variability in TPACK application. Teacher candidates' belief and confidence in technology use influenced their decisions on effective technology integration.

Introduction and theoretical framework

It's acknowledged that literacy instruction in today's school settings should extend beyond print-based reading and writing by teaching students to read, write, synthesize, evaluate and communicate in multimodal ways (Lankshear & Knobel, 2011). Technology offers classroom teachers more opportunities to establish an active and constructive learning environment in which students are able to make inquiry, explore and construct ideas, and solve problems (Goss, Castek, & Manderino, 2016). The challenge lies in how classroom teachers can help their students achieve these goals.

Since its inception, the Technological Pedagogical and Content Knowledge (TPACK; Mishra & Koehler, 2006) has provided a conceptual model for examining teacher candidates' preparation to teach with technology (Figure 1). The TPACK framework informs research examining teacher knowledge for technology integration in educational settings. However, literature has reported several challenges with the TPACK model, including transfer of knowledge to classroom instruction and teacher knowledge development (Doering, Veletsianos, Scharber, & Miller, 2009).

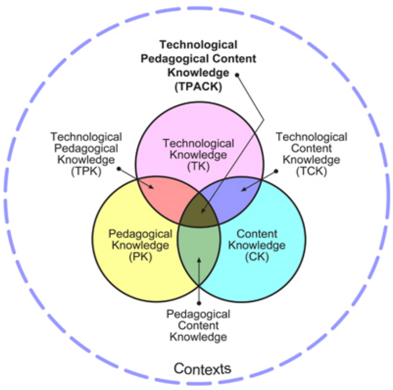

Figure 1. TPACK framework (Mishra & Koehler, 2006).

According to Hutchison and Woodward (2014), to design effective lessons, teachers must identify content focus (CK) and appropriate pedagogy (PK). Importantly, they also need to select and evaluate digital tools (TK) and determine how these can be used to support learning and how they align with content objectives and pedagogical decisions (TPACK) as part of the instructional planning cycle. Thus, the first author redesigned a literacy and technology course framed by TPACK (Mishra & Koehler, 2006) and the instructional planning cycle (Hutchison & Woodward, 2014) with the aim to provide teacher candidates with the knowledge and skills to integrate technology into literacy instruction. By examining artifacts from that course, the study aimed to understand **the impact of the technology-literacy course on teacher candidates' literacy instructional planning and investigate the teacher factors related to effective technology integration**.

Methods

This research was conducted at a small, private university in the Northeast region of the United States that offers undergraduate and graduate teacher licensure and graduate degree programs across a range of disciplines. The study was situated in a required, graduate-level course entitled Integrating Technology into Literacy, which was developed and taught by the first author. The course was designed to explicitly teach the domains of TPACK (Mishra & Koehler, 2006) and prepare candidates to use a TPACK theoretical planning model to design instruction (Hutchison & Woodward, 2014). Twenty-three teacher candidates participated in this study while enrolled in a graduate-level literacy and technology course. All participants were graduate students working toward completion of either a MAT or MA degree in education.

All data in this study were collected from course artifacts: ten-day unit plans and unit-plan reflections. These were analyzed to study teacher candidates' TPACK development through the design and the implementation of technology-integrated lesson plans. Unit plans were analyzed using a valid and reliable four-point rubric developed by Hoffer and Grandgenett (2012). First, unit plans were scored on four criteria aligned with the key components of TPACK framework: 1) curriculum goals and technologies (TCK); 2) instructional strategies and technology (TPK); 3) technology selection(s) (TPACK); and 4) curriculum-based technology use ("Fit"). For this measure, a score of 1 indicates weaker evidence while a score of 4 indicates an advanced level in meeting the criteria.

Findings and discussion

Preliminary findings of the study suggest that there are strong benefits of participation in a technology course focused on literacy. The unit plan analysis revealed that teacher candidates demonstrated stronger TCK and TPK in their instructional plans compared to TPACK and "Fit", indicting their preparation to design lessons that integration technology, pedagogy, and content objects but need for greater attention to developing the more complex domain of TPACK. We further grouped unit plan scores into four categories to better understand the wide variability in scores noted in teacher candidates' abilities to apply TPACK knowledge, based on the overall mean score of TPACK domains: low (22%; between 1 and 2), emerging (26%; 2 to 2.5), developing (35%; 2.5 to 3), high (17%; above 3). Findings from analysis of data across the four groups revealed that 1) teachers who had stronger content knowledge and pedagogical knowledge tended to produce unit plans demonstrating stronger selection of technology tools and clearer evidence of "Fit"; 2) teacher candidates who expressed stronger beliefs about the benefits of technology tended to design unit plans that demonstrated stronger TPACK; 3) teacher candidates who expressed greater confidence m in using technology demonstrated higher levels of TPACK knowledge and application. Results suggest that cognition and affective aspects of teaching influenced teacher candidates' decisions about technology integration.

This study is important to the ISLS audience as it sheds light on how teacher educators can better prepare candidates to use digital tools effectively within pedagogically sound, standards-based lessons. It highlights the need for teacher educators to explicitly teach and support TPACK development among teacher candidates by embedding theory within practice-based experiences such as designing and teaching technology-integrated lessons for the classroom. This work has important implications for teacher education.

Introducing Outside Experts into the Classroom: The Mediating Impact of Instructor Beliefs on the Learner Experience

Kemi Jona, Northeastern University, k.jona@northeastern.edu
Nikki James, Northeastern University, ni.james@northeastern.edu

Abstract: We explore the impact instructor perspectives have on the implementation of a virtual work-based learning intervention in community college classrooms. Drawing upon three years of design-based research, we present case studies that illuminate two divergent educator perspectives. Findings suggest that the ways educators take up and incorporate the intervention into their classroom differentially affects the learners' experience and realized impacts.

Introduction

This paper reports on preliminary insights from a study of the adoption of a technology-mediated "virtual internship" in community college classrooms. Here we examine the experience of two educators who characterize different belief systems and how these beliefs in turn influence the roles, relationships, and outcomes for learners in their classrooms. We explore how an educator's perspective, manifested by their implementation of an educational intervention, impacts the learner experience and can exercise agency within the learning environment.

Starting in 2017, we implemented a virtual internship intervention with the goal of increasing access to industry engaged, work-based learning (WBL) to students, particularly those from low-income, first-generation, and underrepresented (URM) populations in STEM. Using a design-based research methodology (Wang & Hannafin, 2005), we endeavored to get the intervention into the classroom, iterate the design, and then work to scale and spread it throughout institutions. However, the 'getting in' proved more challenging than anticipated, with many implementations withering and dying before they had the opportunity to spread (Cole, 2009). Our research sought to examine potential determinants of success or failure as that intervention is taken up (or not). Educators' beliefs appears to be one of the most determining factors in this process.

To conduct this analysis, we draw on data from 16 colleges implementing virtual internships in their curriculum. All of these schools serve URM and non-traditional students. The researchers served as participant-observers, providing professional development and technical support to instructors both before and during the implementation process. Data collected include: (1) email, and video conference communications between the research team and stakeholders within the implementing institutions; (2) observations and video recordings of educator and industry partner training sessions; and (3) observations from coaching sessions with educators on the use of the data analytics dashboard supporting the virtual internship. Here we focus on an analysis of two educators whose beliefs characterize two perspectives we see emerging from the overall data corpus.

Two emergent perspectives

We illustrate the impact of educator belief or perspective appears to have on the intervention taking root through the lens of two educators' stories, who we will call Ari and Jamie (and use the pronouns they/their for both).

1) Ari is a faculty member at a suburban community college in Massachusetts. The college serves 10,000 students; 67% are students are of color. Ari saw value in the virtual internship, particularly the introduction of an industry coding project with "no right answer," a phrase used by Ari when presenting the virtual internship to their students. The value of welcoming the industry partner project into the learning environment is evident in Ari's approach in the planning phase of implementation. When engaging with a new industry partner to plan the logistics, Ari said, "Once I see the project, I will align the course outcomes," showing a willingness to let the project and industry partner influence the intended learning within the classroom.

Ari's articulated value of an industry partner's project having "no right answer" was also signaled by where Ari situated it within the curriculum. The project begins before students have the technical skills to complete the project. This positions the project as a place where knowledge and skills are developed and refined, not simply assessed. Furthermore, Ari articulated in the project kick-off meeting with students that Ari did not know the answers either, positioning themself as a knowledgeable guide within the project environment in contrast to a holder of the knowledge and solution. When asked how the students work on their virtual internship project is graded, Ari's response was "it's complicated… trying to get away from grading the actual project," an approach that they explain aligns to Feldman's (2019) Grading for Equity that holds accuracy, bias-resistance and intrinsic motivation as its pillars. Instead of grading the project artifacts directly, Ari evaluated each student based on a reflection essay and their ability to explain the code another student contributed to the project.

2) Jamie is a professor at a community college in North Carolina. The college serves 20,000 students with a Black enrollment of 39%. Jamie already had a team project in their course and perceived the virtual internship as a mechanism to bring industry feedback into the classroom. During the planning phase, Jaime made several changes to the intervention design. Two changes most relevant to the present analysis included a) having the students define their own project instead of engaging with a project supplied by industry partners and b) announcing that project artifacts would be graded. These changes repositioned the industry partners from the role of 'project sponsor,' i.e., someone who has a vested interest in the work being produced, to 'industry mentor,' i.e., someone who is using their industry knowledge to suggest possible improvements to the students' project. These moves by Jaime modified the virtual internship model and the industry partner's role to fit within their classroom as opposed to adjusting the learning environment to the design affordances offered by the virtual internship. In a preparatory call between Jamie and the industry partners, Jaime explained the graded artifacts in detail and what asked the industry partners to align their feedback with the grading criteria.

Jaime's decisions during the implementation resulted in moves with lower integrity to the goals of the intervention. When one team had missed a deliverable deadline, platform data indicated that two industry partners had not provided students with feedback on a project artifact. Jaime declined to query or prompt the industry partners about their lack of feedback and instead decided to follow up only with the student team who had missed the deadline. Ideally, a timely intervention by the educator or feedback from the industry partner can inject insight, provide new knowledge or trigger learners' reflective process. Students thus missed out on external input that could have help them construct new knowledge. A discussion between Jaime and the researchers unearthed a hesitancy to intervene in the project process beyond checking on a missed deliverable that would impact a grade.

This positionality of the virtual internship as an assessment tool is reinforced in the way grading was implemented. Student project artifacts were graded against a rubric. Industry partners provided feedback on draft versions of artifacts before being submitted to Jamie for grading. This seemed to position the industry partner's feedback as an optional extra that could add value to the students grade instead of an essential component of the learning. In contrast, Ari did not grade student artifacts, they graded each learner's ability to explain their team members contribution to the project and a reflection essay.

Implications for student learning

The different ways Ari and Jamie took up and implemented virtual internships in their classrooms illustrate how their perspective and instructional moves impact student learning. We are still examining how these and other implementations across a range of settings and populations impact student learning, motivation, career, and attitudinal outcomes. Our findings suggest that the learner's degree of agency while participating in a virtual internship is significantly impacted by their teachers' perspective and subsequent moves in taking up this innovation. Jamie's decision to grade the artifacts reduces the student agency over the experience and precludes the opportunity to learn from failure. Conversely, in Ari's class, where they used Feldman's grading for equity, a learner can fail to deliver a viable project and still passing the class, provided they can appropriately reflect upon and extract sufficient insight from the "failed" project. Our preliminary findings suggest that the different ways that educators incorporate a third-party industry expert into their classroom can dramatically impact the learners' experience and serve to reinforce or undermine the intended benefits of the virtual internship. These findings point to important conversations that should be part of teacher professional development accompanying WBL and similar experiences that engage learners and educators with workplace experiences and outside experts.

Green Chemistry in the Third Age: Engaging Older Adults in Learning about Sustainability

Pryce Davis, University of Nottingham, pryce.davis@nottingham.ac.uk

Abstract: The learning sciences takes a broad interest in learning across lifespans. Yet, there is a lack of research on the learning of older adults and how they engage with pivotal socio-scientific issues. This paper reports on a series of events designed to inform older adults about sustainability. Over 200 participants engaged in discussions with experts around sustainable chemistry. Results demonstrate that these participants learned new things about sustainability and how to mediate environmental concerns.

Introduction

The learning sciences have long conceived itself as a field that takes a broad interest in learning across contexts and lifespans (National Academies of Science, 2018). Yet, there is a lack of LS research are studies and designs that focus on older adult learners of retirement age. Older adults are the fastest-growing age group globally (United Nations, 2019). Despite their relatively proportion of the population, older adults consistently turn out for elections at the highest rates of any age group. What's more, older adults tend to more skeptical of key socio-scientific issues, like global climate change, that will impact the world long after they are gone (Reinhart, 2018). While these socio-poltical concerns are certainly important, at a more basic level we know that a lack of stimulating engagement in learning activities threatens the well-being of older adults—emotionally, socially, and cognitively (Merriam & Baumgartner, 2020). Based on these concerns of improving both the personal and global situation of older adults, this paper reports on the early stages of any exploratory study of outreach efforts to engage older adults in learning activities around issues of sustainability.

Learning in the third age

Three general perspectives inform this work. First, *critical geragogy* refers to approaches to older adult learning the undermine stereotypes of dependency to promote the idea that learning can and should bolster personal freedom and work towards impact social change (Formosa, 2012). This perspective is especially useful in thinking about how older adults might influence the course of discussion around socio-scientific issues like sustainability. Similarly, the idea of *serious leisure* refers to the use of personal "down time" for dedicating pursuits that enrich both the individual and the society (Stebbins, 2007). There is some work that tries to capture pro-environmental actions as a form of serious leisure (Miller, 2018). Finally, and perhaps most importantly, is the concept of the *third age*, which divides the lifespan into "ages" (*first age* being childhood and school-going, *second* being adult working life, and *third* being old age and retirement) to centralize each group's unique needs and abilities (Laslett, 1987). The idea of older adults needing specific learning activities and engagement has led to the emergence of *The University of the Third Age* (U3A), which is an international movement dedicated to providing continuing education and stimulation to retired members of the community in a non-profit structure. Currently, there are over 1,000 U3A groups in the UK which provide community and activities to over 400,000 members (Third Age Trust, 2018). The learning sciences is in a unique position to research and understand how these groups function, in order to help provide learning activities for older adults around the world.

Methods

Since 2018, the School of Chemistry at the University of Nottingham has undertaken a programme of events to engage local U3A groups. At these event, U3A members tour the School of Chemistry's carbon neutral research building and learn how sustainable chemistry research was put into practical use in the design, construction and utilization of the building. The groups also hear formal lectures from faculty members about sustainability and participate in informal conversations and presentations from various students about how to become more engaged in sustainability in everyday life. Each U3A group was given a questionnaire to fill out before and after the activities at the School of Chemistry. The design of the questionnaire evolved over time, but generally involved six or seven closed-ended 10-point Likert scale questions and a few additional open-ended prompts. This analysis focuses on 226 respondents. In addition to the before and after questionnaire, participants were sent a follow-up survey was sent to participants anywhere from three months to a year after their visit. These surveys ask more opened ended questions about whether or not the participant believed they learned anything during their visit, what they may have learned, if they shared information from the activities with others, and whether they changed any day-to-day activities as a result of what they learned.

Results and analysis

Before-and-after survey responses

Before the events, some groups were asked to rate their level of science knowledge on a scale of 1 to 10. The mean score was 4.9 (N = 170, SD = 2.5), which can be interpreted as respondents believing they general have average science knowledge. A paired-sample t-test was performed for all question and showed that there were statistically significant differences for every question before and after the U3A events. This suggests that the U3A events resulted in significant positive shifts for all questions. Fairly dramatic shifts were seen in the respondents' perceived understanding of sustainable chemistry and knowledge of sustainable chemistry research. Views on the importance of chemistry, green chemistry, and chemistry research were high before the event, but still saw a significant shift after. The event also seemed to improve the respondents' views on the environmental impact of green chemistry and the safety of chemistry research. The results suggest that the events had significant impact on the attendees' attitudes toward and understanding of green and sustainable chemistry.

Follow-up survey responses

Nineteen participants responded to the follow-survey. All but one said they had shared information about the activities to others. The open-ended responses revealed that many of them reported about the activities back to their local U3A members at their regular meetings. When asked if they changed anything about their day-to-day lives following the visit, the participants generally said they already try to live sustainably. Others, however, claimed they had made changes, including "recycling more and certainly thinking more about the clothes industry and recycling." When asked what they learned, participants frequently mentioned details about specific topics discussed during their visits. For example, "that oil is not the only means by which plastics can be made." Perhaps the most salient impression from the responses is that participants valued the intergenerational interactions with the university students. Respondents mentioned the enthusiasm of the students and their own interest in hearing about the work being done by younger people. For example, one participant stated, "they were all very keen to show off their work and to listen. It drove home the importance of maintaining and building intergenerational links." In general, the visits seem to have been both enjoyable and informative for the participants who responded. They claimed to have learned new things about sustainability, which they passed onto friends and families and tried to use to inform their own everyday lives. While this is a small sample, the importance of physical, shareable objects and intergenerational communication can be used to inform later iterations of the U3A visits and with other learning activities for older adults.

Conclusion

This work serves as a first step in reengaging the learning sciences with the unique needs and perspectives of older adults. The findings here will inform new iterations of the School of Chemistry's outreach efforts with older communities and individuals. It also begins the process of deriving design principles for older adult learning activities — including the importance of shareable objects and intergenerational interaction — that can be used for new activities. To drive home the urgency of such efforts, I will end with a quote from a participant who after effusing about the visit and his passion for sustainability, said that it is up to others, both old and young, to take up these issues as he is "now in my eighties and with lung disease [and] I'm in lockdown, possibly forever."

GuARdians of Tomorrow: A Compelling Simulation for Understanding Sustainability

Luis E. Pérez Cortés, Jesse Ha, Man Su, Brian Nelson
luis.perezcortes@asu.edu, jesseha@asu.edu, mansu@asu.edu, brian.nelson@asu.edu
Arizona State University

Abstract: We describe the theoretical rationale, design features, and potential implications of the Augmented Reality (AR) simulation we are developing called *GuARdians of Tomorrow*. In this simulation, users experience ramifications of sustainability-related issues by hypothesizing, testing, and perceiving threats of current action (and inaction) on local environmental context in the future through AR. This work will lead to productive discussions about theory-based simulation design for situating long-term, macro impacts of sustainable development into students' local contexts.

Introduction

Critical indicators of Earth's health—global temperature, carbon dioxide, and sea levels—are all on a steady rise (National Aeronautics and Space Administration [NASA], 2020), pointing to alarming trends that could lead to adverse social, technological, economic, and political changes related to sustainability in the near future. These indicators of global health also point to a critical educational need for schools to move beyond teaching abstract, disembodied scientific concepts and instead provide opportunities for students to engage in empathetic, embodied experiences of the social, technological, economic, and political interactions that can be both the causes and effects of sustainability issues. Acknowledging the critical role of schools to prepare scientifically literate citizenry that can productively make sense of and respond to sustainability issues, this poster will describe the rationale, design, and implications of our project, *GuARdians of Tomorrow: A Compelling Simulation for Understanding of Sustainability* (henceforth "*GuARdians*").

GuARdians is a research project in which we are currently designing and developing a mobile augmented reality (AR) simulation intended to address the disembodied spatial-temporal ambiguity of alarming sustainability trends. *GuARdians* addresses spatial disembodiedness by using AR capabilities of mobile devices that superimposes interactive 3D objects and characters based on local social, technological, economic, and political (STEP) data onto the "real world" within the player's local geographical context (in our case, a large urban area in the American Southwest). In doing so, *GuARdians* presents its users with opportunities for exploring their local context (geographical context + STEP data). *GuARdians* also addresses temporal disembodiedness by placing users within an interactive narrative that allows them to simulate what their local context might look like at various points up to 100 years in the future. This simulation will be implemented with middle school students on widely available (Pew, 2019) devices such as mobile phones. Through *GuARdians*, our research team seeks to raise understanding—especially in young people—of the direct, personal, and localized threats associated with global sustainability trends in the future.

GuARdians is designed to be what we call a *compelling simulation*. A compelling simulation results when five key research- and theory-based characteristics are coordinated: 1) **A**gency in the narrative that allows a user's actions to determine how the story unfolds; 2) **R**elevancy to the user's context by using their local geography; 3) **I**mmediacy that focuses on the urgency of local situations by shrinking otherwise large timescales to show warrants for immediate action; 4) **S**caffolds in multiple ways, including adherence to well-established multimedia design principles; and 5) **E**mpathy that requires the user to consider the perspectives of a variety of representative stakeholders. Together, these characteristics comprise the A.R.I.S.E. model that defines a compelling simulation. Each of these five characteristics are inspired by theoretical perspectives that frame learning as inseparable from participating in a system of activities deeply determined by a particular physical and cultural setting (Brown, et al., 1989; Chaiklin & Lave, 1993). As an AR-based compelling simulation, *GuARdians* helps address the National Research Council's (2012) three-dimensional framework of science instruction by incorporating tenets of Situated Learning Theory (Lave & Wenger, 1991) which holds that learning happens best when conducted in authentic environments.

This poster will lead to productive discussions about theory-based approaches for situating long-term impacts of sustainability into relevant contexts for users. In addition, we look forward to discussing our model for compelling simulations with attendees, as we believe it will make meaningful contributions to the field of simulation-based learning by providing a theoretically based design model (the A.R.I.S.E. framework) for designing compelling simulations. This project will also investigate the impact of an AR-based curriculum on students' engagement, self-efficacy, and knowledge gains when approaching complex concepts related to sustainability. Broadly speaking, *GuARdians* will help young people better understand prominent challenges related to ecological sustainability.

Sample images to be used in the poster are included in Figures, 1, 2, and 3.

Developing a Conceptual Framework for Dignity-Affirming Care in Collaborative Research

Robbin Riedy, University of Colorado Boulder, robbin.riedy@colorado.edu

Abstract: Applying a Black womanist perspective, I develop a conceptual framework to explain how two types of care, *validating care in the present* and *validating care for potential* can be used to understand the conditions under which dignity is affirmed in collaborative research.

Collaborative research projects and the potential for dignity-affirming care

The purpose of this paper is to develop a framework that can be used to explore how and when collaborative research settings are *dignity-affirming learning environments* for participants. Collaborative research, as I define it, encompasses a range of ways that researchers engage with school or community partners while doing research *with* rather than *for* and *on* participants (Penuel et al., 2020). An aim of this type of research is the "transformation of the research relationship from one in which communities were objects of study to one in which community members were participating in the inquiry" (Wallerstein & Duran, 2017, p. 28).

Following Espinoza, Vossoughi, and others, I characterize dignity as a "multifaceted sense of a person's value" that "inheres in the person," however, the experience of that is "contingent"; it cannot be taken as a given that a person's dignity will be recognized and affirmed within interactions (Espinoza, Vossoughi, Rose, Poza, 2020, pgs. 1-2). The acknowledgement of intrinsic worth is the result of struggle and social action, such as through education. Dignity involves the ability to feel valued and to value others, but it is a "historical accomplishment," not something received *a priori* (Espinoza & Vossoughi, 2014). This work is concerned with the ways that dignity is accomplished through interaction within collaborative research.

Collaborative research projects contain the potential to be dignity affirming because of their focus on equality, mutuality, and/or reciprocity, in contrast to more traditional, transactional models. The current turn toward more collaborative approaches to research is promising, however, "simply invoking the language and ideals of participation is insufficient" (Shirk, 2012. p. 29). Uncritical attempts at collaboration and participation may actually result in further marginalization as participants are erased and their knowledge and experience commodified. Routinized instances of researchers commodifying, appropriating, and making research participants invisible are still common (Patel, 2015). As collaborative research in the United States takes place within a racist milieu that prioritizes property rights over human rights (Ladson-Billings & Tate, 1995), participants in collaborative research must be vigilant to combat framing research as the property of researchers, rather than as a dignity-conferring activity. Therefore, new ways of thinking about relationships within collaborative research are needed. Black womanists' perspectives on caring provide one model for understanding the caring interactions between research partners that support dignity in research.

Black womanist perspectives and the need for care in research

Scholars that theorize Black womanist caring have firmly linked practices of care to supporting human dignity. For instance, Collins (2009) describes Black mothers' efforts to instill a strong sense of self-worth in their children by meeting their physical needs. Some scholars use Black feminist and womanist interchangeably while others make distinctions, however, both terms refer to theory that centers Black women's experiences and efforts towards self-determination and self-identification within the context of communal liberation. In these traditions, care is reciprocal and mutually beneficial, designed to affirm the humanity, value, and self-esteem of individuals, and to combat negative assessments and stereotypes from dominant cultures (Collins, 2009). Therefore, the aim of care in this practice is the collective benefit and the liberation of everyone, as well as a focus on individual empowerment (Beauboeuf-Lafontant, 2002). Black women's traditions of care attend to the particular history, experiences, and physical reality of people with multiple marginalized identities (Thompson, 1998; Ward, 1995), as well as to understanding how multiple layers of oppression and privilege interact within a power structure defined as a *matrix of domination* (Collins, 2009). Black womanist theories of care view self and communal care, or "mothering," as political action (Collins, 2009; Lorde, 1992). Care is both inward focused and healing, as well as outward oriented and seeking the formation of strategic coalitions (Reagon, 1983).

Connecting care to dignity in collaborative research

Using Sandoval's (2014) idea of conjecture mapping, I reviewed scholarship on collaborative research, dignity, and Black womanist conceptions of caring to map the relationships between design processes in collaborative research, mediating processes related to caring interactions, and the dignity and learning outcomes that collaborative research projects present when caring mediating processes exist. I also reviewed empirical data describing the interactional norms across seven different collaborative research projects.

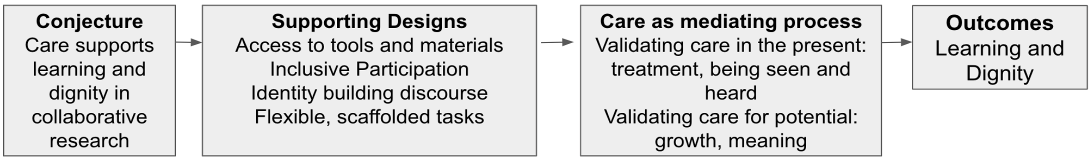

Figure 1. Conceptual Framework for Care and Dignity in Collaborative Research

I find that *validating care for the present* and *validating care for potential* are salient categories for understanding caring interactions within collaborative research. Understanding these facets of caring and how they are present (or not) within the practices of collaborative research projects is one promising step in ensuring that these projects are dignity affirming.

Who Are the Data Scientists in Education? An Investigation of the Identities and Work of Individuals in Diverse Roles

Joshua M. Rosenberg, University of Tennessee, Knoxville, jmrosenberg@utk.edu
Evelina Galas, University of Tennessee, Knoxville, cxx158@vols.utk.edu
K. Bret Staudt Willet, Michigan State University, staudtwi@msu.edu

Abstract: To understand how the new discipline of data science is impacting education and the learning sciences, we surveyed 68 individuals who identified as or worked in roles related to educational data science. Findings from an analysis of the surveys and follow-up interviews with key participants show that educational data scientists have more confidence with the mathematical and substantive aspects of their work (relative to programming) and that beliefs about what educational data science is has a bearing upon who identifies with this new domain.

Introduction

Across education, several new courses, degree programs, and jobs have been created that share a focus on applying novel research methods to new data sources. Such emergent data sources include students' interactions with digital technologies and teachers' participation in online professional learning communities. Although these courses and areas of work have different names (e.g., learning analytics, educational data mining, and educational data science) that reflect different assumptions about education, they also share a number of common features and can be broadly understood as applications of data science methods in education (Wise, 2020), or *data science in education* (Estrellado et al., 2020).

The role of data science in education has been established through foundational (Lee & Wilkerson, 2018) and forward-looking scholarship (Wise, 2020). In addition, efforts have been made to integrate disparate areas of research. However, some core questions pertaining to this new area of scholarship and work remain. Who identifies as an educational data scientist? Are educational data scientists similar to or different from learning analytics and educational data mining researchers? What do individuals across professional roles (e.g., researchers and analysts in educational organizations or school districts) in education who identify as educational data scientists do?

In this early-stage research, we developed and collected responses to a survey of educational data scientists. We then followed-up our survey with interviews of select respondents in order to learn about the identities and work of those individuals from diverse roles who identify as educational data scientists.

Method

We developed a short survey to understand (a) the backgrounds of educational data scientists, (b) their initial ideas regarding their identification with an educational data scientist role, and (c) the nature of their own work. To administer the survey, we shared the questionnaire directly with interested colleagues and asked influential individuals to reshare in their organizations and with their networks. This resulted in a total of 68 responses from individuals in a variety of professional roles.

In addition to questions on individuals' backgrounds, the survey also included questions on (a) whether individuals saw their work as relating to educational data science, (b) their confidence in three aspects of educational data science that have been used to define the domain (Rosenberg et al., 2020)—mathematics and statistics, computer science and programming, and knowledge about teaching, learning, and educational systems—and (c) what software they used in different contexts (e.g., work, in a degree program). The interview protocol we used with three individuals (with the plan to interview more) included 15 questions organized around (a) identification with educational data science, (b) relevant prior experiences, and (c) present work.

As presented in Table 1, we received responses from 21 faculty or post-secondary instructors, six graduate students, 14 data scientists or analysts, 11 K-12 teachers, and seven individuals from other roles, including non-University instructors of data science courses at the post-secondary level. After being presented with a definition of educational data science as an activity or work involving mathematics and statistics, computer science and programming, and knowledge of teaching, learning, and educational systems, most (82%) respondents reported doing educational data science (or related work); 10% of individuals were unsure.

Table 1: Participants' Professional Roles, Self-Reported Genders, and Identification as Under-Represented

Professional Roles	*n*	Does educational data science	Self-reported gender: Female	Self-reported gender: Male	Identification as under-represented
Data Scientist	18	17	5	9	2 (1)
Faculty	21	16	8	13	2 (2)
Graduate Student	6	5	3	3	1 (2)
Teacher	11	7	7	4	6
Other	7	2	5	2	1

Note. Parentheses following values in the identification as under-represented column denote individuals who preferred not to respond. Four individuals did not report a professional role and gender.

Findings

Individuals in our sample reported (using a 1-5 scale, indicating very little to very great confidence) more confidence with teaching, learning, and educational systems ($M = 4.23$, $SD = 0.85$) and mathematics and statistics ($M = 4.22$, $SD = 0.76$) than computer science and programming ($M = 3.55$, $SD = 1.01$). The most widely used software programs were Microsoft Excel, R, and Google Sheets, all three of which were used frequently in individuals' current work; these were followed by Python, SQL, and SPSS. R was used more than any other software in degree programs; Python was second most-frequently-used in this context.

Preliminary analysis of the three interviews revealed that whether individuals identified as educational data scientists—and, if they identified as educational data scientists, with what parts of the domain they identified—distinguished individuals more than the nature of their work or area of study. For example, one individual noted that they thought of educational data science as being focused on "big data" and machine learning. Although this interviewee often used computer programming in their work, they did not consider themselves to be programmers; if educational data science were defined more broadly, they might have been more inclined to identify with it. Another tentative finding pertained to the challenges of analyzing educational data due to its complexity and the individuals at multiple levels (i.e., teachers and students) involved with its production.

Discussion

Our aim with this study was to understand who identifies as an educational data scientist and what people from education-related roles who identify as educational data science do. Our results showed that even among individuals who reported doing educational data science, they were less confident with aspects related to computer science and programming. In addition, we found that a variety of data science tools were used. While R was widely used by individuals in degree programs, other common statistical software (see McNamara, 2018) were also used. Interviews suggested that identifying as an educational data scientist is distinct from doing educational data science (or being in a data science job or degree program), which highlights how both one's identification with a domain as well as recognition by others contribute to individuals identifying as educational data scientists.

The Immune System and Hindu Nationalism: Nation Making in a Grade 8 Biology Lesson

Rishi Krishnamoorthy, Jasmine Y. Ma
sk5303@nyu.edu, j.ma@nyu.edu
New York University

Abstract: We explore how (supposedly objective) science phenomena (the immune system) emerged as co-constituted with the nation-state and the militarization of bodies in a Grade 8 science lesson in South India. The teacher wove narratives of recent military action in the contested region, Kashmir, with explanations of how antibodies activate in the human body. We illuminate how, at the microgenetic level, Hindutva logics shaped students' understandings of scientific concepts, and how this entanglement served Hindu nationalism.

Introduction

On August 6, 2019, in a town outside Chennai (1), Bond (2) began a lesson on the immune system: "You must have heard in the news that in the past few days there is a lot of mobilization of weapons, infantry and all towards the Kashmir border?" Immediately, the class erupted with chatter as students shouted out "Article 370", to Bond's smiling approval. On August 5, 2019, the Indian government abrogated Article 370 in the constitution, making more official India's occupation of Kashmir by imposing added curfews and widespread communication shutdowns (Al Jazeera, 2019). The occupation of an already deeply militarized region was problematically being purported by the Indian government and media as an effort to 'unify the nation', rather than the enactment of a Hindu-nationalist agenda aimed at diluting the Kashmiri Muslim majority to a Hindu majority (Hafsa, 2019).

In the lesson, Bond wove together stories of war and memory cells to describe the ways in which the students' immune systems protected their bodies from pathogens. Science knowledge, typically considered an 'objective' domain, is often described using analogies involving the military and warfare (Martin, 2010). Through the "self/non-self" model (Martin, 2010), the immune system is framed as an army that protects the body against foreign threats, despite research that increasingly recognizes non-static boundaries within human-microbe relations (Gilbert, Sapp, & Tauber, 2012). In this paper we build on research that explicates the use of modern science for engendering Hindu nationalism (Subramaniam, 2019) and highlight one mechanism through which everyday practices in science classrooms reify Hindutva (3) logics implicated in Hindu nation-making in India and the ongoing occupation of Kashmir. We ask: *How did the immune system emerge as co-constituted with the Indian state and military occupation in Kashmir; and with what consequences for nation making through science education in India today?* Through analysis that explores one way that (supposedly objective) science phenomena (the immune system) emerged as co-constituted with the nation-state and the militarization of bodies, we illuminate how the Kashmiri occupation was implicated through science education and simultaneously, how science teaching may serve to naturalize nation-making through postcolonial – Hindutva - logics.

Theoretical framework

We draw on a relational ontology to recognize human-more than human (MTH; Bang & Marin, 2015) boundaries as emergent through encounters (Ahmed, 2000) that are entangled (Barad, 2007) with relationships between "other others" (Ahmed, 2000, p. 8) in the past, present and future space-times. Indigenous ways of knowing (IWOK) stand in sharp contrast with the Eurocentric impositions that assert humans and the MTH as implicitly separate (Bang & Marin, 2015). Recognizing the MTH world as active in co-constructing reality (rather than as the passive recipient or object, of human action or subjectivity) requires a reformulation of how we come to know from knowing the other to knowing in relation (Marin & Bang, 2018). In South India, non-colonial and IWOK are complicated by the caste system where Brahmanical supremacy has and continues to oppress Dalit communities' knowledge systems. 'Indigenous' knowledge systems such as the Vedas are intimately connected with Brahmin supremacy and were historically only accessible to upper caste communities (Subramaniam, 2019). With Brahminical and Dalit ways of knowing both rooted in a relational ontology, we draw on Indigenous scholars from Turtle Island to recognize the commonality in ontological commitments between IWOK globally and those of South Indian and Dalit communities where knowledge creation is emergent in and through deep relationship with the MTH. Therefore, we consider nation-making an ongoing emergence that reifies which relations are positioned as the 'other' through everyday encounters, and we recognize science phenomena emergent in the classroom as entangled with MTH elements inside and outside of the classroom space.

Data and methods

This paper draws on data collected from a larger study that explored the role of materiality in science teaching in a South Indian school. While not explicitly religious, the school exuded strong Hindu and nationalist sentiments, enrolling students and teachers of diverse religions and castes. Data analyzed included field observations (Childers, 2013), field-noting body movements/position of humans and MTH. Using a 2.5-minute audio excerpt of Bond's narration, we took a dialogic approach to analyze the "interactional positioning accomplished" (Wortham, 2001, p. 34) through human utterances. We used micro-ethnographic and interaction analysis (Jordan & Henderson, 1995) methods to examine Bond's narrative that positioned human and MTH entities socially. We examined how particular elements of the immune system entangled with elements of the Kashmir story; how human-MTH entities were positioned through power'd boundary enactments; and how these relations became naturalized as subject-object relations.

Results

In this episode, immunity was not a neutral biological concept. It emerged as political through a Hindutva framing that valued human-nation exceptionalism and necessitated mechanisms of protection against 'foreign' others who might pose a threat in the future. Bond's narrative enacted a boundary that clearly defined the human body (and therefore nation state) as distinct, making it simple to identify and separate "foreign" entities. Bond separated the human body-nation from other MTH entities to protect the integrity of the 'self'. Entities "foreign" (Kashmiris) to the human body-nation boundary would necessarily be a "problem", and were expected to invade eventually, even if "dead or deactivated" now. The immune system-army then, emerged as necessary defense systems not only for protecting the integrity of the human body-nation boundary, but also ensuring that the body-nation would not perish. The power'd boundary enactment justified and naturalized the need for defenses (antibody-weaponry) to "get triggered" automatically against entities (Kashmiri-pathogens) with the potential to "create a problem" in a future space-time. Students' immune systems were not neutral entities in the human body. 'Memory cells-soldiers' detected and attacked foreign 'pathogen-Kashmiris' through the 'antibody-weapon' phenomena, to protect and establish the 'healthy body-country' entity. As Hindu nationalism pervades India, this paper contributes to nuancing *how* the expansionist agenda to occupy Kashmir can be reified through science teaching.

Endnotes

(1) Chennai is a large city in South India, the capital of Tamil Nadu and over 3000Km south of Kashmir
(2) All names are pseudonyms. Bond is a Hindu Brahmin grade 8 biology teacher.
(3) The logics that inform Hindu nationalism with the goal of securing a 'Hindu' nation

Abstract: We examine approaches for fostering critical reflection in a community-oriented MOOC. We used a four-category coding scheme to analyze a sample of learners' journal entries in a digital workbook tool, which was integrated into a MOOC on resilient teaching. Our analysis shows that learners engaged in high levels of reflection across all three weeks of the course. This study offers a promising approach for enabling deep learning and knowledge sharing in large-scale, open-access learning environments.

Introduction

Massive Open Online Courses (MOOCs) have long been associated with transfer-oriented pedagogies and self-paced learning approaches (Eisenberg & Fischer, 2014). However, the self-paced, individualistic nature of MOOCs can hamper opportunities for learners to engage in significant learning in concert with peers.

Given the affordances of MOOC platforms, how can instructors and designers pragmatically advance forms of interaction that support deep comprehension and offer opportunities for meaningful interaction? One possible means is through threaded discussion forums, which are the most widely used venue for communication and social learning in MOOCs. However, discussion forums exhibit problems such as a demonstrable lack of deep reflection by learners. Additionally, the chaotic structure of forums can create a disjointed experience for learners who must piece together fragmented threads (Almatrafi et al., 2018). Given that MOOCs typically utilize a standard, limited set of features, what is needed is an alternative venue for learners to engage in reflective knowledge sharing practices within structured, self-paced environments.

In this study, we examine the role of a new digital workbook tool situated within a MOOC whose stated goal was to foster reflective practices amongst learners—educators and instructional designers grappling with the new realities of "emergency remote teaching," brought on by the COVID-19 pandemic. Integrated into a standard MOOC platform using Learning Technology Interoperability (LTI) protocols, the instructional team utilized the workbook tool to offer learners a space to reflect on course concepts, with the possibility of sharing their reflections with others within an interactive gallery.

Our aim is to investigate the utility of the digital workbook to address known challenges of discussion forums, namely lack of quality responses and disjointed structure. Guiding our inquiry of the use of this new digital workbook are the following research questions:

1. What levels of reflection can we observe in learners' journal entries?
2. To what extent do learners choose to share their journal entries with peers for review and comment?

Relevant literature

In the Learning Sciences, the role of reflection in learning has long been acknowledged as an integral part of the learning process. Boud et al. (2001) characterized reflection as an "intellectual and affective [activity] in which individuals engage to explore their experiences in order to lead to new understandings and appreciations" (p. 19). Within professional learning contexts, Schön's (1983) influential work on the role of reflection "in" and "on" action presents reflection as a catalyst for improving practice.

Research context

This study explores the use of a digital workbook tool for reflective journaling within a MOOC on the topic of Resilient Teaching. Launched in June 2020, the MOOC was developed during the COVID-19 pandemic to support educators who sought effective pedagogical approaches to address instructional challenges in the early phases of the crisis and beyond. Designers of this community-oriented MOOC sought to create a venue for sharing ideas, offering mutual support, and providing mutual encouragement for instructors at all levels (Quintana et al., 2020). The MOOC was composed of four weeks (modules), each consisting of 3-4 hours of instructional content, activities, and assessments. Across the first three weeks, learners were encouraged to engage with 12 workbook prompts, which provided immediate opportunities for learners to reflect on key concepts just after they were introduced throughout the course.

Digital workbook

The MOOC utilized the Gamut Workbook tool, which was integrated into the Coursera platform using LTI protocols. Indexed to specific topics and activities within the MOOC, the workbook tool provided learners with a secure place to save their reflections and facilitated easy retrieval and editing of ideas. Workbook prompts were structured such that workbook entries could serve as the building blocks for a resilient teaching plan, the culminating assignment of the course. Importantly, the tool offered learners the choice to keep journal entries private or to publish them to a gallery, making them available for review and comment by peers.

Method

Data sources

We collected data from the first four months of the Resilient Teaching MOOC. During this time, 2820 learners were "active" participants in the course, meaning that they engaged with at least one course item (e.g., watched a video, or participated in a discussion forum). We analyzed responses to one workbook prompt from each of the first three weeks of the course. From these prompts, we randomly selected 80 responses to ensure that we could analyze an identical number of responses for each prompt, analyzing 240 journal entries in total.

Coding scheme and coding approach

We adopted Kember et al.'s (2008) four-category coding scheme for written work: habitual action, understanding, reflection, and critical reflection. We modified their original categories by removing "habitual action," replacing it with our own term called "isolated action." Our code had a similar meaning, which is that an intended or planned action is described without explicit connection to course concepts. Four coders participated in the coding process, with one pair independently coding 20% of the data for each prompt, resolving disagreement through discussion, and one member of the pair completing coding for the prompt. We applied these codes as discrete categories (i.e., one per journal entry), following our coding book.

Findings and discussion

Our findings show high levels of reflection and critical reflection across all three weeks of the course, with the highest levels occurring in responses to the Week 2 prompt. To explain why the highest levels occurred in week two, we surmise that the variability in the prompts themselves likely influenced the levels of reflection we observed across the prompts we analyzed. In sum, we can see that the quality of reflection within journal entries is high and contrasts vividly with the stark lack of reflection that Almatrafi et al. (2018) noted are characteristic of MOOC discussion forums. Further, as the workbook prompts were indexed to course concepts and were preserved within a logical sequence that was easily retrievable by learners, the issues of disorganized and fragmented threads that Almatrafi et al. (2018) surfaced about MOOC discussion forums were circumvented.

Our findings also show that learners increasingly chose to publish their journal entries to the public gallery, making them available to their peers for review and feedback. Although it is beyond the scope of this study to understand possible reasons for this increase, this finding shows that the use of the workbook tool shows promise for learners to share deep learning within large-scale, open-access environments. Future research will examine how MOOC learners interacted with peer responses in the public gallery of the digital workbook.

Exploring Affordances Provided by Online Non-Curricular Resources to Undergraduate Students Learning Software Development

Andrés Araos, University of Oslo, a.a.a.moya@iped.uio.no
Crina Damşa, University of Oslo, crina.damsa@iped.uio.no

Abstract: This study explored how students learning software development used online non-curricular resources during three months. It combined digital traces, self-reports, interviews and course documents to analyze how these resources provided learning affordances and support for pursuing learning purposes. Findings reveal complex arrangements of people and resources across different contexts, which translated into several interrelated affordances and purposes.

Introduction

Computer and software engineering (CSE) students' learning software development increasingly integrate online ecosystems related to the work of professional developers (e.g., GitHub or Stack Overflow) (Storey et al., 2017). Previous studies indicate students use resources from such ecosystems while learning programming, even when those resources are not integrated in the course curricula (Damşa & Nerland, 2016). Such studies suggest these resources are used for different purposes and that they play a key role in student learning by enabling the access to information, socialization and the understanding of knowledge (Dommet, 2019; Mills et al., 2014). Yet, learning and educational research has given little attention to how student learning happens and what processes are at play when students use such online non-curricular resources.

This study aims at shedding some light on this matter by exploring students' use of online resources that are related to the work of professional developers. It views the use of these resources as part of the enactment of learning practices. Practices are seen as enacted in context, in the form of discursive-material configurations that involve affordances and purposes (Mahon & Kemmis, 2017). That is, relations between abilities of people and the features they perceive in resources (Chemero, 2003), and the subjectivities that explain why these relations are formed (Garrick & Solomon, 1997). Thus, the enactment of practices is analyzed in relation to how resources are 1) used in context (higher education, personal life, work life), 2) how they function as learning affordances (e.g., to communicate, understand concepts, collaborate), and 3) which purposes they help serve (e.g., obtaining future rewards, advancing in tasks, belonging to groups). Different types of data are combined to answer these research questions: RQ1: What people and resources describe students' use of websites connected to professional development? RQ2: How do these relations translate into configurations of contexts, affordances and purposes?

Methods

This study is part of a larger research project that collects different types of data on students' use of online non-curricular resources for learning. Participants were 16 students from CSE programs at four large universities in Norway. Using a mixed-methods design, students were asked to answer a questionnaire about four categories of activities linked to professional developers' work, the websites used for these activities and other background questions. Once submitted, a custom-made software collected three months of digital traces of each website reported. These traces served as an input for stimulated recall interviews (Dempsey, 2010) that explored in-depth the enactment of practices during the three months. The analytical strategy involved two stages. To answer RQ1, qualitative content analysis of the interview data combined with questionnaire responses was applied to identify relations involving people and resources related to the four categories of activities. To answer RQ2, a qualitative analysis of affordances and purposes of the interview data was applied in combination with course documents.

Findings

The findings indicate large arrangements of websites, online resources and people connected to four practices enacted during the three-month period. In total, the enactment of these practices involved 34 different websites and relations with different people, such as teachers, students, friends and professional developers. Groups of people and resources, notably, were sometimes seen more as a single entity than as sums of components. These practices (see Table 1) often wise were enacted simultaneously, in a complementary way, and sometimes different practices were seen as inseparable. The second stage of the analysis revealed practices were enacted in several contexts, including course assignments, daily life situations and business projects, involving relations that translated into different types of learning affordances (see Table 2). These affordances differed greatly between project-based course assignments and theory driven ones, involving different people and types of online resources. Moreover, affordances were also sometimes interrelated with one another and established for different purposes. These purposes included contributing to student groups, family and friend projects, seeking future job opportunities, advancing in programming tasks, understanding concepts, personal interests and diversifying skills.

Table 1: Examples of websites, online resources and people observed in the enactment of practices

Practice	Examples of Websites (# of students)	Examples of Online Resources
1. Problem solving	W3Schools (14), Stack Overflow (15), Google (16), YouTube (16), FB Messenger (10)	Code components, source code, tutorials, text messages, solutions to problems
2. Staying up to date with trends	YouTube (11), Google (9), Stack Overflow (6), GitHub (6), Discord (4), Twitter (3)	Technology news, professional developers opinions
3. Deliberate learning	W3Schools (14), Stack Overflow (12), YouTube (16), Geeks for Geeks (7)	Code components, source code, explanations of concepts and methods
4. Future career management	LinkedIn (4), GitHub (3), Gmail (2), YouTube(2), Google (2)	Job offer descriptions, career guidance blogs

Table 2: Examples of affordances found in the interview data by category

Category	Examples of Affordances	Excerpts from Interview Data
Material Affordances	Communicating, sharing code, and searching for explanations of methods.	"[We] show pictures or prototypes of the app that we made, by screen sharing [on Zoom] (…)".
Mental Affordances	Examining code and looking at explanations of methods or concepts.	"[I] read what they say or try to interpret the code [on Stack Overflow] (…)".
Intersubjective Affordances	Giving and receiving feedback, planning activities, discussing code.	"[They] sit [on Discord] and tell you: 'this is wrong [in your code] because this and this'."
Translation Affordances	Reusing code components into own source code, repeat steps in tutorials.	"[I] copy/paste [code components from Stack Overflow], with tweaks to make it work".

Discussion and conclusion

Findings show learning practices were enacted in ways similar to the work of professional developers (Nerland, 2008). Furthermore, these practices' configurations varied across contexts and involved interrelated learning affordances and purposes that emerged out of complex relations established between different people and online resources. It comes to light from the findings that these relations were central for students' learning processes, and that their purposes cannot be just related to the accomplishment of curricular goals and academic performance. Students used websites and online resources with a future oriented approach that went even beyond graduation itself and that was influenced by people, groups and resources in complex ways. The current project intends to explore further the use of websites and online resources by examining how these configurations are formed.

Reorienting Co-Design toward Care during a Pandemic

Abstract: Care is an essential, but under-conceptualized aspect of successful educational co-design. We reflect on our experiences as researchers co-designing with teachers during the COVID-19 disruption. As researchers, we reframed our goals around an ethics of care to support teachers as they strove, and at times struggled to enact care for their students. We illustrate how co-design might be more dynamically responsive to partners' needs in times of crisis, and potentially lead to more effective outcomes.

Expanding co-design through an ethics of care

Care and kindness are foundations of any relationship, and should ground and propel all education research endeavors. Whereas most research has only focused on care in teacher-students' face-to-face relationships, care should also be embedded in the educational co-design process between teachers and researchers, which in turn can also support care between teachers and students. Crises offer unique opportunities to enact care. Building on related work (Kara & Khoo, 2020), we reflect on how our research team renegotiated our co-design process within an ethics of care amid our early experiences with the COVID-19 pandemic.

Co-design is a partnership between teachers and researchers to develop educational materials that can ensure usability and effectiveness and can lead to increased teachers' increased agency and reflection on their practice, and ownership over the resulting design (Penuel, Roschelle & Shechtman, 2007). Typically, co-designers contend with tensions that arise from differences in values and workplace norms. In times of crisis, these tensions are exacerbated and new ones can arise, such that there is a greater need to be caring and responsive toward teachers', students', and researchers' needs.

Care is expressing concern for others that is manifested in behaviors, emotions, and bonds between individuals). An ethics of care calls for relationships to be constantly negotiated in terms of the roles of "carer" and "cared for" in order to prioritize the needs of others (Bergmark, 2020). Research finds that care in teacher-student relationships positively impacts students' academic engagement, well-being, and self-esteem; as well the meaning that teachers draw from their work (Lavy & Naama-Ghanayim, 2020). However, nurturing caring relationships assumes that teachers and learners are co-located, and can rely on routines to enact care. For example, when students attend in-person class, teachers can notice whether they are academically disengaged. Teachers can also use formal and informal opportunities for dialog to enact care (e.g., in the school hallways, during class discussion). Crises introduce uncertainty in the conditions of learning, but they also introduce new opportunities for enacting care. We extend the notion of *knowing* and *responding* in education from what has traditionally focused on domain understanding and professional routines, to also focus on personal experiences. We examine how we, as researchers partnering with teachers, re-oriented our co-design process during the pandemic, and with the goal of enabling teachers to better respond to, and care for their students.

Participants and context: A co-design process disrupted

This work emerges from the Data Literacy through Art project, an effort to design and explore the value of an arts-based curriculum for supporting data literacy. Our co-design team comprised 7 cross-institution researchers, a middle school art teacher, and a middle school math teacher from the same school. During the previous and first year of the project, we spent a day in in-person art-making and data exploration to identify disciplinary synergies, and to generate initial ideas for an interdisciplinary classroom unit. Throughout the following academic year, our team of teachers and researchers held regular meetings to co-develop those units in preparation for a Spring 2020 classroom implementation. By March 2020, New York City schools had closed due to the pandemic, and classroom activities shifted to be asynchronous and online; university IRBs suspended in-person research; and several team members struggled to balance their home and work routines. Despite these challenges, our teacher partners felt that continuing with the curriculum implementation would be worth the effort to engage students with the content. Thus, our research team strategized how to adapt our project given new restrictions in what we could observe and learn from the students for whom we designed.

Methods and findings: Re-orienting co-design toward care and compassion

We video recorded eight 1-hour long co-design sessions leading up to, and during the unit's teachers' implementation, and an individual 1-hour post-implementation interview with each teacher. Our research team read through these transcripts, and through an inductive process (Strauss & Corbin, 1998), we identified how we adapted our activities to align with the ethics of care. In the moment, these adaptations felt to be instinctive reactions to new constraints. In identifying our process and design decisions, what spurred those decisions, and our intentions behind them, we came to view them to be aligned with an ethics of care. We outline them below.

Find alternative ways to connect to students. Without in-person interaction, we came to lean on teachers' contact with students to inform potentially compelling activities, and to address students' emerging needs. Our co-design meetings furthermore became essential for us to reflect together on student work, and to notice aspects of learning that we could not observe ourselves.

Use circumstances as learning opportunities. At the time of implementation, the city was under lockdown and students were learning from home. According to the teachers, students struggled to focus, and some who were typically engaged had begun to miss assignments. We thus abandoned our attempts to align the unit to standards, and turned to allowing students to reflect on their current circumstances. We created a series of activities in which students collected data to describe their lock-down experiences (e.g. 'How many times you hear the word "pandemic"? and 'With whom, when, and how do you have conversations?'), and then communicate their findings through individual artworks. To account for home distractions and uncertain technology and materials access, we extended the unit from 5 days to 3 weeks, and had students use household items to create a data sculpture that represents their perspectives and the data that they explored.

Create social connections for learning. The school's mandated asynchronous format, designed to accommodate families' home-bound schedules, meant there were fewer opportunities for peer and teacher feedback and for teachers to engage students in the dialogue that is central to care. We thus created a digital bulletin board in Padlet for students to share their artwork. One of our team members joined to support the teachers in commenting on students' work, which created chances for students to share ideas with an external audience. While this promoted some students' participation, the teachers noted that it was still not a substitute for in-person peer and teacher interaction. This highlights the difficulties of a remote format for enacting certain forms of care, and the need to consider further solutions.

Significance

We argue that researchers and teachers must show mutual care for themselves and students in any design process for learning, and particularly so in times of crisis. Given similar circumstances in which personal contact is limited, future work might explore how, through co-design, we can make students' needs more visible to teachers (e.g., opportunities to share impacts of their personal situations). In revealing our process of adapting to our project's changing circumstances, we highlight how care, as a guiding principle, can create new opportunities for teaching, learning, and research.

Teacher Roles in Prison Learning: Contradictions and Provocations

Joanna Weidler-Lewis, Colby College, weidlerl@colorado.edu

Abstract: As the Learning Sciences continues to investigate teacher learning, it is important to recognize the myriad and complex contexts teachers may be a part. This poster explores initial findings from an interview study of teachers who teach in prisons. I draw on social practice theories of learning and concepts of 'emotional relationality' and 'transformational possibility' to argue that teaching in prison requires a level of care and love that calls into question any other normative claims of teaching in these contexts.

Introduction

The significant role teachers play in contexts of learning is getting attention throughout the field of the Learning Sciences. For example, ICLS 2020 explicitly suggested we as a field apply our critical methodologies to teacher learning (Gresalfi & Horn, 2020). This poster contributes to this aim of expanding our understanding of teaching in an effort to inform learning theory more generally and how to design for learning in different settings. In line with this year's theme of "reflecting the past and embracing the future," this work reimagines traditional roles of teaching and embraces how teachers are relational and emotive actors in learning systems.

This poster explores initial findings from an on-going study of increasing STEM teaching and learning in prisons. In preparation for the study, I interviewed 36 teachers from a variety of disciplines on their experiences teaching both inside incarceration facilities as well as in traditional classrooms. Prisons present a unique context for researching teaching and learning as they are contested spaces with a myriad of contradictions that unsettle your assumptions. It extends research that recognizes teacher beliefs and decision making for instruction are important to how we support and design learning environments (Cobb, Zhao & Dean, 2009).

Theoretical perspective and conceptual framework

The poster takes a broadly socio-cultural perspective on learning and more specifically draws on ideas from social practice theory to argue that learning is contextual, situated in activity, and an ontological process of coming to be of persons, practices and tools (Weidler-Lewis, Wooten, McDonald, 2020). This perspective entails that teaching itself is a situated social practice and previous scholarship has demonstrated how teaching is constituted relationally between learners in cultural communities (e.g., Cazden, 2001). Attending to the social dimensions of teaching highlights how learning occurs through the interaction between teachers, students, and settings (Greeno, 1998; Horn & Little, 2010).

This work centers how teachers create the relationships between themselves and their students, content, and contexts (Liston, 2004). Teaching is a process that is emotional, relational, and personal (Nieto, 2003) Many have argued teaching requires not only respect for students but heart, love, and a belief in the transformational power of education (Parker, 1997; Nieto, 2003). Liston (2004) argues: "At the core of an educational experience are a felt sense of awe and wonder, an encounter marked with struggle and frustration, and understandings that are precious and transforming" (p. 459). Similarly, Nieto (2003) suggests that good teachers imagine the possibilities for their students beyond the dire circumstances in which many of them live. I combine these teacher education theorists with social practice theory to foreground two primary conceptual understandings. First, the 'emotive relationality' that is captured in both the essence of Liston's (2004) notion of "love" and Parker's (1997) notion of "heart" foregrounds the direct relation between teacher and student. Second, 'transformational possibility' relates to students' understanding of self-growth and/or changes in institutional and material configurations; both of which are facilitated by the teacher situated in a learning context. This research seeks to better articulate the salient features of teacher facilitation by answering the question: *what relational roles do teachers fill in STEM learning contexts in prisons?*

Background and methods

An impetus for this study was to inform my work implementing STEM learning in prisons. Interview respondents were solicited through a listserv supporting higher education in prison contexts. The only criteria for participation was experience teaching both inside prisons and in traditional classroom and was not restricted to STEM disciplines. I used a structured interview protocol which included questions about content taught, challenges and rewards teaching in prisons, and how traditional classroom practices shifted or not based on experience teaching students incarcerated.

To date 36 interviews have been conducted with teachers from a variety of disciplines and prison programs. Interviews lasted between 30 and 60 minutes. The majority were conducted via video-conference. All audio was recorded and then transcribed. The transcripts were coded deductively according to emotional relationality and transformational possibility and then inductively. Case narratives (Yin, 2009) were written for select participants based on their representativeness of common themes.

Findings

My findings suggest there is a spectrum of relation roles dependent on the variation between: agency and structure, the individual and community, and knowledge for its own sake and as a means towards a liberated future. Every interview was evocative and prevented any quick judgment of the teachers' beliefs and practices. Because of this, contradictions were rampant. However, normative judgments recede when the complexity of the context emerges, thereby challenging any prescriptive claims regarding what roles *ought* teachers play.

I highlight three roles that represent different places on the spectrum. First is Jan, the benevolent disciplinary expert. Jan sees power in knowledge of her discipline, astrophysics and its reliance on math. Since math is the language of science, without it: "you're not going to get anywhere...and there's no use pretending you are." She revels when her students master the content. Next, is Rebecca, the sympathetic intermediary. Unlike Jan, Rebecca hated math and sympathizes with her students that say math is scary. "Algebra is terrifying to a felon. I always joke that these guys - if they knew they were going to have to take algebra when they came to prison, they would not have gotten in trouble." She sees her role as finding the means to help students conquer their fears. Then, there is David, the empathetic preceptor. He attends to the systemic problems of drug addiction rampant in prison contexts and sees the need for systems to bear responsibility that have criminalized health problems. Jan locates transformation in individuals whether they are teachers or students; Rebecca foregrounds changes to systems and practices that can support students' who lack testing abilities; and David analyses the interplay between the individual and society.

Discussion and conclusion

Although these instructors seemingly rest on a continuum of where they locate possibilities for transformation, it remains unclear whether any value ought to be assigned to this continuum. Each teacher has evidence for "success" of their students whether it is being able to help a daughter with homework, obtain a high school diploma, or have a new outlook on life. Embracing learning as a relation between teachers, students, and contexts entails that multiple configurations of teacher-student-goal relations will be present. Furthermore, the cases presented here are a reminder that both schools and prisons exist in socio-political contexts that present challenges to teachers who view their profession as a liberatory project that amplifies access to not only further educational opportunities but also economic and democratic opportunities (Nieto, 1992). There ought to be more than one path to liberation.

The most salient constant of these teachers is their care and love for their students, and their belief in their students' futures. As we as a field continue to apply our knowledge and methods towards teacher learning, we ought to remain vigilant that we do not interfere with this care and love, because in some spaces, like prisons, students are unlikely to have any future without them.

“You Get to See for Yourself”: Immersive Media to Facilitate Observation and Engagement in Remote Schooling

Eileen McGivney, Harvard University, eileen_mcgivney@g.harvard.edu

Abstract: With protracted school closures forcing young people to learn remotely, schools are in urgent need of innovative approaches that can keep students engaged in their education and support their learning. This poster describes a pilot using Google Cardboard virtual reality viewers and 360-degree videos in remote high school science classes to help motivate and engage students. Early findings from interviews indicate students find them engaging and may be particularly useful for facilitating observational learning.

Introduction

Disruptions to traditional schooling due to COVID-19 are likely to have effects far into the future, including increased high school dropout due to students disengaging from school (McKinsey, 2020). Innovative approaches that create engaging activities and make learning more relevant can be an important strategy for dropout prevention in remote schooling (Kassner et al., 2020). Immersive technology has the potential to increase student engagement, as the sense of “being there” in a virtual space can impact motivation and interest (Dede et al., 2017), including by increasing their focus and attention (Bailenson et al., 2008) and facilitating implicit or observational learning (Slater, 2017). Even short virtual reality (VR) experiences with engaging content may make a difference for students in remote classes that often rely on lectures and static materials, but little is known about their feasibility and effectiveness in this context. Given the myriad distractions young people currently face, and scarcity of engaging and observational learning opportunities, this poster describes a pilot integrating activities that use cardboard VR viewers and 360-degree videos within remote high school engineering classes.

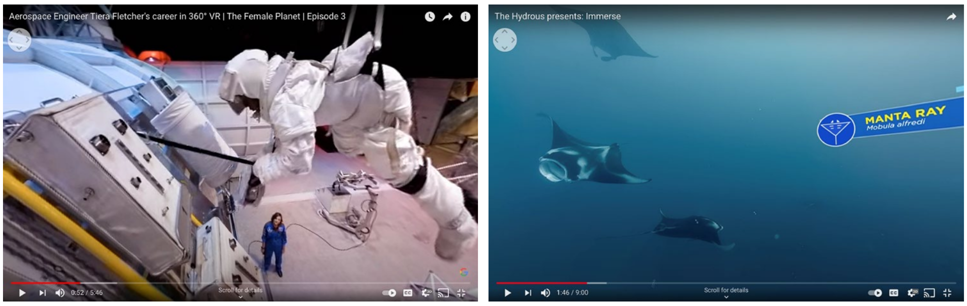

Figure 1. 360 videos used in class. Left: *Aerospace Engineer Tiera Fletcher's Career* (Google). Right: *Immerse: Journey into the Deep Sea* (The Hydrous)

Intervention

This study was conducted in two engineering classes at a public charter high school in a Boston-area midsize city, serving students of whom 100% are eligible for free/reduced-price lunch, 87% are Black or Hispanic, and 13% are English Language Learners. Sixteen of 30 students opted in to the research: seven 12th-grade and nine 11th-grade students, three identify as female and 13 as male. 14 students’ parents, and two students themselves, were born outside the United States. Students are referred to here by pseudonyms.

Initial activities were conducted with five students as one-on-one virtual interviews with the author. Students watched 3-5 videos about structures around the globe related to their engineering projects with a Google Cardboard, and completed pre- and post-surveys and interviews. The second phase consisted of whole-class activities in which all students viewed a 360-video followed by discussions in Zoom breakout rooms. Students participating in the research filled out pre- and post-surveys, and their discussions were recorded and facilitated as focus groups. These activities included a Google video about aerospace engineer Tiera Fletcher and The Hydrous virtual dive about climate change and coral reefs (see Figure 1). The final activity asked students to work in small groups to choose and watch videos together in Zoom breakout rooms.

This poster describes students’ experiences based on interview and focus group data, which were transcribed and analyzed following a flexible thematic coding procedure (Deterding & Waters, 2018). Findings are presented based on the “big picture” themes that emerged from coding by the author and a research assistant.

Student experiences in remote school: “Harder to learn”

Students discussed it being “harder to learn” (Maya) remotely, particularly concepts or subjects they find difficult, where they need to go in-depth, or when material is fast-paced. Students attributed this difficulty to a lack of time with teachers and peers, as well as feeling unmotivated. As Diana put it: “I just feel that [online learning] makes me unmotivated. I don’t want to do it, but I just have to.” They attributed lack of motivation in part to materials, media, and technology in their remote class activities. For instance, Nora said videos and other materials used are not interesting, and “I don’t want to do work at home, I want to watch YouTube, so I am very distracted.” Maya said she finds online classes lacking because she is a “hands-on, visual learner.” Jack described how he missed “the environment” of being in school, and he is discouraged: “I put in a lot, [but] learn less.”

360-degree videos are “more engaging” and facilitate observation

Most students described the videos as *engaging*, demanding focus because “you can’t take your eyes off of it…you have to give your complete attention to it” (Diana) and “because it’s everywhere, it’s all you can see” (Nora). Others described it feeling more “interactive,” because “you can control it, and there’s multiple stuff to look at” (Matthew) and “I can look at what I want to” (Logan). They also found the videos engaging as they related to their interests in travel, careers in engineering, and the environment. Even despite not being very passionate about climate change, Logan said, “I was surprised at how engaged I was” by the beauty of the virtual dive. This may indicate potential for VR to leverage students’ intrinsic motivation if they tie course content to students’ interests and help develop new interests. It is important to note students also discussed the limitations of the media. Students who had tried other VR equipment noted it would feel more immersive if it was a higher quality and more interactive. Others were uncomfortable holding their phones, and felt dizzy or motion sickness.

A theme that emerged from interviews is that students described the benefit of immersive videos as being able to more deeply observe than they have the opportunity to do in other online class activities. Logan felt this through increased agency, “I found it more interesting to be able to look around and look at specific things I want to look at.” Nora described this in contrast to more typical instruction: “You just kind of follow them around and just observe… instead of talking at you, you get to see for yourself.”

This deeper observation may help students learn about places and phenomena in a way that is particularly difficult in remote schooling. Logan described the virtual dive as very useful to show “how beautiful the ocean looked…during the pandemic VR gives us—closer to reality, to a more interactive experience.” And for Maya it made her feel “okay with the quarantine… especially now that we can’t [travel], this is like the next best thing.” The ability to look around freely and at different angles also made it easier for them to understand the environment.

Conclusions

This small pilot points to interesting findings to inform future work. First, students are clearly struggling with remote schooling, and they feel their learning is suffering. Given the likelihood that this and many other schools will remain online for the foreseeable future, schools urgently need to find solutions to support them, to increase their engagement, and help make learning easier. While the intervention described here, utilizing immersive videos and cardboard headsets, will not address many of the students’ challenges, the pilot suggests they may be helpful in engaging students and giving them a different way to work with curricular materials.

Datafication in Figured Worlds: Narrating COVID-19 Data

Josh Radinsky, University of Illinois, Chicago, joshuar@uic.edu
Iris Tabak, Ben-Gurion University of the Negev, itabak@bgu.ac.il
Aleksandra Adach, University of Illinois, Chicago, aadach3@uic.edu

Abstract: The COVID19 pandemic offers an opportunity to inspect how people make sense of the world with data in their everyday lives. Using a theoretical framework based on the construct of *figured worlds,* we conducted think-aloud interviews to study the ways people narrate their routines with data during the pandemic. The analysis enabled us to characterize people's constructions of their agency as interpreters of data; the ways they manage the uncertainties of data; their data-mediated judgements and decisions during the pandemic. These constructions of agency and identity in a data-infused world help us understand both how we learn about the pandemic with data, and more generally, how data mediates our learning about the social world.

Data and data representations permeate many facets of our lives (Couldry, 2018): how we make decisions, and define social structures and positions, such as race, justice, health or pathology (Dourish & Gómez Cruz, 2018). Data interpretations and reasoning with data "play an ever more important role in decision-making and knowledge about the world" (Kennedy, Hill, Aiello, & Allen, 2016, p. 715). Understanding the ways people reason with data in everyday life is key for better preparing learners for civic participation in a datafied world (Feinstein, Allen, & Jenkins, 2013; Rubin, 2020). The information ecosystems (Bhargava, Deahl, Letouzé, Noonan, Sangokoya & Shoup, 2015) around COVID19 present a valuable context in which to examine everyday data literacy. The kinds of information-seeking, sensemaking, and critical judgments that people engage in as they try to understand the pandemic provide a rare window into how people engage with data in a way that is personally meaningful and consequential. We present an analysis of diverse people's interpretations of COVID-19 data representations.

Theoretical framing

We draw on Holland, Lachiotte, Skinner and Cain's (1998) framework of *figured worlds*, which are "socially and culturally constructed realm[s] of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (p. 52). For Holland et al, people are constantly constructing the figured worlds in which they live and narrate themselves and others into relationships in which their agency and identity are positioned in particular, culturally-embedded ways. The narratives that people tell about their use of data (Radinsky, 2020) enable us to see the meanings that they attribute to the resources that they regularly use.

Methods

We conducted semi-structured, task-based interviews in which we asked people to re-enact (using think-aloud) their routine practices with online data and other sources of COVID information. We analyzed the interview transcripts using content analysis and an immersion approach (Crabtree & Miller, 1999) based on the figured worlds framework. We present a set of illustrative examples drawn from 6 interviews, based on initial analysis of a subset of data from a study that is still under way.

Findings

We identified diverse data routines across participants, each of whom was easily able to describe routine information-seeking practices they had developed since the onset of the pandemic. In their descriptions of these routines, we found that people narrated figured worlds in which they were positioned in notably different ways with respect to the data, and to the represented-world phenomena that those data described. Here we present brief, illustrative examples of some of these findings.

Degree and forms of agency as interpreters of data

Interviewees positioned themselves differently in terms of their own agency as consumers and interpreters of COVID19 data. Some described situations in which they would regularly seek out particular information, but were not sure why those data were important, and offloaded the decision-making agency to others:

> I would just check this as an update to know, like, what's the situation in [my country], mostly to see if it's good, bad, or it's or if it's getting better. … I don't remember how they said it, you

> have to do like people per million cases or something, that's also another calculation that they do. … I don't remember 100%, I could be wrong. [P4]

In contrast, others positioned themselves as critical consumers of data with specific expectations, based on how they intended to interpret and use the data:

> And also trying to find sources that show numbers per population, because just the numbers by themselves aren't as helpful if they're not referenced to, you know, the same, per 100,000 people or something like that. … Like just the other day I was trying to compare [my country] and the US. And I was like, That's not very helpful because their populations are different. So unless I can find a source that just shows percentage, or unless I calculate percentage myself, which I've done, it's not – the population is so different, where it's not worth comparing. [P5]

Judgments and decisions mediated by data

Participants positioned themselves as critics of various public policy decisions, narrating scenarios to illustrate why their judgments made sense, and to applaud or critique others' judgments:

> Some of the decisions made didn't make sense, were not rational. … people could have weddings and other religious events [where] we have 250 people participating, when everyone knows that the chances of physical distancing at an event like that are zero. Whereas other events [were prohibited] -- such as cinema, theatre, where it's relatively easy to make sure that there's physical distancing, simply because these are events where people have a ticket assigned to a particular seat. [P3]

Judgments of reasonableness and safety colored many of the characterizations of data, which were often recruited as evidence to support or refute a particular policy argument:

> In the beginning, … you would think maybe wearing a mask is not – at first there was not a lot of data to support [the idea that] it's going to help, [we] mostly thought that it helps people who are sick [not] to spread. But now, since you don't know who's sick, then everybody should wear a mask. Those kinds of arguments changed over time. [P6]

These policy judgments were interwoven with descriptions of data and characterizations of societal phenomena, such that interpretation of data and evaluation of policy decisions were often inseparable.

Discussion and conclusion

Data interpretation involves more than cognitive skills and statistical algorithms. When people interpret data as part of their everyday lives, and in ways that have high personal stakes, it is part of a discursive process through which identities are constructed and relationships are negotiated. During this period of the COVID19 pandemic, data constitute an important resource with which people are constructing complex social realities. Our interviewees constructed different narratives mediated by differences in their information-seeking and data-consumption routines. These differences were not determined simply by the sources they used; rather, they were manifested in different narratives that positioned themselves, the data, and the people, places and policies of the represented world in markedly different ways. A robust understanding of data literacy will be informed by an understanding of the ways in which data function within people's narrations as participants in figured worlds.

Discursive Identity Negotiation through Questioning in Student Presentations of Learning

Stephen Sommer, stephen.sommer@colorado.edu, University of Colorado Boulder

Abstract: This study considers how high school students from diverse backgrounds work to discursively construct their own identities in a learning community through *presentations of learning.* At one school in the Western United States students prepare presentations to highlight major learnings, in and out of the classroom. While students do prepare scripted presentations, analysis suggests much of the articulation of students' evolving identities happen collaboratively through the discursive practice of fielding unanticipated questions from audience members.

Research context

The research site is an alternative, independent residential school, with students recruited primarily from urban communities. While the particular criteria for admission vary on a case-to-case basis, all students were 'otherwise not finding success' in traditional learning environments. Each term students design and perform public facing "Presentations of Learning" which consist of both scripted performances regarding academic content and personal growth followed by an open question period. These unscripted questions offered by peers, faculty, and community members provide and command an invitation for student introspection and articulation about their own personal development, identity in the community, and broader agency in their social worlds.

Conceptual framing and methods

The presentations of learning (POLs) offer an avenue for students to articulate a social identity through narrative performance. Here, I follow Bucholtz & Hall's (2005) understanding that identity is an emergent product of linguistic and semiotic interaction, not a constant internal state that endures in an individual. While students at this site do show some unifying consistent self-narrative, much of the purpose of the POL is to demonstrate growth through time and change since previous trimesters. Identity might also be considered more as a trajectory of short performances that create an evolving narrative chain manifest through speech events (Wortham & Rhodes, 2015). Through these repeated performances, student presenters work to establish both stance and position in their communities. Positioning and stance involve a justification of why a position is taken, and also includes the anticipation or criticism of contrary opinions by other people in contexts. Students prepare for questions from the guest panel and peers prior to the POL and then defend their claims against perhaps unanticipated forms of inquiry.

Ideas, identities, and narratives draw and build upon prior public instantiations and discourse (Wortham & Rhodes, 2015). Many of the ideas students hold about self -dentification 'in their head' perhaps are more accurately conceived of as happening through public discourse. This idea is in concert with Vygotsky's 'general genetic law,' which suggests learners first participate in the social exchange of cultural tools and ideas on the *inter*-mental plane (public) and later take up these ideas on the individual or *intra*-mental plane (Polman, 2010). In this sense, private thoughts and public discourse happen dialogically. All meta-cognitive reflection is mediated by public inter-semiosis. The sort of facilitated public dialogue in events like POLs allows for participants to develop shared vocabularies, thus allowing groups to collaboratively access and generate new reflective awareness of their own experiences situated within a community of practice.

Through a qualitative discourse analysis, I examine POLs as events that allow for and invoke this sort of scaffolded identity articulation and development. As students present their work to a public audience their pre-existing, self-defined identity position is dialogically negotiated through engagement with the community and the mediating venue at hand. The POL model serves as an externally authentic cultural tool that allows students a venue to express their perceived identities while the actual performance creates a space of authentic community connections through questioning (Polman, 2010). In both everyday and institutional speech, questioning is one of, if not *the,* central communicative practices in interaction (Tracy & Robles, 2009). Questions in various forms are not simply means of seeking clarification, but rather perform discursive work to direct conversation in a particular direction that provides interlocutors the opportunity to clarify an utterance and repair any uncertain terms. And, importantly, the responses to said questions provide a platform for the speaker to expand upon, clarify and further justify initial claims.

Data and analysis

In this early work, I focus on two vignettes during one day of POLs. The first episode describes a school administrator coaching visiting community panelist on what forms of questioning are appropriate. The second is an account of a tenured student struggling to answer some challenging questions from a staff member who knew them well. In episode one the school administrator coaches:

Nicholas: We'd like your questions to come from a place of genuine curiosity. If you have been in education for a long time, or been in lots of traditional schools you know there's the "guess what's in my head question" that teachers often ask. Our students have lots of experiences with those kinds of schools; it hasn't worked for them. And so they don't work very well here.... You might ask a question like "Shouldn't you pay more attention to your teachers?" That would be like advice giving, not a great question.

He points out that in 'traditional schools' teachers and adults use questions that do not seek authentic or novel responses from interlocutors. These are not genuine information seeking questions, rather they are discursive power plays to limit the range of possible response (Tracy & Robles, 2009). Nicholas makes clear that these students are used to this form of discursive power maneuver and that it does not work for them. The second vignette describes a second year student's presentation with central themes related to her identity as a black woman, transition to adulthood, and concerns of growing up. In the excerpt below she describes a mathematics class focused on personal finance and life choices and subsequently fields questions from a community panelist.;

Beth: Um, my next class I took was Math for Life, and it talks about like what do I need to be successful in life, and like, what I want myself to look like after [school], and I would say this class taught me that I don't wanna grow up, , I won't, I don't know how, It's hard. I would not, nu-uh, I can't

Anna: I think you make jokes and when you are feeling uncomfortable.. So I guess I'm gonna ask you to sit here for a second, cuz I took my time today to be here and I would like to get some thoughts from you about where you are with that. (Beth laughing, begins to whimper)

Beth: And I don't know anymore (wavering voice), I don't know anymore what my passions are....

Anna: And you mentioned social justice, where does that fit in? (Beth, Laughing... "um, alright....")

Beth goes on to describe her interest in criminal justice reform, fitness coaching, artistic expression and explains that she is not so much afraid of 'growing up', as she feels overwhelmed by the choices and commitments she will make in the upcoming years. Without Anna's insistence, Beth would not have articulated these ideas.

Discussion, implications, and areas for future research

Presentations of Learning offer students an avenue for collaborative reflection, identity exploration and the negotiation of positioning/stance that many high school students are not afforded. POLs provided a ritualized, scaffolded environment that appears to invite a synthesis of personal growth and content knowledge that happens through authentic engagement and discourse with peers and community members. Audience panelists challenge students to clearly articulate their claims and can help maintain high standards and accountability. In responding to unanticipated audience questions student presenters are challenged to reconsider, refine and communicate their evolving ideas, commitments, and sense of self.

The preliminary data presented here suggests that the framing and practices of questioning in POLs is of key importance to best solicit student reflection and engagement. The early implications of this work indicate that engaging in the discursive process of questioning as part of presentations of learning affords students a venue to more fully articulate their own agency and identity, as situated in their broader communities of practice.

“You Get to See for Yourself”: Immersive Media to Facilitate Observation and Engagement in Remote Schooling

Eileen McGivney, Harvard University,eileen_mcgivney@g.harvard.edu

Abstract: With protracted school closures forcing young people to learn remotely, schools are in urgent need of innovative approaches that can keep students engaged in their education and support their learning. This poster describes a pilot using Google Cardboard virtual reality viewers and 360-degree videos in remote high school science classes to help motivate and engage students. Early findings from interviews indicate students find them engaging and may be particularly useful for facilitating observational learning.

Introduction

Disruptions to traditional schooling due to COVID-19 are likely to have effects far into the future, including increased high school dropout due to students disengaging from school (McKinsey, 2020). Innovative approaches that create engaging activities and make learning more relevant can be an important strategy for dropout prevention in remote schooling (Kassner et al., 2020). Immersive technology has the potential to increase student engagement, as the sense of “being there” in a virtual space can impact motivation and interest (Dede et al., 2017), including by increasing their focus and attention (Bailenson et al., 2008) and facilitating implicit or observational learning (Slater, 2017). Even short virtual reality (VR) experiences with engaging content may make a difference for students in remote classes that often rely on lectures and static materials, but little is known about their feasibility and effectiveness in this context. Given the myriad distractions young people currently face, and scarcity of engaging and observational learning opportunities, this poster describes a pilot integrating activities that use cardboard VR viewers and 360-degree videos within remote high school engineering classes.

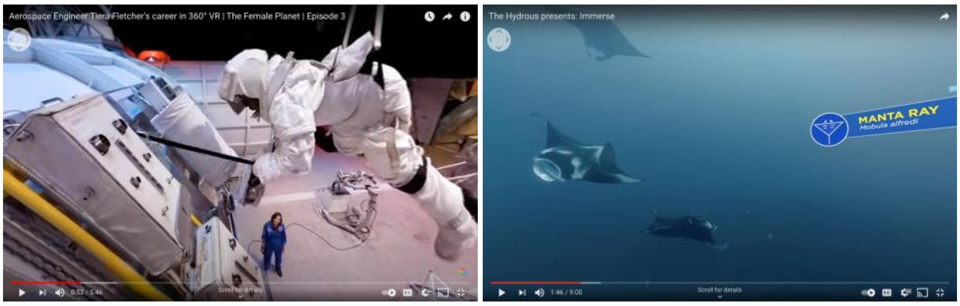

Figure 1: 360 videos used in class. Left: *Aerospace Engineer Tiera Fletcher's Career* (Google). Right: *Immerse: Journey into the Deep Sea* (The Hydrous)

Intervention

This study was conducted in two engineering classes at a public charter high school in a Boston-area midsize city, serving students of whom 100% are eligible for free/reduced-price lunch, 87% are Black or Hispanic, and 13% are English Language Learners. Sixteen of 30 students opted in to the research: seven 12th-grade and nine 11th-grade students, three identify as female and 13 as male. 14 students’ parents, and two students themselves, were born outside the United States. Students are referred to here by pseudonyms.

Initial activities were conducted with five students as one-on-one virtual interviews with the author. Students watched 3-5 videos about structures around the globe related to their engineering projects with a Google Cardboard, and completed pre- and post-surveys and interviews. The second phase consisted of whole-class activities in which all students viewed a 360-video followed by discussions in Zoom breakout rooms. Students participating in the research filled out pre- and post-surveys, and their discussions were recorded and facilitated as focus groups. These activities included a Google video about aerospace engineer Tiera Fletcher and The Hydrous virtual dive about climate change and coral reefs (see Figure 1). The final activity asked students to work in small groups to choose and watch videos together in Zoom breakout rooms.

This poster describes students’ experiences based on interview and focus group data, which were transcribed and analyzed following a flexible thematic coding procedure (Deterding & Waters, 2018). Findings are presented based on the “big picture” themes that emerged from coding by the author and a research assistant.

Student experiences in remote school: “Harder to learn”

Students discussed it being “harder to learn” (Maya) remotely, particularly concepts or subjects they find difficult, where they need to go in-depth, or when material is fast-paced. Students attributed this difficulty to a lack of time with teachers and peers, as well as feeling unmotivated. As Diana put it: "I just feel that [online learning] makes me unmotivated. I don't want to do it, but I just have to." They attributed lack of motivation in part to materials, media, and technology in their remote class activities. For instance, Nora said videos and other materials used are not interesting, and "I don't want to do work at home, I want to watch YouTube, so I am very distracted." Maya said she finds online classes lacking because she is a "hands-on, visual learner." Jack described how he missed "the environment" of being in school, and he is discouraged: "I put in a lot, [but] learn less."

360-degree videos are "more engaging" and facilitate observation

Most students described the videos as *engaging*, demanding focus because "you can't take your eyes off of it…you have to give your complete attention to it" (Diana) and "because it's everywhere, it's all you can see" (Nora). Others described it feeling more "interactive," because "you can control it, and there's multiple stuff to look at" (Matthew) and "I can look at what I want to" (Logan). They also found the videos engaging as they related to their interests in travel, careers in engineering, and the environment. Even despite not being very passionate about climate change, Logan said, "I was surprised at how engaged I was" by the beauty of the virtual dive. This may indicate potential for VR to leverage students' intrinsic motivation if they tie course content to students' interests and help develop new interests. It is important to note students also discussed the limitations of the media. Students who had tried other VR equipment noted it would feel more immersive if it was a higher quality and more interactive. Others were uncomfortable holding their phones, and felt dizzy or motion sickness.

A theme that emerged from interviews is that students described the benefit of immersive videos as being able to more deeply observe than they have the opportunity to do in other online class activities. Logan felt this through increased agency, "I found it more interesting to be able to look around and look at specific things I want to look at." Nora described this in contrast to more typical instruction: "You just kind of follow them around andjust observe… instead of talking at you, you get to see for yourself."

This deeper observation may help students learn about places and phenomena in a way that is particularly difficult in remote schooling. Logan described the virtual dive as very useful to show "how beautiful the ocean looked…during the pandemic VR gives us—closer to reality, to a more interactive experience." And for Maya it made her feel "okay with the quarantine… especially now that we can't [travel], this is like the next best thing." The ability to look around freely and at different angles also made it easier for them to understand the environment.

Conclusions

This small pilot points to interesting findings to inform future work. First, students are clearly struggling with remote schooling, and they feel their learning is suffering. Given the likelihood that this and many other schools will remain online for the foreseeable future, schools urgently need to find solutions to support them, to increase their engagement, and help make learning easier. While the intervention described here, utilizing immersive videos and cardboard headsets, will not address many of the students' challenges, the pilot suggests they may be helpful in engaging students and giving them a different way to work with curricular materials.

Abstract: Students in science education struggle with creating and iteratively revising models based on evidence. We report on an implementation of a "gallery walk" activity where 5th grade students used the Model and Evidence Mapping Environment (MEME) software tool to develop and then critique each other's models of an algal bloom. MEME was designed to support students in creating visual models organized around the components and mechanisms of the target phenomena, linking evidence to those models, and then providing and responding to comments on the specific features of the model. Findings illustrate how this was a productive environment for students to make their ideas about modeling criteria visible, and how their ideas cut across normative dimensions of modeling expertise.

Keywords: modeling, science education, complex systems, peer critique

Objectives or purposes

Modeling is a core practice across scientific domains, and thus an important practice for students to learn (NRC, 2013). Scientists create models of phenomena based on the evidence they currently have, and iteratively refine these models in response to feedback and new evidence (Pierson, Clark, & Sherard, 2017; Schwarz, Reiser, Davis, Kenyon, et al., 2009). Thus, helping students learn how to engage in modeling practices necessarily means helping them understand the epistemic elements of this practice, including the value of continuously refining models of a phenomenon to reflect new evidence (Duncan, Chinn, & Barzilai, 2018). The Scaffolding Explanations and Epistemic Development for Systems (SEEDS) Project aims to understand how fifth grade students engage with evidence as they explore a phenomenon (algal blooms) through modeling. To support this modeling practice, we developed the Model and Evidence Mapping Environment (MEME): a software tool that helps students create a simple visual model, view new evidence of the phenomena being studied, iteratively refine their model in response to the evidence, and explicitly link evidence to the model to help indicate how the features of their model are supported by the available evidence (see Figure 1). To help students reflect upon and revise their models, MEME also includes a "comment" function that the teacher and other students can use to offer feedback on specific aspects of the model. The current paper reports on the implementation of a "gallery walk" activity in which students offered feedback on two of their peers' models, then responded to their peers' feedback. This activity was intended to help students identify opportunities for improving their models, and to help make students ideas about modeling and its' relationship to evidence public for discussion and reflection.

Methods

The gallery walk was a single activity incorporated into a five-week long unit with a grade five classroom of 20 students (of which 15 boys and 4 girls consented to participate in the research) at a public elementary school in the American Midwest. The students worked in dyads throughout most of the unit with each dyad assigned a computer to access MEME. During the unit, students were introduced to modeling, presented with the phenomenon of interest (green "stuff" on a pond leading to fish dying), and provided access within MEME to research reports and computer simulations to use as evidence while iteratively updating their own models. New evidence was introduced and explored each session, with students encouraged to revise their models as they uncovered new ideas. After 10 sessions, the students participated in the gallery walk. All sessions were video recorded.

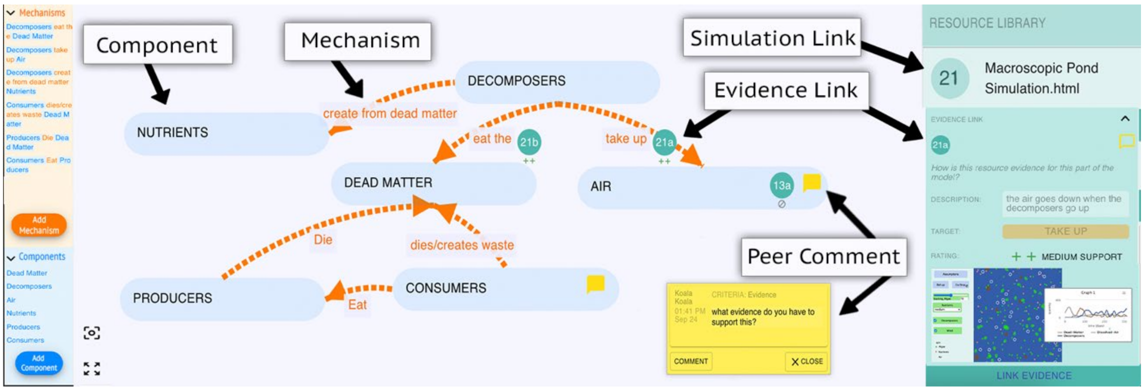

Figure 1. A student groups' model, with an open comment that asks what evidence the authors had to support their choice, a common question when students were unclear about an element, or thought it was incorrect

Results

Our analysis of students' interactions with MEME re-enforce the evidence that 5th grade students can engage in productive model critique sessions, particularly when organized around a "gallery walk" model and shared collective criteria. Furthermore, they shed light on students' negotiation and understanding of good modeling practices, and the role of evidence in these practices. Notably, students appear to focus first on obvious gaps in the model (e.g., a missing mechanism connecting a component to the rest of the model), or missing evidence. However, with the help of MEME, students did look for evidence to support their peer's models, and even discussed whether the evidence they had available to them supported or contradicted the model in clear ways. While our long-term hope is that students will focus primarily on these more nuanced evidentiary standards, we also recognize that it is hard to evaluate a model that doesn't make sense to the viewer. Thus, this apparent sequence of moving from seemingly superficial comments to more nuanced critique is quite intuitive, and future work would benefit from engaging both levels as those seemingly superficial levels are in fact necessary groundwork for the more robust sensemaking.

Computational Art Practice in Transdisciplinary Contexts

Gabriella Anton, Northwestern University, gabriella.anton@u.northwestern.edu
Kit Martin, Northwestern University, kitmartin@u.northwestern.edu

Abstract: Leveraging Dewey's vision of learning as an aesthetic experience, we join other contemporary scholars in arguing for transdisciplinary approaches to STEM education that harness computational thinking and art. We present a transdisciplinary STEM context: a game design course, Modeling Time, focused on supporting students' exploration of history. We use a mixed-methods approach to capture the ways students create and share computational and art knowledge with peers. This work contributes to understanding computational art practices.

Introduction

Computational thinking (CT) education has largely focused on integration within computer science (CS) and, more recently, in science, technology, engineering, and mathematics (STEM) (Grover & Pea, 2013; Weintrop et al., 2016). We seek to broaden this perspective, drawing upon Dewey's vision of learning as an aesthetic experience (Dewey, 1934) to argue that these computational practices should not be siloed within one field. Proponents of transdisciplinary education in STEM argue for the importance of bringing art together with STEM disciplines (Sengupta et al., 2019; Kafai, Proctor, Lui, 2019). For these contemporary scholars, art is not simply a context for STEM integration. Instead, art fundamentally shapes the experience of STEM in a way similar to Dewey's notion of aesthetic experience (1934). Within education, efforts to combine CT, art, and STEM have been shown to be successful in engaging children's deep thinking while sparking creative epistemologies (Sendova & Grkovska, 2005; Turkle & Papert, 1990). In this paper, we respond to this call with the design of a computational learning environment at the intersection of history, art, and STEM, or game design more specifically. We build on the successes of other scholars who designed and implemented game design environments to support computational thinking and creative practices in learners. We also add a historical layer to game design. In this paper, we explore the ways that students gained, shared, and co-created knowledge related to their computational art practices. More specifically, we ask: How do students collectively explore and share computational art practices within a STEM context?

Methods

We explore this intersection of art and computational thinking through the context of a game design course called Modeling Time, which took place during a weekend enrichment program in a Midwestern city in the US. The course totaled 10 educational hours. In this course, eight 5th grade students learned how to create 2D and 3D game environments using the Unity game engine. Both authors designed and co-taught the course. More information about the design, educational scaffolding, and student artifacts can be found in the authors' prior work (Martin & Anton, 2018). Seven students, ranging from 10-11 years old, participated in the research study (4 F, 3M). For this paper, researchers analyzed 5.5 hours of video of the class while the students were working in a large group with computational tools. We coded the data with themes and practices related to sharing knowledge and critiquing design found in literature on practices of art spaces (Becker, 2008). The finalized coding scheme captures the four codes: *showcasing* (a student showing others their work), *auditory reaction* (a student vocalizing a reaction to their design without response from others), *peer help seeking* (a student asking another student a question), and *facilitator prompted design* (facilitators providing support or help without prompting).

Findings

A total of 99 episodes were identified across the 5.5 hours of video analyzed. The total counts for each code are as follows: *showcasing,* 37; *auditory reaction,* 35; *peer help seeking,* 21; and *facilitator prompted design,* 23. We graphed these codes to show their occurrence over time (in minutes) (see Figure 1). This graph shows that there were more episodes of *facilitator prompted design* during the first day. The students were more expressive about their designs starting near the end of the first day and continuing throughout the second day. We observed higher occurrences of *showcasing*, *auditory reaction*, and *peer help seeking* during these periods, especially during the second day. There were more coded events, and higher occurrences of these student-initiated events (*peer help seeking*, *auditory exclamations*, and *showcasing*) on Sunday compared to Saturday.

There are several explanations for why we might observe these differences across the two days of the course. From a social perspective, students got to know each other over two days, so we would expect to see more social behavior emerging as they spent more time together and became more comfortable with each other.

Qualitatively exploring the coded episodes, we found that on the first day, students more often showcased their work to facilitators; students would raise their hands to show off progress or make comments as the facilitators walked past them in the room. This pattern aligns with the social hypothesis that students may not have felt as confident to share with peers.

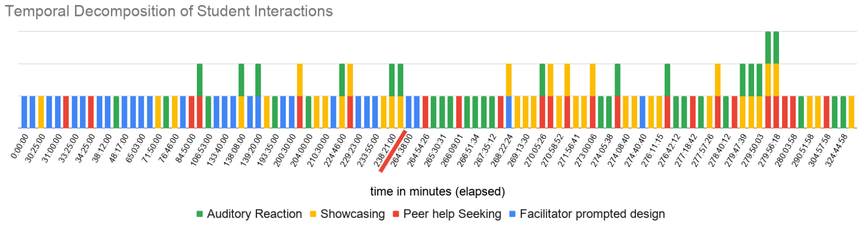

Figure 1. Temporal decomposition capturing the temporal pattern of codes across the course.

Looking more closely at the data, we began to see that these patterns of limited social engagement with peers also aligned with the times when students were exploring 2D game environments. During the end of the first day, we introduced layering 3D elements within the 2D spaces to create depth within their platformer games (specifically at 1:36:20 minutes). After this was introduced, students began to showcase with more frequency to peers. On the second day, we observed that students showcased to peers throughout the entirety of the day. Moreover, they began to engage in help seeking from peers, suggesting emergent perceived expertise. These moments of help seeking encapsulated both computational questions (e.g., “Ice? Where do you have ice? How do you do it? Show it to me”) as well as artistic or design questions (e.g., “Should I get a snow mountain?”, “Does the desert have a lot of trees?”). This shift may relate to a deeper connection with the 3D medium compared to 2D. When asked if anyone had experience with 2D platformer games, only one student indicated they had played a 2D platformer game. When asked about 3D games, all students indicated at least some experience with 3D games, and several compared it to popular sandbox videogames.

Discussion and conclusion

We explored the role that students take in creating and sharing computational art practices within a transdisciplinary STEM course. We found that students, if interested and inspired, are vocal in reacting to their designs and seek to share their achievements with others, particularly peers. This work reflects the outcome of a small group of students over a short period of time. As such, these patterns of engagement may not appear in larger, more traditional courses. We seek to explore how this work translates into formal classrooms to further support sustainable efforts in transdisciplinary computational art practices. Additionally, future work will explore the deeper interactions between learners. The success of this course design in sparking the interest and computational artistic practices in learners suggests the utility of this type of transdisciplinary, aesthetic STEM learning experience.

Constructivist Dialogue Mapping: A Comparison of Museum Experience

Kit Martin, Michael Horn, Uri Wilensky
kitmartin@u.northwestern.edu, michael-horn@northwestern.edu, uri@northwestern.edu
Northwestern University

Abstract: We employ constructivist dialogue mapping to provide a comparison between the learning experience in a traditional museum exhibit, and the experience while using an agent-based modeling game built for learning in a museum. This paper serves as an example of the power of CDM to track the results of turning knowledge authoring over to the visitors.

Key Words: Museums, Evaluation, Agent-Based Models, Ants, Complexity, Constructivist Dialogue Mapping, Elaboration as Learning

Introduction

Since Leinhardt and Crowley (Leinhardt et al., 2003; Leinhardt & Crowley, 1998) presented their vision for studying elaboration as learning, museum studies has been looking for a way to operationalize studying elaboration. The framework makes it clear that it is essential to attend to the richness of visitor conversation around an exhibit. In this paper we offer a tenable means to track these elaborations using constructivist dialogue mapping (CDM) (Martin et al., 2020) and use it to compare between two museum experiences. Using CDM, we operationalize Leinhardt and Crowley's vision to present findings from exhibits that show divergent interaction types: deep behavior observation and wide recognition. Thomas Humphrey and colleagues argue that hands-on interaction with science museum exhibits is not the same as active, prolonged engagement (Humphrey & Gutwill, 2005). They argue that designers should look beyond attracting and initially engaging visitors to focus more on creating situations that invite prolonged exploration. *Learning Conversations in Museums* (Leinhardt et al., 2003) proposed a means to study how learning actually occurs in museums. The authors' work in museum learning addresses and attempts to solve a core issue: what constitutes learning in museum research, and specifically, what terms or actions do we track in order to measure it. From these problems, the authors propose three outcomes, the last of which is important for CDM. They argue that their approach provides a novel, stable, and distributable methodology to conceptualize, collect, and analyze conversations as a process and as an outcome of learning in the museum context. The qualitative method we use in this study, CDM, has the same aim and could solve core operations issues with the original framework, which we will demonstrate in this paper.

Methods

In this paper we compare the outcomes of the two exhibits using constructivist dialogue mapping (Martin, et al., 2020). Using conversational elaboration measured through CDM, we present the analytical result of the experience of a traditional exhibit and compare it to the result from a game-based exhibit. The game, Ant Adaptation, was designed to afford participants agency in authoring their experience. One hundred fifty participants played the game in the museum, and six participants walked through the traditional exhibit. We recorded all the interactions. We recruited participants as they approached the exhibits. we asked participants for permission to conduct a pre-interview. The three participants featured in this report were white women aged 30, 40, and 22. They were selected to make the samples more comparable. When patrons played the game, they walked up to it and interacted with it. We collected pre- and post-interviews, as well as recorded audio of their interaction. We then transcribed these recordings for a total of 150 interactions.

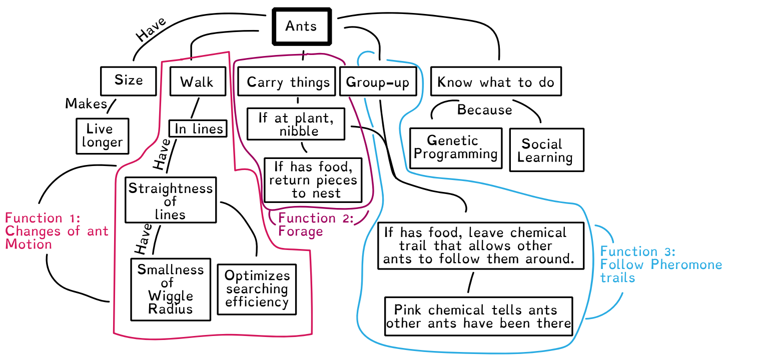

Figure 1. Change of ant motion, foraging, and pheromone trails explains how ants explore space.

Findings

We found participants name more total items in the traditional museum experience — wide recognition — but they elaborate more on items when using the dynamic agent-based model — deep behavior observation. Groups in the traditional exhibit referenced far more items during their visit. To demonstrate the differences in elaborations, we present an example of each exhibit below.

Marcia engages in deep behavior observation during a one-hour interaction with the game, Ant Adaptation. Marcia learned that size does not negatively affect an ant's chance to reproduce. But what led to her discovery was more complex: she first had to learn that an ant colony is a complex system where only the queen reproduces, and all the individual insects work towards that collective's betterment. At the beginning of the interview, she made basic observations about ants. When the interviewer asked if she'd ever noticed anything about ants she said "Yeah, they walk around and sometimes they appear in big groups walking around and sometimes they carry things from place to place. Like food stuff, and house building materials."

While playing, as shown in Figure 1, she ideates three functions: (1) 'Changes of Ant Motion', (2) 'Forage', and (3) 'Lay Pheromone Trails'. They are labelled in red, magenta, and blue, respectively. Extrapolating on these functions, she attains her big learning moment: that more, small ants collect more food faster and, therefore, "Smaller ants will reproduce at a faster rate." This implies a systems-understanding of how food flows into the colony.

We juxtapose this deep elaboration with the much wider, shallower elaboration afforded by the traditional exhibit. Two women—a mother and a daughter—attend an exhibit about biodiversity. During the pre-interview they named only one first order item, and two elaborations that expand its meaning: "Specimens (are) pieces of the natural world (that are) studied." While they walk through the exhibit, they elaborate on the items they notice but offer almost no behavioral elaboration. As shown in Figure 2, as they walk through, they mention a turtle they are looking at and take note of its aesthetic. They notice a bear brain that is "not very big", and gar, which the daughter hates. They note a pit viper would have made "Indian Jones unhappy", and that the tube worm is "gross and creepy". Notably, there is very little elaboration: of the 28 items they notice while walking through, they offer 18 elaborations, with an average elaboration of less than 1 per item. The elaborations they offer are surface level, such as "really pretty," "hates them," or "not very big." These are in contrast to the elaborations of functions noted while playing the game. After attending the traditional exhibit, during the post-interview, the two only mention six total items.

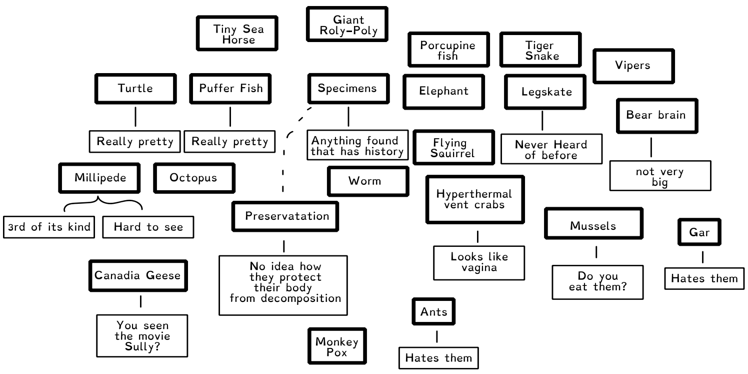

Figure 2. What was noticed during the biodiversity exhibit.

Conclusion

We seek to gain a better understanding of how constructivist dialogue mapping can help researchers understand how learners elaborate on their understanding, both in dynamics of systems and more traditional museum exhibits. In this paper, we saw two different types of learning unfold: (1) wide recognition and (2) deep behavior observation. In the biodiversity exhibit, we saw participants name a wide range of ontological items they noticed as they walked through. In contrast, while playing Ant Adaptation, participants deeply elaborated on the behavior of fewer ontological items. This paper has shown that CDM can demonstrate learning as elaboration, operationalizing Crowley and Leinhardt's earlier work. As seen through using CDM, we demonstrate that we can evaluate the design of museum exhibits and their impact on the type of learning the exhibit affords.

Development of a Faculty Community of Practice for Scholarship of Teaching and Learning

Jonan Phillip Donaldson, Ciana Bowhay, Kathrin Dunlap, Merlyn Joseph, Mahjabin Chowdhury
jonandonaldson@tamu.edu, cianamarie@tamu.edu, kdunlap@tamu.edu, joseph@tamu.edu, mahjabin@tamu.edu
Texas A and M University

Abstract: Long-term sustainability of high-impact pedagogical practices following faculty development is often difficult. Thus, a multidisciplinary community of scholars, the Innovation and Design for Exploration and Analysis in Teaching Excellence (IDEATE) community, was created. The IDEATE model is grounded in learning sciences, complex conceptual systems, situated learning theory, and design-based research to enable faculty to implement transformative practices, evaluate impact, and iteratively improve learning designs. Scholars participated in interviews regarding teaching and learning, attended learning sciences workshops, generated collaborative artifacts, and developed scholarship of teaching and learning (SoTL) projects. Preliminary analysis suggests changes in practice and understanding of relevant learning theories. Design moves for the second iteration will be discussed.

Background

The purpose of this study is to develop theoretical and practical knowledge regarding the design, implementation, iteration, and impact of this innovative model for conducting Scholarship of Teaching and Learning (SoTL) through the development, support, and long-term sustainability of a community of scholars. The participants, who are also core members of the community, will engage in SoTL studies using the theoretical and methodological framework co-developed by the researchers and the community.

Methodology

This design-based research (DBR) project (Barab & Squire, 2004) involved aspects of case study, grounded theory, and complex systems analysis methodologies. As a DBR study, the primary inquiry is the efficacy of the program design over multiple iterations. The first iteration has been completed, and data analysis is currently underway. Our initial step was the creation of the Innovation and Design for Exploration and Analysis in Teaching Excellence (IDEATE) model for the development, support, and long-term sustainability of a community of practice with strong theoretical grounding and shared practices in SoTL. The first core element of the IDEATE model is grounded in situated learning theory, which defines learning as increasing identification with, and engaging in the practices of a community (Lave & Wenger, 1991). The second core element is grounded in complex conceptual systems theory, in which practices in teaching and learning are identified as emergent in conceptualizations of learning (Donaldson, 2019). The third core element is the use of Design-Based Research (DBR) methodology for all studies conducted by the community in classroom contexts (Barab & Squire, 2004; Sandoval & Bell, 2004). The fourth and final core element in the IDEATE model is the adoption of definitions of learning prominent in the learning sciences, including conceptualization of learning as: 1) construction of knowledge and artifacts, 2) as becoming, and 3) as enactive, embodied, embedded, and extended (Donaldson & Allen-Handy, 2019; Steier et al., 2019). The IDEATE model also integrates additional learning sciences theories, including identity theories, constructionist learning (Kafai, 2006), cultural-historical activity theory (Greeno & Engeström, 2014), and 4E cognition theories (Steier et al., 2019). This IDEATE model is visualized in Figure 1 in which the center squares represent the four grounding frameworks, and the outside circles represent design principles. Participants in the initial iteration of the program are 10 academic professional track (APT) faculty and one tenured faculty from various disciplines and departments at a large R1 university in the Southern United States. Before participating in the IDEATE program, community members engaged in semi-structured, in-depth interviews about their current beliefs and practices regarding teaching and learning. As research participants in this study, the community members participated in regularly scheduled, bi-weekly activities and collaborated to produce artifacts such as a community philosophy statement, vision statement, and goals statements. Also, as part of the program activities, each participant produced bi-weekly reflection papers. Semantic network analysis is being used to develop network maps of interacting and interdependent ideas in the complex conceptual systems. Prior to beginning the second iteration of the IDEATE program, data was analyzed for evidence of strengths and weaknesses in design features and the findings have been translated into design moves to inform the next iterations (Barab & Squire, 2004) of the IDEATE program as it expands into a larger group of faculty participants. This

Second phase of the IDEATE program will grow the community of scholars from the initial “core” to a larger self-sustaining community.

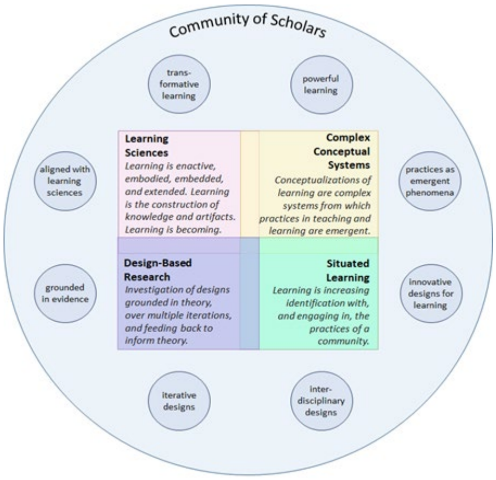

Figure 1. The IDEATE Model.

Preliminary findings

Preliminary findings regarding the community formation suggests that conceptualizations of learning have shifted. The community was highly generative, including creation of robust community documents, and developed three fully-formed SoTL research projects and secured IRB approval. Preliminary findings have been translated into a set of design moves that are being implemented in the second iteration. The first change is in workshop scheduling. In the second iteration of this program, learning for the community (theory and research methodology) will be further integrated with practical application in ongoing SoTL research projects. Transformation of the multidisciplinary community (current form) into an interdisciplinary community is an additional goal of the second iteration. To accomplish this, we are recruiting new members to introduce ideas, technologies, or methodologies from their own disciplines to the broader IDEATE community which could potentially inform new areas of research in teaching and learning.

Significance and discussion

The purpose of this model is to enable faculty to take charge of the implementation of innovative and transformative practices in teaching and learning in a substantive way. This study will add to knowledge regarding scholarship of teaching and learning practices, particularly in the innovative approach of developing a community of scholars around the clearly defined, evidence-based IDEATE model. This study will also provide empirical evidence regarding the impact of addressing conceptualizations of learning as complex conceptual systems from which practices in teaching and learning are emergent. Finally, SoTL projects being investigated by the core community members will result in subsequent publications that will further inform the field of SoTL.

Abstract: Scholars have called for *equity-oriented, community-centered approaches* to STEM-related research and design to help address the persistent disparities and inequities in these fields. In response to this need, we explore a *community-driven design research* approach, a collaborative research process in which Indigenous partners maintain sovereignty. As a team of Indigenous and non-Indigenous educators, researchers, and designers, we present our thinking-in-progress of how we have engaged the initial phases of our community-driven research and endured in the midst of global pandemic and unrest in 2020. Findings capture a snapshot of our ongoing insights for effective strategies to engage and sustain community-driven design research as a critical methodological approach.

Introduction

Leaders in informal science education have argued for *equity-oriented, community-centered* approaches to STEM-related research, design, and practice and called for a recognition of the broad and diverse cultural, historical, and political roots of research, science, and technology (Bevan, Barton, & Garibay, 2018). One persistent challenge to broadening participation in this way is that many efforts operate from the assumption that science and research are acultural and apolitical, which results in a deep epistemological tension to *how* (Bang & Medin, 2010; Johnson, 2018; Morales-Doyle, Vossoughi, Vakil, & Bang, 2020). As a team of Indigenous and non-Indigenous educators, researchers, designers, and community members, we take a *community-driven design research* approach, a collaborative design process in which Indigenous partners maintain sovereignty as designers, to our partnership work. In this paper, we share the initial phases of our community-driven design research approach with the shared goal of preserving and sharing the culture of the Northwestern Band of the Shoshone Nation (NWBSN). In particular, we focus and reflect here on how our community-driven work endured and continues to endure both the coronavirus pandemic (i.e. COVID-19) and the global reckoning with racial injustice. We are guided by the following research question: *What are effective strategies and processes for sustaining community-driven design research in 2020?* We present a collective reflection on how our work together has been shaped by the catastrophic events of 2020.

Methods

Our community-driven process is heavily informed by TribalCrit Theory's (Brayboy, 2005) three key principles for partnering with tribal communities: respect and reciprocity in relationships, self-determination, and sovereignty. Our community-driven process is also shaped by community-based design research (CBDR; Bang et al., 2016) approach. This methodological orientation recognizes the historical, cultural, and political nature of partnering with Indigenous communities. We are collectively engaged in a five-year critical ethnographic (Madison, 2011) study. Data include: *fieldnotes* that are collaboratively written every week, *partnership-building artifacts* such as meeting agendas or resources shared, and *in-depth interviews* with the project team. We understand our design process as an intrinsic case (Stake, 2008), which has the purpose of understanding the case itself. We employed a collaborative and reflexive meaning-making analytic approach to construct cases. We collaboratively triangulated interpretations and claims across partners, perspectives, and documentation. Tribal partners' (Author 2, 3, 4 & 5) analytic insights are integrated in this work as transcriptions of data analysis meetings. University-affiliated drafted a re-telling of our collective insights and Tribal Elders reviewed the manuscript and these re-tellings prior to submission.

Insights & Implications

The simple practice of *gathering* was an act of resistance to the isolation the pandemic has brought. Every week we come together as a whole. This showing up, even in the virtual world, is something we attribute to our persisting together as a collective through serious personal challenges and unanticipated project roadblocks. Here are five practices we employed in our gatherings that helped us endure:

Building a collective foundation and vision together. We completed research ethics training, a cultural competence course, and mapping our shared values and goals. Gwen Davis, NWBSN Tribal Elder explains, “I’ve never been part of the ground work like this before. It makes me feel young! It is such an energy…you know, somebody asking you what your opinion is.” Gwen further expounds that this foundation allowed us “to express ourselves [and made] our group stronger.”

Staying flexible and open to new possibilities. Zoom afforded connections amongst the team and, even more significantly, between tribal elders and youth in new ways and across previous geographical constraints. Gwen reflects, “Learning how to Zoom…this is a whole new brand new area, you know, having to speak and talk on a computer.” From these new kinds of connections, a need emerged for a youth coordinator, Monica Smiley, NWBSN Tribal Member. She shares her experience with this practice, “Everyone has a flexible schedule and someone is always available…having this support there is really good like a support system.”

Reflexivity and responsivity. Our weekly gathering became a safe space for reflection and iteration. Patty Timbimboo-Madsen, NWBSN Tribal Elder, highlights, “Because it is research, you know, we have the ability to change...to step back and look at it and review it again to see if we can come up with a better way...”

Adapting technology. Rios Pacheco, NWBSN Tribal Elder, shares “Now we're using the technology and people like what we're doing and we're still sharing our traditions. But what we don't visualize is that other people are tuning into those and now they're generating more information than if we could just talk to them…so it's really helping a lot to share our culture and share the ideas…the stories so that way more people can understand the culture that we have.”

Humor. Put simply, we laugh together. This, for us, is a sign of deepening trust in our relationships.

In our work, we join scholars who came before us (e.g., Bang & Medin, 2010; Johnson, 2018; Morales-Doyle, Vossoughi, Vakil, & Bang, 2020) and argued for a fundamental shift in what it means to conduct research and do science. Our insights build on and contribute to existing work exploring and defining community-based and design-based methodologies (e.g., Bang et al., 2016). We posit that, now more than ever, we must humanize our research methodologies not only for positive community impact, but also to decenter harmful and marginalizing notions of what it means to do research.

Implicating Practice: Using Rehearsals to Move Toward Equitable Science Teaching

Sara Dozier, Stanford University, dozier@stanford.edu
Lynne Zummo, University of Utah, lynne.zummo@utah.edu

Abstract: Student-centered discourse is a key component of "ambitious" science teaching practices in which teachers facilitate discussion that engages students in scientific practices to understand scientific concepts. Simultaneously, teachers must create learning environments that counteract inequities along intersecting axes of identity. But how do teachers learn teaching practices that both support student sensemaking via discourse and respond to issues of equity? We examine one method of in-service teacher learning: rehearsals, or approximations of practice. Building on emerging evidence from prior research, we explore the role of rehearsals in developing secondary science teachers' adaptive expertise in facilitating equitable productive discussion. We analyze data from 17 "debrief" discussions that followed rehearsals, asking how shared knowledge 1) develops around discourse-centered science teaching and equity, and 2) is deployed in teachers' adaptive expertise as they reconsider past practice. Preliminary results reveal the possibility of rehearsals and also highlight the need for clear supports.

Introduction

There have been many calls for science learning experiences to be grounded in student-centered discourse (e.g. Kelly & Chen, 1999). Using "ambitious science teaching" practices, teachers are expected to facilitate productive discussions through which students come to have a stronger understanding of science concepts and increase their capacity for engaging in scientific practices (Windschitl, Thompson, & Braaten, 2020). At the same time, we acknowledge the unequal and unfair landscape of science classrooms; inequities related to marginalization along multiple and intersecting axes of identity, such as ethnicity, race, home language, SES, and others abound (Bang, M. et al., 2012). More and more calls for equity in education put the onus on teachers to counteract these historic inequities (Cochran-Smith et al., 2016). To support teachers in both of these efforts, innovative professional learning practices are needed. Rehearsals are a high-leverage, high-impact, and low-cost practice that show promise for supporting teachers in pursuing ambitious teaching practices and creating more equitable learning spaces (Kavanagh et al., 2020).

Facilitating productive discussion remains a challenging pedagogical practice, as it is a type of practice that demands adaptive expertise, or the expert performance of complex professional practices that shift in response to the contexts of their use (Kavanagh et al., 2020). Baldinger and Munson (2020) hypothesized that rehearsals could be valuable in developing adaptive expertise not only for the teacher doing the rehearsing but also for teachers participating as learners. In this study, we aim to clarify the explanatory power and extent of Baldinger and Munson's model as applied to science teacher learning and also to propose potential extensions an adaptations.

Methods

This study analyzed video recordings of rehearsal debriefs by in-service secondary science teachers in a professional learning experience (PLE) in the United States. Using a qualitative coding framework that integrated *a priori* codes from Baldinger and Munson (2020) with emergent codes, we examined rehearsal debriefs by 17 science teachers, who taught at 15 different schools serving historically marginalized student populations. Each teacher assumed the role of rehearsing teacher (RT) during a 12-minute rehearsal oriented around a discussion-based learning activity, while the 16 non-rehearsing teachers (NRT) participated as students. The authors were the facilitators of this PLE, and we facilitated a 5-minute debrief.

Drawing on teacher noticing research as an analytic framework, we use concepts established in noticing literature, such as attending, interpreting, and implicating (Sherin & Van Es, 2005) to characterize what participants noticed from the rehearsal and then brought into the social space of the debrief for further deconstruction by teachers. We see the moments that participants attended to, surfaced, and made meaning from socially in the debrief as important to understanding the affordances and constraints of rehearsals for the development of adaptive expertise around equitable science teaching. In an iterative process of analysis, we watched video recordings of each debrief discussion, wrote analytic memos, and discussed our interpretations. We then transcribed the debrief videos and applied coding frameworks from Baldinger and Munson (2020) integrated with emergent codes, using utterances as the unit of analysis. Our coding scheme is shown in Table 1.

Table 1: Coding scheme applied to transcripts of rehearsal debriefs

	Code: Definition
Noticing	**Attending:** Statements or description of observable events from the rehearsal
	Interpreting: Statements that assign meaning or analyze an event from the rehearsal
	Implicating: Statements that suggest revisions or how events could have gone differently
Focus of Noticing	**Students:** Noticing (attending, interpreting, or implicating) about students or student thinking
	Practice: Noticing about a specific teaching practice, move, or strategy used during the rehearsal
	Content: Noticing about the disciplinary content of a rehearsal
Position	**Student:** NRT speaks from position of the student or learner
	Teacher: NRT speaks from position of the teacher
Attention to Equity	**Equity:** Any attention to equity within a noticing, including references to specific strategies learned in the PLE to support equity

Findings

Our initial analysis has identified preliminary findings that converge around three broad themes. First, the vast majority of NRTs' noticings utterances were either attending or interpreting, with few instances of implicating, the key type of noticing that can lay the groundwork for growth in adaptive expertise. We suggest that the low frequency of implicating observed here is likely related to the structure through which NRTs were accustomed to giving feedback, which did not create adequate opportunity for implicating. As a result of this protocol, much of the implicating, an important act to support teacher learning via rehearsals, was done in the final phase of the debrief where the RT responds to the comments of the NRTs.

Where we did identify acts of implicating, we saw significant possibility for the development of adaptive expertise. In their acts of implicating, RTs built off of the NRTs' comments that were noticing and interpreting their experience from a student's perspective. RTs used that information to consider revisions for future lessons. Another trend was that ideas and issues of equity were often implicit and emerged through common language used in the PLE. For example, across the PLE, there is emphasis on "equity of voice," or a principle that emphasizes the importance of all students having equitable opportunities to speak and be heard in the classroom. NRTs often referenced "equity of voice" in noticing aspects of rehearsals. We also identified moments in which inequity was implicit, such as in emphases on "academic language." Overall, equity did not figure strongly in the debriefs, despite the PLE having an explicit focus on equity.

Implications

These findings indicate that rehearsals are useful and beneficial for both rehearsing and non-rehearsing teachers. However, structures for providing feedback affect both the content and quality of the debrief discussion. Prompts or feedback protocols that support NRTs in being explicit about whether feedback is attending, interpreting, or implicating may help them analyze and learn from rehearsals. In particular, teachers need increased support around implicating, including examples, prompts, and reflection about how to provide this type of feedback. Finally, structures that support noticings related to equity are especially crucial if teachers are to engage in implicating and increase their adaptive expertise around issues of equity.

MineArt: Active Prolonged Engagement through Participatory Exhibits in Art Museums

Lexie Zhao, Michael Horn
Xinyuezhao2020@u.northwestern.edu, michael-horn@northwestern.edu
Northwestern University

Abstract: Learning in museums has increasingly come to be characterized in terms of participatory and active engagement on the part of visitors. In this poster, we present a design prototype for an interactive art museum exhibit called MineArt. This exhibit allows visitors to create art pieces through modifications of famous artworks with folded notes as scaffolding and a postcard wall for critique and engagement. In this work, we hope to facilitate the meaning-making process of art by creating exhibits that incorporate audience participation and APE (active prolonged engagement).

Introduction

Museums can be described as public institutions of learning—places that people seek out to satisfy their curiosity and to learn more about their worlds. Museum learning is a subset of a larger, ever-evolving continuum of learning and meaning-making across the life span (Falk & Dierking, 2000). Recent trends in participatory museum learning have invited people to create, share, and connect around content and exhibits. Particularly for cultural institutions with a mandate to use their collections for the public good, digitization, and accessibility of content have become a top priority (Simon, 2010). In recent decades, a broad range of digital technologies and devices have been introduced into interpretive encounters with art in museums (Garmil, 1997; Witcomb, 1997) with visitors accessing and producing interpretations across different types of interfaces, platforms, and devices (Steier, et al., 2015).

As a result, we have seen more participatory exhibits emerge from art museums. The Denver Art Museum (DAM) provided a constrained participatory museum experience in their *Side Trip* gallery on display in 2009. Visitors can make their rock music posters with provided materials (Simon, 2020). However, *Side Trip* focuses on the creation instead of understanding and interpretation of existing posters. De Youngsters Studio encourages children to explore art fundamentals through hands-on activities and visual technology (De Youngsters Studio, 2020). However, users explore the fundamental elements of art out of the context of specific artworks.

Inspired by this prior work, we are designing an art learning exhibit called MineArt that we intend to enhance the meaning-making process through personal interpretation and APE (Humphrey & Gutwill, 2005). An APE exhibit aims to foster visitor behavior that includes questioning, exploratory activity, observation, collaborating with other visitors, and searching for and reflecting upon causal explanations for exhibit phenomena (Humphrey & Gutwill, 2005).

Our goal is to enable learners at art museums to 1) appreciate and curate art pieces through modifications of colors and textures on famous artworks; 2) formulate their interpretations through reading the folded; 3) deepen engagement through discussing, critiquing, and taking home a postcard of other visitors' artworks in front of a postcard wall. To sum up, MineArt provides art knowledge in an intriguing and open-ended format while maintaining a free-choice learning environment (Falk & Dierking, 2000) for users to curate and critique as they see fit.

Design principles

In this exhibit, users can change colors and strokes of Monet's Sunset on a tablet. There are folded notes around with questions about the artworks. After unfolding the notes, users will see answers and encouragement of interacting with the tablet. Then users can print their artworks on postcards. They can take them home or hang their postcards on a postcard wall for visitors to appreciate and discuss.

Interpretation and curation stage: An APE environment with constrained participation

We hope to curate an APE by supporting open-ended exploration with gentle guidance, promoting slow looking (Tishman, 2018), and encouraging visitor-initiated observation, speculation, play, and construction. By shifting the visitors' role from that of recipients to that of participants in the generation of activities, questions, and explanations, visitors are more likely to actively interpret and curate art instead of passively receiving information as APE promotes them to create and delight them with beauty (Simon, 2020). Visitors observe more carefully when drawing over the painting, paying attention to the details. This slow looking process helps visitors discern complexities that cannot be grasped quickly and serves as an important counterbalance to the natural human tendency toward fast looking (Tishman, 2018). This is also a process of co-constructing meaning with other visitors, with questions on the card giving anchoring point. Offering learners a famous painting instead of an empty canvas is to purposefully stage constrained participation that provides opportunities for partial self-expression as meaningful constraints motivate and focus participation (Simon, 2020).

Sharing and discussion stage: Deepen and diversify engagement

The process of discussing and taking home users' artworks is of vital significance. We facilitate this process by creating an emotional relationship between exhibit subjects and visitors by asking them to write their design rationale. The Skyscraper Challenge shows that take-home experiences establish deeper engagement and inspire repeat visitation (Simon, 2020). Museum visitors tend to enact one or various combinations of five museum-specific identities, categorized by Falk as explorer, facilitator, professional/hobbyist, experience seeker, and spiritual pilgrim (Falk, 2006). The idea of a postcard wall where visitors can observe, critique, and collect visitor-created artworks serves to offer opportunities for non-explorers such as facilitators to participate in the exhibit. Here, knowledge and interpretations are not owned by any individual actor but are instead treated as patterns of participation that may be attributed to the group (Knutson, Karen, et al, 2021). The postcard-wall also exists as a mediating barrier to invite visitors to engage with each other in some unusual and valuable ways, avoiding potential awkwardness of in-person critique of visitors' artworks (Simon, 2020).

Current progress

At the time of this poster, we have created a full-scale working prototype of MineArt, received feedback from fellow researchers and participants informally. To adjust to the COVID situation, we moved our exhibit online to a website with flip cards as folded notes and an online gallery as the postcard wall. The poster will be accompanied by an interactive demo.

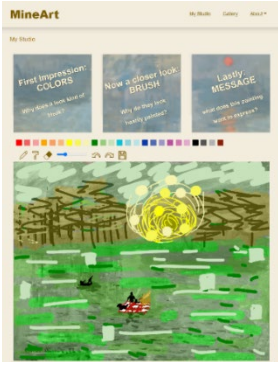

Figure 1. Screenshot. Note the learner-generated artwork based on Monet's

Future work and implications

We plan to launch an initial version of MineArt in early 2021, with the expectation of help inform exhibit curators and create a new experience for visitors to engage with artworks. We hope it will help attract and engage more audiences in the art field. At this time, we are particularly interested in A) better knitting together multiple artifacts into a coherent visiting experience to encourage engagement. B) the emergent learner interactions in its online community and how we can design to better support them.

Outside Learning Environments

Jarek Sierschynski, University of Washington Tacoma, jareks@uw.edu

Abstract: The author examines the notion of learning environments while reflecting on a photographic method as an identity resource. As the photographic portraits migrate across spatial contexts and power relationships, the author theorizes about his research practice and the *settled expectations* in the learning sciences. In search of new constructs, terms and practices that foreground nondominant ways of being, he interrogates the dominant construct of *learning environment* in relation to Black spaces.

Introduction, position and purpose

In this paper, I theorize the notion of learning environments in the context of a longitudinal community-based design research project (Bang et al. 2016) in a cohort-based STEM program for nondominant youth in grades 6-11. Using the ongoing project as the background for this discussion, the goal of this paper is to ponder the ontology of *learning environments*—a term deeply entrenched in the vocabulary and epistemology of the learning sciences—in the context of nondominant, specifically Black spaces in and outside of education. I do so from a position of a learning scientist, a foreigner, a migrant with shifting racialized, cultural and linguistic identities working in a dominant Western academic, colonial space and anti-Black system, i.e., within an inherently violent socioeducational context (Sierschynski, 2019).

Photographs, identities and environments

The focus of our community-based design research project has been a simultaneous decentering of settled, settler-colonial expectations of what constitutes scientific practices and the notion of STEM (Bang, Warren, Roseberry & Medin, 2012). I introduced large scale photographic portraits as a main *identity resource* (Nasir & Hand, 2008; Nasir & Cooks, 2009) that rendered nondominant students, instructors and community scholars aesthetically as *being(s) in practice* and space. Ultimately the photographs became objects that they curated and exhibited in their homes. The movement and transformation of the photographs during the project from research data to sovereign objects, i.e., photographic portraits that were used (or stowed away) by the participants in their homes changed the frame of reference for thinking about my work as a researcher who (with the photos) migrated into the realm of public art, i.e., outside of learning environments.

Politicizing learning environments and commitments

Vakil (2020, p.93) writes, "I begin with the position that disciplines are themselves political in that they are dynamically evolving, historically accumulated representations of knowledge congealed together through complex interactions between history, politics, and culture (Bang & Vossoughi, 2016; Medin & Bang, 2014). Learning environments, therefore, always carry and convey political values." Most of us have been disciplined into understanding our participation as researchers in terms that have been defined without us, for us. One such construct is the heuristic of learning environments (Barron & Bell, 2015), a term that has historically allowed us to define a region of interest with broad connotations of arrangements often divided into formal and informal. In a more recent sociopolitical turn in the learning sciences, accepted heuristics are marked as never neutral, thus requiring both marking of space and self in terms of our positionality and commitments as scientists and citizens (Politics of Learning Writing Collective, 2017; Esmonde & Booker, 2016; Vakil, 2020). The Politics of Learning Writing Collective (2017) reaffirmed a direction that requires "more explicit attention to how power imbues the purposes, mechanisms, and consequences of learning, as well as our approaches to the design, study, and theorization of learning environments" (p.92).

In search of new constructs

What does one do when a construct generates normative epistemological commitments while suppressing nonconforming, nondominant personal commitments? Again Vakil (2020, p.88) points to possible paths worth pursuing: "Sometimes this will entail conceptual layering, thickening, or refining of these constructs, while at other times it may mean inventing new frames for seeing and imagining learning anew." So, what does it look like if a preexistent heuristic is in need of further specificity and why does it matter? Dumas and ross (2016) provide the following example in the context of Critical Race Theory (CRT) by refining CRT to become, BlackCrit, "BlackCrit becomes necessary precisely because CRT, as a general theory of racism, is limited in its ability to adequately interrogate what we call "the specificity of the Black" (Wynter, 1989)….it cannot fully employ the counterstories of Black experiences of structural and cultural racisms, because it does not, on its own, have language to richly capture how antiblackness constructs Black subjects, and positions them in and against law, policy, and everyday (civic) life" (p.417). Reading ross (2016) I was struck by what one of her main participants, Ms. C., a Black teacher said about *Black girl spaces*, i.e., specific, thick, refined, identity sustaining spaces: "A part of "just being them" entails the creation of a space where Black girls can hash out what it means to be themselves in an anti-black, patriarchal society" (p. 47). In the absence of such specificity, "the space couldn't really hold" their identities. Nondominant experiences call for thicker terminology that frame oppressed realities and spaces (see Hartman, 2019, Sojoyner, 2016, 2017 on enclosures). Serving as theoretical entry points for approaching oppressive socioeducational contexts and realities, thicker constructs offer the possibility of being able to represent nondominant spaces in ways that I think learning environments do not.

Conclusion

Given that learning scientists seek to understand learning across contexts, at times our research takes us into home environments. In the context of this project, my community participants and their families ultimately received the photographic portraits in their homes. Several of them curated and displayed the images so that they could be seen. In one case, the family of an instructor hung the portrait in a central location of their living room and begun hanging other family photos around it. Finally, thinking of interacting with spaces in the context of the ongoing, transgressive systemic murder of Black citizens in their homes, the need for nondominant intersectional constructs to talk/think about concurrently about learning and space becomes especially urgent. hooks (1990) writes,

> This task of making homeplace was not simply a matter of black women providing service; it was about the construction of a safe place where black people could affirm one another and by so doing heal many of the wounds inflicted by racist domination. We could not learn to love or respect ourselves in the culture of white supremacy, on the outside; it was there on the inside, in that "homeplace," most often created and kept by black women, that we had the opportunity to grow and develop, to nurture our spirits. (p.384)

Differentiated Instruction in Online Teacher Professional Development

Liam Fischback, Kristin Searle, Colby Tofel-Grehl
lfischback@gmail.com, kristin.searle@usu.edu, colby.tg@usu.edu
Utah State University

Abstract: The integration of computer science into K-12 learning environments requires that teachers be prepared to teach computer science. Due to the pandemic, we transitioned an in-person professional development (PD) for upper elementary teachers to an asynchronous online format. Using reflective interviews, we examine the affordances of this approach. We discuss how the online PD provided advantages for differentiation of instruction and teacher reflection.

Keywords: online, professional development, affordances, differentiated instruction

Introduction and background

Increasingly, meaningful participation in society requires knowledge of computer science and computational thinking (CS/CT). To prepare individuals to become educated citizens capable of computational participation (Kafai & Burke, 2014), governments throughout the world have poured unprecedented resources into computing education, professional organizations have developed K-12 standards for computing and technology usage, and educational systems have worked to integrate computing into K-12 curricula. Despite this push, the number of trained CS teachers remains insufficient to meet the new demand. Researchers in the computing education space have been concerned with how to prepare teachers to teach computing. One of the encouraging avenues to provide CS and CT training to teachers is asynchronous online professional development (PD) (Fishman et al., 2013).

Online PDs are able to provide similar learning as in-person workshops and have been supported by the U.S. Department of Education (2010). High-quality teacher PDs focus on strategies for teaching content and incorporate active learning opportunities for teachers to test and evaluate teaching strategies (Darling-Hammond et al., 2017). Online PDs afford unique opportunities to teachers, such as providing for differentiated instruction by allowing teachers to review new content as many times as necessary to grasp the key ideas or skipping over content that is already familiar. We address the following research question: What are the affordances of asynchronous online professional development for teachers engaged in learning introductory computer science at the elementary level?

Methods

The ESTITCH PD prepares grades 3-6 teachers to implement the ESTITCH curriculum in their classrooms. The ESTITCH curriculum leverages the affordances of making with electronic textiles materials and programmable electronic components that can be integrated into fabric and paper. This allows CS/CT to be integrated with social studies, language arts, and science standards. Originally, we designed the ESTITCH PD to be completed in person, but public health concerns related to the COVID-19 pandemic forced us to move our PD to an asynchronous online model. Teachers were provided with access to a Canvas course that walked them though key ideas in each of the integrated disciplines and provided guides for how to make each of the three ESTITCH projects: (1) a programmable paper circuit timeline, (2) an e-textile quit square based on the patterns of freedom quilts that helped formerly enslaved peoples navigate their passage on the Underground Railroad safely, and (3) a programmable quilt square telling about a meaningful moment in one's life (see Figure 1). We also provided Zoom office hours with project research assistants for troubleshooting and debugging.

Twenty-seven elementary school teachers were recruited from throughout the state of Utah to participate in the online PD, two of whom were master teachers completing the PD for the second time. Of the 27 teachers who started the PD, 23 teachers completed the training. Teaching experience ranged from none to several years. Importantly, some districts in Utah have robust dual-language immersion programs and actively recruit speakers of those languages to come teach at an immersion school for a period of several years. These teachers teach half the day in their native language (e.g. Portuguese, Mandarin, Spanish) while another teacher teaches the other half of the day in English. Our participant population included Portuguese and Mandarin immersion program teachers.

In order to understand teachers' experiences with the ESTITCH asynchronous online PD, we conducted a post-survey that asked about teachers' online PD experiences. We also conducted exit interviews with each of the teachers. We focus on teachers' final reflective interviews about their PD experiences. We examined the interview transcripts using emergent thematic coding (Nowell et al., 2017). We were interested in the affordances of asynchronous online PD for teachers engaged in learning introductory computer science at the elementary level.

Findings

A central finding of our analyses was that teachers liked the built-in differentiation provided by an online asynchronous learning environment. It allowed them to utilize a variety of strategies to master the content and to troubleshoot and debug their own projects, including reviewing the material independently, connecting with other PD participants, and seeking help from the PD providers.

Time to practice and plan

Many of the teachers appreciated the built-in differentiation provided by an online asynchronous learning environment. Unlike in a traditional in-person PD setting, teachers were able to go back and review content until their understanding was sufficient to create a functional project or pause the modules and create a plan for their classroom in that moment. For instance, one teacher observed, "I went to, the lessons that I read through, and then, I would tell myself, maybe I missed something and I need to restart it again. I would follow through the instructions, and it always helped me figure it out in the end (Interview, 07/24/20)." The asynchronous online format allowed teachers to work through the materials at their own pace, to go back and review when their projects did not work, and to create things for their classrooms in real-time. Further, teachers appreciated being able to read other teachers' discussion posts about things that didn't work in their projects or experiences the master teachers had in their classrooms during the previous school year.

Creative collaboration

Prior to implementing the online PD, we envisioned the lack of opportunities for teachers to connect with one another as a major disadvantage, but teachers found creative ways to reach out to one another and collaborate. As one teacher said, "So we just kinda did it together like that through texting or Face-timing each other and working through it and troubleshooting and stuff like that" (Interview, 07/24/20). Often, we think online asynchronous PD will not offer the same opportunities to connect with one another and form meaningful PLC's. While the teachers who worked together on projects typically already knew one another and worked together, the online asynchronous format supported rather than detracted from their ability to work together.

Discussion

When we transitioned from what had previously been a weeklong, face-to-face PD experience to an asynchronous online course, we were concerned that the experience we provided would be less optimal and present teachers with fewer opportunities for developing PLC's. However, as Fishman and colleagues (2013) argued, the online PD was able to provide a similar, if not better, experience than the face-to-face PD. Teachers' reflections highlighted aspects of an effective PD as outlined by Darling-Hammond and colleagues (2017). In particular, it is significant that the asynchronous nature of the online PD provided teachers with the opportunity to work at their own pace, review materials, and learn from their mistakes. In addition, while teachers' abilities to connect with other teachers were more limited, those teachers most likely to form a PLC, such as a grade-level teaching team, leveraged existing connections to help each other with projects. And, when all else failed, teachers were supported by the PD facilitators for Zoom. Because of the asynchronous online nature of the PD, facilitators were able to provide more focused attention to the teachers struggling the most with technical aspects of the projects.

Exploring Gender Gap in Students Understanding, Self-Efficacy and Motivation During Maker Activities

Nicola YL. Law, Sandra Y. Okita, Yipu Zheng, Marcus Y-Y. Cheung
Law@tc.columbia.edu, Okita@tc.columbia.edu, yz3204@tc.columbia.edu, myc2131@tc.columbia.edu
Teachers College, Columbia University

Abstract: This pilot study explored the potential gender gap in understanding, self-efficacy, and motivation while engaging in different making procedures (Assemble or Dismantle). In the Assemble activity, male students made four times more remarks on their understanding than females. The Dismantle activity appeared more compatible with high school/college female students when developing understanding, voicing challenges, contemplating interests, self-efficacy, and motivation. Male students in the Dismantle group showed a decrease in self-efficacy and motivation.

Introduction

The maker movement has provided students opportunities to leverage their developed identities, interests, and knowledge within STEM fields (Martin, 2015). However, gender gaps in maker activities still exist, as makerspaces still reflect stereotypes, lack of women's voices and female leadership roles (Eckhardt et al., 2020). This has led to female students' perceived low competency in technology and making, regardless of their actual competency (Thanapornsangsuth & Holbert, 2017). There is a recognition that maker activities need to be gender-neutral and part of their everyday lives (e.g., dismantling jammed printers). Studies have shown that engaging in reverse engineering, where students assemble and dismantle a product, has helped increase learning, motivation, and perceived helpfulness (Dalrymple et al., 2011). While much effort has been put into maker education, there is limited knowledge of whether gender differences exist in understanding, recognizing challenges, self-efficacy, and motivation while engaging in maker activities. Further examination is needed to explore whether different making procedures (Assemble or Dismantle) may contribute to such outcomes.

Methodology

A total of eighteen students (9 females and 9 males) aged 14-21 from local high schools and colleges (non-science/engineering majors) in Shenzhen and Hong Kong participated in this study. Students were randomly assigned to one of two conditions, Assembling or Dismantling a robotic wind-up generator for 30 minutes (figure 1). In measuring student understanding during the maker activity, all students were asked two questions: "*please put the gear aside for a moment. Can you describe what you understand so far by assembling/dismantling the robotic gear?*" and "*Is there anything you find particularly challenging or interesting?*" These questions were prompted twice, once at the 15 minute-mark (midway), and the second time at the 30-minute mark (at the end). To see how maker activity influences student's self-efficacy and motivation, students filled out a survey before and after the study. The self-efficacy survey used two subsets of the engineering self-efficacy scale: tinkering self-efficacy and design self-efficacy (Mamaril et al., 2016). The survey consists of 11 questions on a Likert scale of 1-6, with 1 at completely uncertain and 6 at completely certain. The motivation survey uses three subsets of the Intrinsic motivation inventory: enjoyment, value and importance, perceived competency (Deci & Ryan, 1986), and consists of 15 questions on a Likert scale of 1-7 with 1 at strongly disagree and 7 at strongly agree.

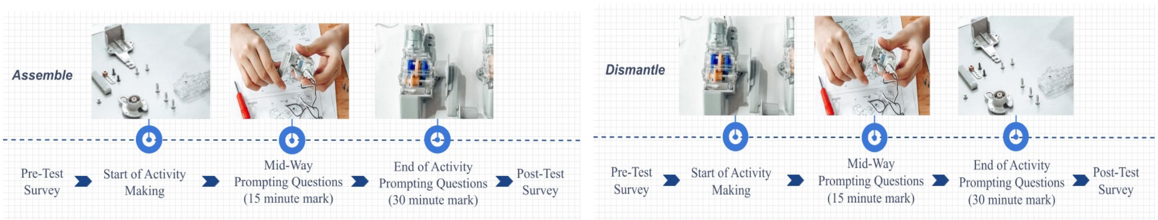

Figure 1. Research Procedure (*Left: Assemble condition; Right: Dismantle condition*).

Analysis and Findings

A coding scheme was developed to label students' remarks from the "understanding" prompt that reflected either basic knowledge on how hand-held generators work (e.g., "*gears move together to drive the* *motor*") or advanced concepts (e.g., "*rotation of the gears generates mechanical energy, which then rotates the motor to generate electricity*") that require interpretation that draws from multiple sources of information. Overall, there was little gender difference in the Dismantle group between female students (total of 22 remarks, avg. 2.4 per student) and male (total 21 remarks, avg. 2.3 per student). In the Assemble group, male students made four times more remarks on their understanding of basic concepts than female students (Male total of 22 remarks, avg. 2.4 per student, Female total of 5 remarks). Interestingly, for female students, the number of remarks on advanced concepts differed significantly across conditions (Female: Dismantle 8 remarks, Assemble 0 remarks), while male students had no difference across conditions (Male: Dismantle 8 remarks, Assemble 8 remarks). In response to the "challenge and interest" prompt question, many of the challenges (41 remarks) addressed either metacognitive reflections (28 remarks, e.g., "*Thinking about where I went wrong. Now I know where I went wrong*") or difficulty in the making (7 remarks, e.g., "can't *unscrew the screw, for some reasons*"). Overall, for both the Dismantle and Assemble group, female students voiced their challenges (Female: Dismantle group 13 remarks, Assemble group 11 remarks) more than male students (Male: Dismantle group 10 remarks, Assemble group 7 remarks). This gender gap was seen in metacognitive reflection remarks (Female: Dismantle group 9 remarks, Assemble group 9 remarks vs. Male: Dismantle group 5 remarks, Assemble group 5 remarks). No gap was seen in voicing difficulty in making. The interest remarks ranged from general (e.g., "it's *interesting to see a lot of gears*") to specific future interests and explorations (e.g., "*I want to try some new methods to assemble and see how many assembly combinations there are*"). In general, male students made twice as many remarks (12 remarks) as female students (a total of 6 remarks) on how the making activity was interesting. Female students in the Dismantle group (4 remarks) made slightly more remarks than those in the Assemble group (2 remarks).

Due to the small sample size and exploratory nature of this study, no extensive statistical analysis was conducted; only preliminary descriptive analysis (i.e., mean and standard deviation) was examined. For self-efficacy, the Dismantle group showed a larger increase from pre- to post-test ($M=.59$, $SD=1.31$) than the Assemble group ($M=.19$, $SD=1.16$). Looking at gender by condition, male students showed a slight increase in self-efficacy for the Assemble group ($M=.25$, $SD=1.55$), but decreased for the Dismantle group ($M= -.23$, $SD=1.21$). For female students, only a slight increase was seen in the Assemble group ($M=.11$, $SD= .64$), but a larger increase was seen in the Dismantle group ($M=1.24$, $SD=1.07$). For motivation, the Dismantle group showed a larger increase from pre- to post-test ($M=.47$, $SD=1.15$), compared to the Assemble group ($M=.15$, $SD=1.14$). Looking at gender by condition, male students showed a small increase in motivation ($M=.21$, $SD=1.53$) for the Assemble group, but a decrease was seen for students in the Dismantle group ($M= -.35$, $SD= .54$). For female students, a slight increase (no difference) was seen in the Assemble group ($M=.07$, $SD= .58$), but a larger increase was seen in the Dismantle group ($M=1.12$, $SD=1.11$).

Implications

This exploratory study offers important guidance for educators when designing maker activities. Educators may want to consider implementing different making procedures to bridge the gender gap, help students voice challenges, foster in-depth understanding, and develop higher self-efficacy and motivation. Compared to Assembling, the Dismantle process seems to allow female students to be more comfortable voicing their challenges and fostering higher self-efficacy and motivation. Other findings are aligned with benefits of using reverse engineering and product dissection in engineering education (Dalrymple et al., 2011). This study provides insight into how gender plays a role in different making procedures, which has not been extensively explored.

Learning in an Arts Education Collective Impact Initiative

Adam Papendieck, The University of Texas at Austin, apapendieck@utexas.edu
Brent Hasty, MINDPOP, brent.hasty@mindpop.org
Jackson Knowles, MINDPOP, jackson.knowles@mindpop.org

Abstract: Collective impact is a well-known approach to changemaking that involves establishing a set of five conditions for change. This mixed methods case study of an arts education initiative combines a longitudinal network analysis of partnership dynamics with a qualitative analysis of situated narratives about learning and partnership to provide a deeper, empirically-based understanding of how and to what extent the conditions of collective impact operate in practice to support changemaking.

Introduction

Collective impact (Kania & Kramer, 2011) is one of a variety of *systems*, *complexity* and *ecological* models of changemaking. The model posits that five conditions for "alignment" should be set for change emergence*: a common agenda, shared measurement systems, mutually reinforcing activities, continuous communication,* and *backbone support organizations* (p. 39). While there has been widespread adoption and funding of collective impact initiatives over the past decade, there have been few empirical studies of how these five conditions for alignment operate on individual or (inter)organizational practice to support collective changemaking. We think the learning sciences can help. The goal of this ongoing study is to apply contemporary sociocultural and sociomaterial conceptualizations of learning as a relational, distributed and situated phenomenon for an empirically-grounded and programmatically helpful analysis of the dynamics and mechanisms of change in a collective impact initiative. We will show how individuals, groups and organizations learn in ways that reconfigure the networked collective and contribute to its impacts.

Framework and method

This is a mixed methods single-case embedded study (Yin, 2014) of the ecosystem of schools and arts education providers assembled via Southtown's (pseudonym) arts education collective impact initiative, the Learning and Arts Collective (pseudonym). The study combines a six-year longitudinal network analysis (Carolan, 2014) of arts education partnerships with a qualitative narrative analysis (Czarniawska, 2004) of partnership types, conditions and dynamics of formation. A cultural-historical activity theory (CHAT) framework (Engeström, 2008) and related sociomaterial concepts of *competence* in *assemblage* (Callon, 1990) and learning as a process of relational *(re)configuration* (Suchman, 2007) are employed to examine how the network is enacted over time at multiple levels (individual to social) per a variety of objects (goals, objectives, projects), and via subjects (partners and schools), communities, tools, rules, norms and roles. This framework helps us examine collective goals and activity as dialogic and multivoiced, and provides a systematic and theory-based way of identifying and interpreting the *contradictions* that schools and non-school arts education partners must grapple with in partnership. From a CHAT perspective, it is these contradictions that drive learning and change in the ecosystem.

Data is drawn from three primary sources: (1) an annual inventory of arts partnerships at all schools in the district collected from 2013 through the 2018 academic year; (2) semi-structured narrative interviews with a purposive sample of schools and arts partners; and (3) digital artifacts of partners and partnership activities (e.g. websites and social media posts). Our analytical approach involved an initial characterization of partners in the district's partnership inventory based on digital artifact data. We tagged partners and partnerships in the inventory according to the apparent *object* (Engeström, 2008) of their partnership activity. Next, we transformed all six years of the partnership inventory into a network graph for longitudinal visualization and quantitative characterization in R using *igraph* and related packages for network analysis. We then developed a purposive sample of partners and schools for interview, selecting participants based on their ability to provide historical narrative accounts of specific network *neighborhoods*, *change trends*, and *objects* revealed in the network analysis. Interviews were used to "provoke the telling of stories" (Czarniawska, 2004) about who partners are, why and how they do what they do, and how partnerships form and evolve. Interviews were transcribed, and our CHAT framework was used to surface and analyze key contradictions emerging within and among individuals, organizations and assemblages in the collective. The stories collected through interviews bring a first-hand *logical* and *narrative* sense (Bruner, 2009) to structural visualizations of network dynamics.

Findings and discussion

Here we present and discuss some preliminary data and findings, and demonstrate how our analytical approach can link diverse, situated achievements of individual and organizational learning to observed network dynamics.

Learning as networked reconfiguration

Overall, we find the arts partnership network to be large and diverse (Figure 1a), comprised of over 778 distinct schools and arts partners and over 10,444 partnership interactions across all years. We see evidence of network-level learning in the form of high-level reconfiguration over time, for instance in the gradual emergence of clusters of school-to-school partnerships (Figure 1b). We also see learning at the level of the individual arts partner, for instance in how the Metro Theater reconfigures and grows its network neighborhood from year to year, embedding itself more broadly and deeply in the arts education ecosystem (Figure 1c).

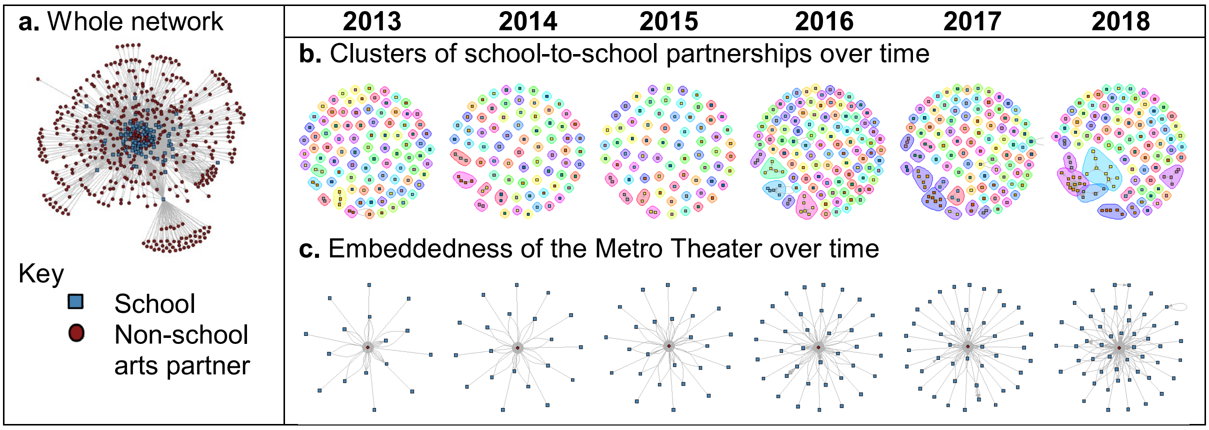

Figure 1. **a.** All partners and partnerships from the 2013 to 2018 academic years. **b.** Clustering over time of school-to-school partnerships (per multi-level modularity optimization algorithm in *igraph*). **c.** Snapshots of the Metro Theater's (pseudonym) network, showing increases in total individual partners and frequency of engagement.

Diverse mechanism of learning

Employing the CHAT framework to analyze narratives of partnership activity, we surfaced a variety of developmental *contradictions* and related learning responses that help explain observed reconfigurations of the network. Some of this learning was supported by the *five conditions* of collective impact. The Metro Theater, for example, reported that the *common agenda* set by the Learning and Arts Collective facilitated the difficult work of justifying and initiating partnerships by reinforcing the fundamental legitimacy of arts education work. The theater also employed the Learning and Arts Collective's *backbone organization* to develop a more synoptic and strategic sense of the overall network of schools. While Metro Theater's early growth in the network depended on passive "word of mouth" relationship-building and the more-or-less random movement of teacher champions from school to school, the backbone organization helped them better detect and strategically select partnerships in ways that minimized what they perceived as unproductive competition, and helped them maximize their impact.

Going forward, we aim to document learning mechanisms and link them to network dynamics.

Conclusion

By combining longitudinal structural descriptions of the arts partnership network with situated narratives of learning and changemaking, this study reveals a bit more of the *social* in a *dynamic* social network, and gives us a better sense of how received concepts and principles of collective impact (Kania & Kramer, 2011) play out in day-to-day practice. We think this can help advance and adapt the collective impact model in theory and practice.

Scaffolding Debugging That Uses Tinkering

ChanMin Kim, Brian R. Belland
cmk604@psu.edu, bbelland@psu.edu
The Pennsylvania State University

Abstract: We designed scaffolding for debugging that uses tinkering. The scaffolding was implemented in a context for teacher learning of computing education. Data included responses to scaffolding prompts, pair debugging processes recorded through video screencast recording, and interviews. We studied how debugging processes differ where the quality of the rules written to justify debugging success (or unsuccess) differ. Findings are organized around the two paired groups who generated different quality of rules in response to the scaffolding.

Introduction

Central to creating culturally responsive computer science (CS) classrooms is a need to prepare teacher candidates to teach CS. Some recent efforts have attempted to identify and strengthen methods of preparing teacher candidates to program (e.g., Kim et al., 2018). But little is known how to facilitate their learning to teach CS in culturally responsive ways. The present study researched methods to do so, through scaffolding for abductive reasoning while tinkering.

Our research question was: How do participants engage in debugging when scaffolded through abductive reasoning?

Theoretical foundation

We used abductive reasoning as a theoretical lens. Abductive reasoning is a process of thinking while attempting to figure out a way of describing a perplexing phenomenon. The process of abduction begins with the best possible guess at the moment and moves to subsequent guesses when the presently tested guess does not explain the phenomenon of investigation (Magnani, 2009; Peirce, 1931-1935).

Method

Paired debugging sessions were recorded using video screencast software. In addition to debugging screencast recordings, pairs' responses to scaffolding prompts were recorded. Our scaffold design for abductive reasoning aimed to (a) leave tinkering as a natural process of debugging and (b) guide rule discovery and refinement. This design was grounded in our prior research in which teacher candidates (a) tinkered through abduction and (b) exhibited reflective debugging, but (c) did not notice a rule across cases (Kim et al., In press). Thus, our scaffolding provided prompts to help them discover a rule that may explain what they were seeing as a result of their tinkering. Artifact-based individual interviews were done after the debugging tasks were completed.

Our analytic strategy involved using conversation analysis (ten Have, 2007) and open and axial coding (Miles et al., 2013) done through the lens of ethnomethodology (Garfinkel, 1967).

Findings and discussion

We present findings from two groups who generated rules of varying quality in response to the scaffolding (e.g., Table 1). As described above, participants were asked to write down a rule that could explain what they just saw during tinkering. The design rationale was to help them (a) connect the change they made in the code to the result they were seeing, (b) reflect on what they guessed as a cause for the buggy code, and (c) notice relations between previously guessed causes and actual results. Such design aimed for reflective abstraction (Abrahamson, 2012) and "plausible abductive generalization" (Rivera & Becker, 2007, p. 140), which would in turn create a collection of potentially relevant rules to be used in abductive reasoning during future debugging.

The following themes were uncovered as to how the debugging processes of these two groups differed.

Reading before (re)writing the code

The initial reading of the given buggy code was rather quick for Group 1. Group 2 read the code line by line also while paying attention to the repeat while block. This finding is interesting because the total time Group 1 spent debugging (38.13 minutes) was longer than that of Group 2 (21.86 mins). Both groups questioned the meaning of "iteration" in the code but Group 1 searched for the term online and read out loud its definition and Group 2 figured out it was a label for a variable. When asked to guess what the code was making the robot do during the initial reading of the code, both guessed incorrectly yet: Group 1 guessed a star shape and Group 2 guessed a pentagon shape. As such, both groups' initial reading of the buggy code was imperfect, but different processes of initial reading, quick versus thorough, were observed between the two groups.

Table 1: Example responses of Group 1 and Group 2 to prompts related to rule generation

	Group 1	Group 2
Final rule	When you put the wrong number in the distance, it will not complete the right shape.	If you program the robot to move forward 50 mm and then have it rotate 45 degrees, it will create one side of an octagon
Rule use plan	We plan on playing around with the numbers in order to make sure we are doing it right.	When considering how many sides we need for a shape, we need to remember to divide the number of sides by 360 to get the angle we should set it to.

Follow-through guesses

Still without information about the programming goal, participants were asked to run the buggy code and guess how the robot would travel. Their guesses were not correct yet: Group 1 guessed a pentagon and Group 2 guessed a hexagon and then a pentagon. But the two groups differed in that Group 2 tinkered through the numeric values in the turn angle in line with their guess but Group 1 did not revisit their guess later.

Parsing the code and robot movement

Group 2 broke down the code in relation to the specific behaviors of the robot whereas Group 1 did not. During such parsing, Group 2 noticed which part of the code worked to lead to a desired behavior of the robot, whereas Group 1 did not notice the misfunctioning of the angle value and ended up changing the correct distance.

Conclusion and implications

The unique contributions of this study are (a) the asset-based scaffolding in which tinkering through abduction among teacher candidates is respected and utilized, and (b) the potential lessons on how tinkering through abduction can be valued and supported among youth learning to program. This in turn has the potential to invite teachers and youth from diverse backgrounds to identify with and engage in programming.

Designing Artificial Intelligence (AI) in Virtual Humans for Simulation-Based Training with Graduate Teaching Assistants

Chih-Pu Dai, Fengfeng Ke, Zhaihuan Dai, Luke West, Saptarshi Bhowmik, Xin Yuan
cdai@fsu.edu, fke@fsu.edu, zd12@my.fsu.edu, lawest@fsu.edu, sb17s@my.fsu.edu, xyuan@cs.fsu.edu
Florida State University

Abstract: In this case study, we explored the design and usability of an AI virtual human design architecture. Data from 50 hours of project meetings and 35 hours of user-testing and prototyping sessions contributed to the preliminary results. The study findings indicated the potential of using AI-integrated virtual humans to support conversational and interactive training for student instructors in an open-source virtual reality environment. Moreover, the AI student prototyped was found to be authentic and semantically meaningful.

Introduction and theoretical background

Teaching is complex problem solving. Prior research demonstrated that authentic simulation-based learning can facilitate knowledge application and skills practice for learning to teach (Chernikova et al., 2020). However, designing virtual humans with artificial intelligence (AI) to convey naturalistic interactions with student instructors in virtual reality is still a challenge. Furthermore, empirical research is lacking on how to design AI virtual humans using an interdisciplinary and systematic approach.

According to Hayes-Roth and Thorndyke (1985), AI typically manipulates multiplex architectures to represent ill-structured problem-solving solutions. To represent the AI architectures for educational purposes, understanding human behaviors and modeling human cognition and character traits are integral parts of virtual human design (Johnson & Lester, 2018). To this end, Nye et al. (2014) used semantic analysis with a discourse framework to create natural language dialogues to promote learners' (i.e., graduate teaching assistants in our study) knowledge application and problem-solving skills development. Essentially, *expectations-misconception* mechanism was used to tailor natural language dialogues that model student knowledge and individual differences so that the virtual students can be designed to stimulate preservice teachers' practice with the targeted activities (e.g., Nye et al., 2014; Paladines & Ramírez, 2020). However, it remains a challenge to design such natural-language-enactive virtual humans in 3D virtual environments that utilize low-level implementation programming languages such as Linden Scripting Language (LSL) (Ke et al., 2020). Nevertheless, an open-source, multiuser virtual reality (VR) platform like *OpenSimulator (OpenSim)* is usually more customizable and accessible and hence are more likely to be scalable and equitable for a larger population. The current study is an ongoing exploration of designing AI in the virtual world. The following question is explored: *How does an AI-integrated virtual human design architecture and process come about in a VR simulation-based learning environment?*

Method

As part of an ongoing design-based research project on simulation-based training of student instructors, we documented three iterative cycles of virtual humans (or virtual students, in this study) design in a simulation-based environment in *OpenSim*. We employed a case study approach to investigate the design experience and artifacts in situ. Each iterated design cycle, including its design activities and artifacts, works as a design case that is bounded in a twenty-five-week design period. Interactions and behavioral data elicited in the iterative design process was collected from a total of 50 hours of project meetings, 22 hours of paper prototyping sessions, and 13 hours of functional virtual human prototyping. The paper prototype was made via Microsoft excel sheet with comprehensive syntaxes whereas functional prototypes were created first with RPG Maker MV and then in *OpenSim*. We triangulated the data collected from meeting notes, design documents, design artifacts, screen recordings, and semi-structured interviews with the in-field test users. In the following sections, we present the preliminary results from the open coding analysis of the current case study.

Results

Process and architecture of the AI virtual human design

To develope dynamic, conversational, and interactive AI-integrated virtual humans (see Figure 1, left), we developed an architecture that utilizes both high- and low- level programing languages and external knowledge database with text mining techniques (see Figure 1, right). For agent modeling, we first reviewed the literature on learning and individual differences to outline salient traits and characteristics of virtual humans. Next, we finalized seven individual differences with either a three-point or two-point scale for the machine to interpret as the default characteristics of the virtual students. For example, motivation (0=low; 1=medium; 2=high) or cognitive fixedness (0=no; 1=yes). These characteristics result in four main categories of virtual student states: affective, cognitive, metacognitive, and behavioral. These states are dynamic and changeable from the interactions with the graduate teaching assistants and the teaching contexts (i.e., global rules). The states transition is engineered with external knowledge database and the communications between high-level programming languages and LSL.

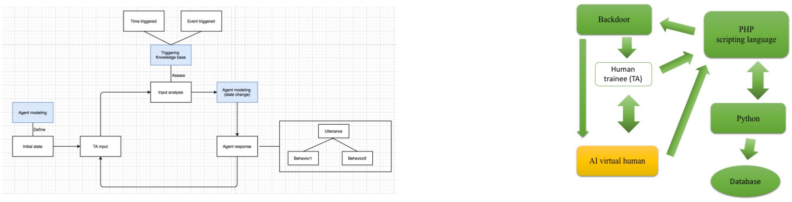

Figure 1. The virtual humans architecture designed for virtual reality using *OpenSim*.

Virtual humans' usability

The preliminary results with front-end users (i.e., expert instructors and designers) and college students (i.e., the population of the agent being modeled) suggest that the design of the virtual students is authentic and semantically meaningful. All participants provided positive feedback. For example, being asked if the virtual students design prototype is naturalistic, Mateo (pseudonym) responded, "*Yeah, I can see that happening.*" The design of challenging teaching situations also reflected what college students experienced in daily life: "*I know there was one student that was annoying that I've come across in all the classes I've taken so far…she would asked questions that…don't really applied to what he* (re: the professor) *was teaching*" (Mateo). Moreover, Shelly (pseudonym) revealed the important role of psychology and agent modeling in the AI virtual human design: "*it's good to know how people work when you're teaching them."* For disruptive student agent behavior design, Shelly commented: "*some students are very extroverted and they're very vocal about how they feel…(their complaints) makes me uncomfortable, like the conflict between a teacher and student.*" These comments suggest that the current virtual student agents were associated with a balanced design between the behavioral and affective states as well as the cognitive and metacognitive states.

Conclusion and Implications

This current study demonstrates the potential of designing and using intelligent virtual humans in a virtual environment (Ke et al., 2020). Specifically, the proposed design architecture consists of state-of-the-art mechanisms and has the potential to tailor natural language dialogues (Nye et al., 2014; Paladines & Ramírez, 2020) between the graduate teaching assistants and virtual students in a 3D virtual world based teaching simulation. Current user-testing data indicate that the designed virtual students are perceived as authentic and semantically-meaningful. This design-based research should foster conversations between and reflections of interested stakeholders in virtual human design and development for teaching and learning in a virtual world.

An Assessment Focused Research-Practice Partnership

Keisha Varma, Tayler Loiselle
keisha@umn.edu, loise011@umn.edu
University of Minnesota

Abstract: In this proposal we present a narrative account of a research-practice partnership focused on creating an assessment that could meet the needs of teachers as an activity they could enact to support their instruction and assessment goals and also meet the needs of researchers as a research measure. We highlight the way the Draw-A-Scientist Task (DAST), a tool for revealing students' images of scientists, was introduced at a teacher professional development institute and adopted by middle school science teachers. By following a co-design approach, we created a strong research-practice partnership. Our findings summarize the nature of the research-practice partnership and outcomes. This work is a critical illustration of the importance of considering teachers as true research partners. This collaboration afforded the development of a tool that they could use to elicit students' ideas about science and also reveal some of their personal identities.

Keywords: Professional Development, Teaching

Introduction and theoretical frameworks

Introduction

This paper describes a research-practice partnership where teachers and researchers co-edited the Draw-a-Scientist task to measure middle school students' identity using the Draw-a-Scientist Task (DAST) (Chambers, 1983). The DAST is designed to measure students' perceptions of scientists and their ideas about the nature of science. In the current work, teachers and researchers worked together across two years to modify and enact the Draw-a-Scientist task for use in middle school science classrooms.

This work builds on the rich history of research-practice partnerships in the learning sciences (Penuel & Gallagher, 2017). The research question driving this work is "What are the outcomes for teachers and researchers who are involved in a research-practice partnership focused on co-creating a student-centered assessment?" Our narrative description of the work provides an account of how teachers and researchers worked together to build trust and create a tool that was beneficial for instruction as well as research.

The Co-Design Process

The co-design process we engaged in aligns with the definition of co-design as a collaborative process involving teachers and researchers/developers working together to create an educational tool by engaging in iterative cycles of design, enactment, and evaluation (Penuel, Rochelle, & Shechtman, 2007). Typically, co-design research focuses on developing new technologies that are classroom innovations This work is unique because it invites teachers to co-design a paper-and-pencil based assessment as a classroom "innovation".

Methodology

Research Context

Our research took place across two years as part of a larger project being enacted in four middle schools with diverse students and families from rural, suburban and urban communities. In this study we focus on the teachers across two academic years and summers. They participated in summer professional development meetings to learn about the social learning environment, Flipgrid (Flipgrid.com). At these meetings they were also introduced to approaches to create culturally responsive learning experiences that invite students and parents to make connections between their everyday lives and the science being covered in their classes. A major facet of our research is to measure students' science identity. This paper focuses on our effort to include teachers as collaborators in this particular aspect of the project. We selected the draw-a-scientist task to measure student identity and included teachers as partners to modify the task to fit their instruction needs as the researchers also considered how it would meet their research goals.

Data Sources
Teacher focus groups were conducted at the end of each summer professional development (PD) institute. Follow-up focus groups were hosted during the academic year Individual teacher interviews were conducted at the end of each academic year.

Findings

The co-design process: Modifying the DAST
Our collaboration centered on a desire to make sure that the task would be developmentally appropriate, culturally responsive, and gave us insights into students' identities. Teachers were able to create instructions and versions of the task that were most appropriate for their classes. Some also included reflection questions to elicit details about students' drawings and to prompt them to further reflect on their STEM identities and interests in STEM careers. During the year two professional development meeting, teachers collaborated to create a single approach for administering the task and standardized the reflection questions.

The redesigned DAST in action: Research and pedagogical goals
During both professional development meetings, teachers and researchers agreed on the need to better understand students' science identities. Working together, they were able to co-design a tool, the modified DAST that met multiple goals. In Year 1, although teachers administered four different versions of the task, they eventually agreed that one standardized version, along with a reflection question worksheet one teacher created, would be more appropriate for their students as well as provide more information about how students' are situating their own science identities with the images of scientists they drew.

The impact for professional development: Shared goals and trust building
Co-designing the modified DAST helped the research team to understand teachers' goals of developing something that would serve as a class activity as well as a measurement tool. In most cases, their priority was providing students with an opportunity to share their ideas and reflect on their identities. Some teachers used the task as a graded homework assignment and others presented it as a way to get to know their students.

Teachers and researchers discussed the way that the instrument would be introduced, and modified the reflection questions together. To further meet the needs of the researchers, teachers agreed to administer the instrument to their students during a particular week of the fall semester.

Discussion
Our partnership illustrates the power of a relationship built based on a shared goal of eliciting students' ideas about science and also reveal some of their personal identities. Teachers are being asked to make evidence based decisions at the same time as researchers are being asked to develop authentic assessments to measure the impact of interventions that affect difficult to measure constructs such as identity. Co-design activities can serve practical goals to create useful tools. During the co-design process, teachers and researchers can develop critical relationships that advance research and enhance pedagogy.

Designing Effective Automated Feedback for Modeling Tools

Mara Negrut, Kihyun Ryoo
nmara@email.unc.edu, khryoo@email.unc.edu
University of North Carolina at Chapel Hill

Abstract: This poster reports the results of design experiments exploring the effects of two forms of automated feedback in modeling tools on eighth-grade students' understanding of chemistry (Study 1) and life science (Study 2). Eighth-grade students in each classroom were randomly assigned to receive either Elaborated-Visual (EV) or Reflective-Visual (RV) feedback during modeling activities. Although both forms of feedback significantly improved all students' science learning, the results revealed mixed effects of EV and RV feedback on students' performance on the explanation and modeling items.

Keywords: automated feedback, modeling tools, chemistry, life science

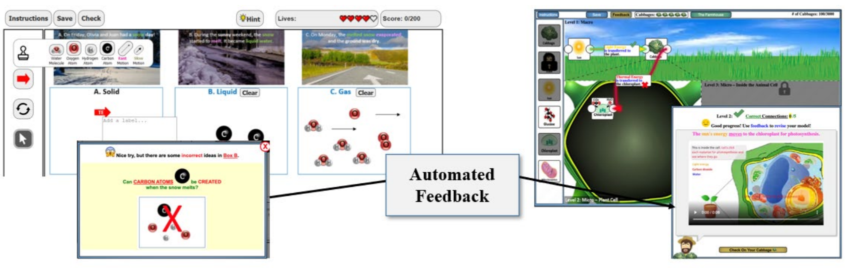
Introduction

Recent developments in automated scoring and feedback technologies allow modeling tools to analyze student-generated visual representations of complex scientific systems and provide real-time feedback based on individual student performance (Luckie et al., 2011; Pei et al., 2019). Although several studies have shown that the use of automated feedback can lead to improved learning outcomes (e.g., Linn et al., 2014; Van der Kleij et al., 2015), there are inconsistent findings about which forms of automated feedback can be most effective for developing and revising visual models of scientific phenomena. For instance, research has revealed mixed benefits of elaborated feedback (e.g., accurate explanations) and reflective feedback (e.g., hints) for different learning tasks (e.g., Ryoo & Linn, 2016; Shute, 2008; Wojcikowski & Brownie, 2013). In addition, recent studies have shown conflicting evidence about the value of providing additional resources or examples in feedback (e.g., Finn et al., 2018). To address the gap in the current literature, this study explored how Elaborated-Visual (EV) and Reflective-Visual (RV) feedback in modeling tools helped eighth-grade students improve their understanding of unobservable scientific phenomena in chemistry and life science.

Study 1

Study 1 explored the effects of EV and RV feedback in a modeling tool on eighth-grade students' understanding of chemistry. Students in each classroom were randomly assigned to either the EV (N = 62) or RV (N = 65) feedback condition. Within each condition, students received visualization-rich inquiry instruction in pairs to explore what happens to energy and matter during a phase change. Prior to and after the study, students individually completed identical pre- and post-tests consisting of open-ended modeling and explanation items.

On days 3-4, pairs were asked to develop visual representations of the relationship between energy and molecular behaviors when snow melts and evaporates by using stamps, arrows, and labels (see Figure 1). Upon submission, they received either EV or RV feedback based on specific non-normative ideas (e.g., molecules breaking up) and the presence of key concepts (e.g., spacing between molecules) represented in their work. Both forms of feedback informed students about the location of the error in the submitted model. Next, the EV feedback provided an elaborated explanation about a key scientific concept with a visual resource, while the RV feedback provided the same visual resource with a reflective question to facilitate discussion about the target concept. Students revised their models using the received feedback multiple times. After the activity, students rated and commented on the usefulness of the feedback.



(a) (b)

Figure 1. Interface of modeling tools with automated feedback used in Study 1 (a) and Study 2 (b).

Analyses of pairs' log data showed no significant differences between the two feedback conditions in the number of model revisions and students' perceptions about the usefulness of feedback. 53% of the EV group found the feedback helpful or very helpful because its specific information helped them understand what they "need to add or what you are missing." 48% of the RV group commented that the feedback "led us down the right path in order to fix our mistake" and provided "suggestions on how we could fix it."

The results from the individual pre- and post-tests showed that both EV ($p < .001$) and RV ($p < .001$) feedback forms significantly improved students' understanding of the target concepts. Interestingly, the RV group demonstrated significantly higher learning gains on the explanation items ($p < .05$), compared to the EV group. However, no significant difference was found between the two conditions on the modeling item.

Study 2

Study 2 examined the effects of EV and RV feedback in a life science modeling tool on eighth-grade students' understanding of photosynthesis and cellular respiration. The procedure was identical to the one used in Study 1. Students in each classroom were randomly assigned to either the EV (N = 48) or RV (N = 46) condition. During the inquiry instruction, pairs developed and revised visual representations of how energy flows between plants and humans at the macro and micro levels by making connections among icons and assigning labels to describe the target concepts (see Figure 1).

The results showed that both groups, on average, revised their models six times, and 70% of each feedback group rated the feedback as helpful or very helpful. Students in Study 2 particularly appreciated having feedback with visual resources, stating that "the videos showed what happens to energy when it enters the chloroplast" and "it really helped visualize the functions of cellular respiration." Consistent with Study 1, both EV ($p < .001$) and RV ($p < .001$) groups demonstrated a significantly enhanced understanding of the target concepts on the post-tests, compared to the pre-tests. However, the results did not show any differences in students' learning gains between the two feedback conditions.

Conclusions

This study extends the current literature by demonstrating the significant effects of EV and RV forms of automated feedback in modeling tools on middle school students' science learning in chemistry and life science.

The results revealed that both forms of feedback led to an increased number of model revisions and significant learning gains from individual pre- to post-tests. Students in both conditions found the received feedback helpful in revising their work. However, the significant advantage of RV feedback, compared to EV feedback, was only found in students' explanations in Study 1. Given the conflicting results, more research is needed to better understand under what conditions EV and RV feedback can support student learning across different modeling tools and various science topics.

The Human-Interpreter Problem in Youth Encounters with AI

Eric Greenwald, University of California, Berkeley's Lawrence Hall of Science, eric.greenwald@berkeley.edu
Maxyn Leitner, University of Southern California Institute for Creative Technologies, leitner@ict.usc.edu
Ning Wang, University of Southern California Institute for Creative Technologies, nwang@ict.usc.edu

Abstract: Artificial Intelligence's impact on society is increasingly pervasive. While innovative educational programs are being developed, there is yet little understanding of how pre-college aged youth engage with and construct understanding of core AI concepts and strategies. In this paper, we discuss emerging findings from a cognitive interview study with middle school and high school students to better understand how students learn AI concepts. This research was supported by the National Science Foundation under Grant 1842385.

Introduction: The human interpreter

When a novice programmer encounters a debugging problem in computer science, the novice sometimes imbues the program with a human's ability to interpret ambiguous instructions (Spohrer & Soloway, 1986). This may be especially common where the correct interpretation is obvious, or incorrect interpretations are exceedingly unlikely (Van Someren, 1990). The implicit expectation is that there is a human interpreter between the computer and the code mediating implementation of the code. Across a set of extended cognitive interviews with middle and high school aged youth, we observed evidence of an AI variation on the human interpreter problem: when a novice works to figure out how an AI system might solve a real-world problem, they sometimes imbue the system not only with computational capacity, but also with capacity to infer and reason about human motivations. We hypothesize that youth may begin with a working theory of AI that assumes general intelligence for the system, including the capacity to recognize and reason from human motivations.

Methods

We conducted cognitive interviews with a convenience sample of eight students (12 to 17 years old) from a private school located in the western United States as they worked through five AI problems. As youth worked through the problem set, the cognitive interview employed a semi-structured protocol to elicit student thinking as each student initially encountered each problem, attempted to solve the problem, and in reflection after they had settled on a solution. In-the-moment scaffolding was provided throughout each interview to enable students to reveal thinking across each step of the solution, surface and test emerging ideas about why a student might be stuck, and to disambiguate between superficial challenges and conceptual difficulties (see, Greenwald, Leitner & Wang, 2021, for a full description of methods). The sample was racially and ethnically diverse and also higher-resourced than that of the average public school. Given persistent inequities in computer science academic and career pathways, as well as broader questions of access and privilege across society, the sample presents limitations for generalizability that will be important to address in future studies.

To analyze the video-recorded interview data, we created excerpts of each student's work on each problem, and applied codes directly to the video excerpts according to the problem type using Dedoose (2018), a mixed methods data analysis tool. We then completed two passes through the data. With the first pass we viewed each interview in sequence, generating and applying a set of broadly applicable codes (e.g., problem type, challenges, scaffolds); then, we compiled the excerpts by problem type and viewed the variety of student responses on each problem together. In this second pass through the data, we drew from the principles of grounded theory (Glaser, 1992), to iteratively introduce new codes as themes emerged, which we then added to and revised through successive passes through the data, continually comparing the emergent codes against the data. These initial codes were revised for consistency, then applied systematically across the data.

Initial findings: Insight into students' working theories of AI systems

As previously reported, students in our sample were unfamiliar with parsing the world in terms an AI system can operate on (Greenwald, Leitner, & Wang, 2021). A challenge for all students interviewed, including those with advanced mathematical skills, was recognizing how a problem in the world could be made amenable to the computational power of an AI system. That is to say, students needed support in conceiving a problem space in a way that would enable an AI system to solve it. Students' initial uncertainty, however, did shed light on possible working theories students brought into the AI problem solving tasks.

For the decision tree problem, students were presented with a data table about past behavior and tasked with helping a friend decide whether or not they would wait to get a seat at a restaurant. With this problem, multiple students approached the task of finding patterns in the presented data set by first speculating on the underlying motivations that may have led to the data itself. For example, when presented with the data table and the overarching problem of imagining how an AI system might leverage the data to make decisions, students typically began by inferring from their own experiences and intuitions about eating out to propose reasons that a family might wait or not wait at a table. The dialogue excerpted below occurs after the variables and values in the data table were explained by the interviewer:

> Interviewer: If the goal is to predict whether or not the family is going to wait, how could this data table be used to make that prediction?
>
> Student: All the ones that waited, said that they were hungry; they had a reservation, and it was a pretty expensive restaurant, so they waited And it was a short wait, so they probably...and they were hungry, so they wouldn't want to leave their reservation; same with this one, they also had a reservation and they were hungry, and there was no alternative, so they probably would...they waited as well.

Similar student responses across the interviews suggest that when considering how AI systems use data to make decisions, students begin by drawing on prior experience to suggest underlying motivations within the decision space, rather than attending to features of the data themselves. A possible interpretation is that the student was attempting to understand the family's motivated reasoning for waiting or not waiting as a path to devising an AI solution that could leverage that reasoning. While building understanding by drawing on prior experience is often a productive move, we note that each of the student's conjectures in the excerpt above (hunger level, reservation, price) conflicts with the data as presented in the table. For multiple students, we also observed that this reasoning about diners' motivations as a path for AI system decision-making often persisted after explicit call-backs to the observable features of the data table.

Discussion: A call to explore working theories of AI among youth

Findings suggest that students may be including notions of intent and motivation in their working theories of AI systems: that because *human* intelligence includes the capacity to infer and make use of one's reasoning behind a decision, perhaps then artificial intelligence shares this capacity. The version of AI common in science fiction and popular culture is often that of an intelligent system more or less similar to (or advanced beyond) the intelligence of a human: a yet-to-be realized instantiation of artificial general intelligence, or artificial super intelligence. Evidence across several interviews suggests that students may be drawing on these models of AI when encountering AI problems. It is also likely that students' initial focus on the rationale behind the data dovetails with long-documented difficulties students have analyzing and interpreting data more broadly (Curcio, 1987).

Further research is needed to better understand students' working theories about AI systems, and how those theories may mediate students' developing understanding within the learning experience. Interviews suggest a related need to support students toward a more generalized understanding of how AI systems can be applied to problems, and how problems can be reimagined to be solvable by AI systems. This finding adds weight to efforts aimed at promoting "explainable AI" (Gunning & Aha, 2019) that makes the decision-making of AI algorithms transparent to users. Through its transparency, explainable AI can create opportunities to make AI concepts accessible, in part by supporting youth in developing working theories about how such systems function.

Abstract: This study investigates the associations of spontaneous *dynamic gesture* and *transformational speech* with the production of *deductive proofs* in participants' reasoning about geometric conjectures (N=77). Although statistical analysis showed no significant association, the result suggests that purposefully including directed actions and pedagogical language in interventions could promote the production of deductive proofs.

Keywords: Geometry, Proof, Dynamic gesture, Transformational Speech

Nathan and Walkington (2017) developed the Grounded and Embodied Mathematical Cognition (GEMC) model (Figure 1) based on the Gesture as Simulated Action framework (Hostetter & Alibali, 2019) and the Action-Cognition Transduction hypothesis (Nathan, 2017). They showed how the activation of both the sensorimotor system and the language system is necessary, but perhaps not sufficient, for a learner to produce a mathematically *valid proof-with-insight*, a conceptual understanding of a conjecture that is correct, logical, and generalizable. The GEMC model posits that *dynamic gestures* and *transformational speech* – both the embodiments of simulated mental action – are reliable predictors of valid proofs-with-insight for mathematical conjectures (Nathan et al., 2020; Pier et al., 2019). *Dynamic gestures* (DG) depict transformational operations on mathematical objects (e.g., rotation or dilation; Figure 2). *Transformational speech* (TS) verbally articulates transformational operations (e.g., "You can increase or decrease the lengths of the sides and still have the same angles."). However, further investigation is needed on the extent of DG or TS's role in generating *deductive* mathematical proofs. Therefore, the research question for this study is: *When students produced valid proofs-with-insight, is there an association between their utilization of DG and TS and the production of deductive proofs?* A proof is *deductive* when it (a) is generalizable and holds for all cases under consideration, (b) utilizes clear logical inferences, and (c) exhibits goal-oriented thinking – where the prover progresses systematically with goals in mind and correctly anticipates the outcomes of the proposed operations (Harel, 2007). This study examined the role of DG and TS in the production of deductive proofs. We expect that the participants who utilized both DG and TS simultaneously while proving would produce more deductive proofs than those who did not.

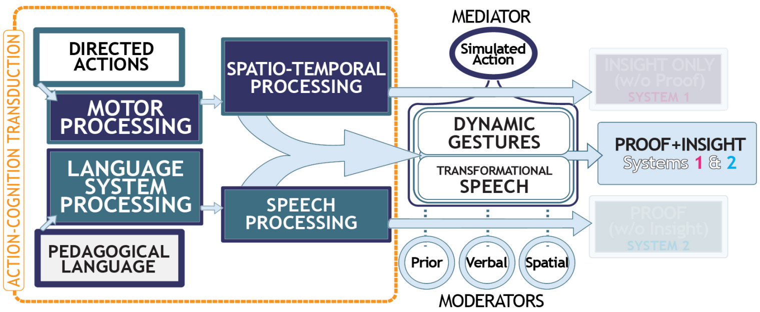

Figure 1. Grounded and embodied mathematical cognition (GEMC) model (Nathan and Walkington, 2017).

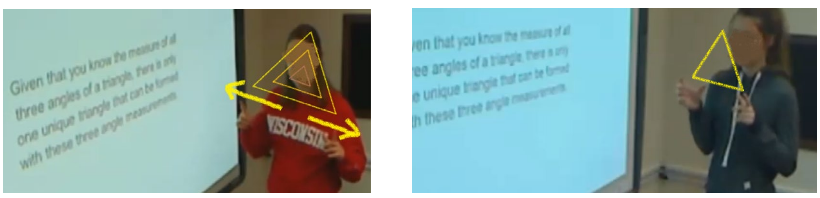

Figure 2. Dynamic gesture (left) and non-dynamic gesture (right).

This study is a post-hoc analysis of the data of 77 valid proofs-with-insight from college students who were recruited to prove four geometric conjectures. Participants were asked individually to prove the four conjectures projected on a screen. Figure 2 depicts students' gestures in response to one of the conjectures, 'Given that you know the measure of all three angles of a triangle, there is only one unique triangle that can be formed with these three angle measurements.' Their responses were video recorded and transcribed.

For this study, a *valid proof* was coded as a correct judgment on the given conjecture's truth value and *insight* as including key mathematical ideas of the conjecture. Then, each transcript of 77 valid proofs-with-insight was binarily coded (i.e., 0/1) in three categories: *DG*, *TS*, and *deductive*, then categorized into four groups by their utilization of DG and TS (Table 1). This random sampling of mutually independent observations satisfied the assumptions for a Fisher's exact test through which we tested whether there was an association between the utilization of DG and TS and the total number of deductive proofs produced.

Table 1: The contingency table of deductive proofs in the four groups by the DG/TS utilization

	DG & TS	DG	TS	None
Deductive	46	19	4	4
Non-deductive	2	1	0	1

Although the raw numbers seem favorable (Column 1, Table 1), statistical analysis showed no significant association between the DG/TS utilization and the production of deductive proofs ($p = .442$) and no significant difference in deductive proof production between the group who used both DG and TS and the groups who did not ($p = .629$). These null results contradict our hypothesis that DG and TS combined would induce more deductive proofs.

Nevertheless, we maintain that this anecdote is inconclusive to refute GEMC model for three reasons. First, multiple previous studies in the same line of research have shown significant associations of the concurrent occurrence of directed actions and transformational language with improved proving practices (e.g., Pier et al., 2019; Williams-Pierce et al., 2017). Second, the GEMC model posits DG and TS as necessary but not sufficient contributors. Third, the small sample size and low statistical power may have resulted in the high p-values. Consequently, we argue that our analysis suggests that spontaneous expression of transformation may be insufficient in generating deductive proof, a more rigorous proof form than valid proofs-with-insight. In turn, the result may hint at the need for interventions to include directed actions and transformational pedagogical language, as predicted in Nathan and Walkington (2017). Future research will investigate other possible contributors to deductive proof production.

Abstract: Learning about science from an inquiry question across a unit is challenging. We examined whether students with more appropriate goals and plans for a science investigation (i.e., task models) wrote more complete culminating arguments. Students who perceived the unit was about reasoning had less evidence in their essays than those that did not. This suggests that some students need supports to understand the role of reasoning to guide inclusion of evidence in their final arguments.

Keywords: argumentation, explanation, task model, science learning

Introduction

U.S. students are increasingly engaging in inquiry tasks to learn about disciplinary core ideas, science and engineering practices, and crosscutting concepts (Achieve, 2013). By interweaving these three dimensions to answer a question about an authentic anchoring phenomenon (e.g., why were Mesosaurus fossils found in both South America and Africa and how did they get so far apart?), students should begin to develop scientific thinking by engaging in both the construction of explanatory models and argumentation (Achieve, 2013; Osborne, Erduran, & Simon, 2004). Argumentation in science entails the development of claims, the collection of supporting evidence, and the use of key scientific principles and core ideas to reason from evidence to claims (Berland & Reiser, 2009; McNeil & Krajcik, 2012; Osborne & Patterson, 2011). Inquiry learning in 7th grade often involves engaging in argumentation and reasoning across multi-week units. In this situation, it would benefit students to understand how all the individual investigation subtasks contribute to the overarching goal of the unit. Students must know what they are being asked to do for each subtask (i.e., goal state) and how they can do this (i.e., strategies), in order to then assign value to each goal (i.e., interest and motivation for doing the work). We define this regulatory structure as a task model (Britt, Rouet, & Durik, 2018), which is the students' representation of the task during learning. In the current study, we explored students' task models about the point of the unit and the important content they gained from the unit. Then we examined whether students' task model content predicted what they included in their final arguments. In general, we expected students' task models would help explain what was included and not included in their final essay.

Methods

Fifty-seven students participated from three 7th grade science classes taught by the same teacher in Chicago Public Schools (n_s = 25,15,17). After obtaining consent, researchers collected data in March of the 2019-2020 school year. The school district used a science curriculum centered around the Next Generation Science Standards (Achieve, 2013). Each unit presented a hypothetical or real-world scenario with a unit investigation question and built toward a culminating argument essay. During instruction, the teacher used several supportive tools including an *Investigation Steps Chart*, that included five questions to help students monitor and guide inquiry activity (e.g., "How will we use the materials like a scientist to answer the investigation question?" "What have we figured out that helps us to answer the investigation question?" "What do we still need to figure out?"). After finishing their second unit of the year, students completed an eight-minute Task Model survey for that unit. In prior work with adults, our task model survey asked participants to reflect on their goal(s) and actions for achieving each goal. To modify this task for a 7th grade population, we asked students two questions to try to capture the goals in the forefront of the students' minds ("What is the main point of this unit?", "Describe the three most important ideas you learned from this unit."). Then two days later, they had 60 minutes to write their unit argument essay. The instructions prompted students to use evidence to support their claim and to explain their reasoning (i.e., the unit's key reasoning concepts). Students had three resources available to could use when writing their essay: a word bank, their completed Investigation Steps Chart, and notes from a reasoning tool activity that guided students to connect claim-evidence-reasoning.

Results

An ideal essay answer was parsed to identify the key arguments idea units: 15 evidence units (e.g., Earthquakes occur in a pattern along the boundary between the South American and African plates), 10 reasoning units (e.g., which tells me that the plates move), and seven possible pairings of evidence and reasoning. Then the student essays were scored for these units. The Task Model surveys were also scored for the same evidence and reasoning idea units and pairings of evidence and reasoning. Scores were computed as proportions since the number of possible ideas varied between the task model survey and the final essay. Interrater reliability revealed high agreement between two of the authors' judgements (Kappa = .84).

In the argument essays, many students included evidence-reasoning pairs (25%), unpaired evidence (30%), and unpaired reasoning (5%). In the Task Model, students included unpaired evidence (26%), and unpaired reasoning (17%). Evidence-reasoning pairs were not used in scoring the Task Model as they were not as common (1%). A multivariate regression was conducted with evidence and reasoning from the Task Model survey predicting the evidence and reasoning and pairings in the final essay. Reasoning in the Task Model significantly negatively predicted the evidence in the essay $F(2,52) = 2.79$, $p = .05$, $\eta_p^2 = .139$. As students included more reasoning in the Task Model survey, the amount of evidence in the final essay decreased by -.327, $p = .005$.

Discussion

This study presents an exploratory investigation of students' task model knowledge and how it predicts the elements that they include in their unit-culminating argument essay. Students who mentioned that the unit was about key scientific principles and core ideas (i.e., reasoning idea units) included less supporting evidence in their essays. Focusing on curriculum-provided reasoning did not help the students include evidence or make evidence-reasoning pairings in their essays. This finding points to the need to emphasize using curriculum-provided reasoning to learn evidence, practices, and how to think like a scientist in inquiry learning scenarios. Otherwise, students may not benefit from learning these practices and other important concepts intended in inquiry learning. Of course, all these observations are tentative as we only have three classes taught by one teacher. Yet, there was variability in the extent to which students saw evidence as the main point of the unit. Future work will include examining these relationships with a larger sample of classes and different units in the curriculum. This is an exciting first step in connecting Task Models to learning outcomes in this age group.

Family-Friendly Teacher Professional Development

Marcelo Worsley, Sarah P. Lee, Stephanie T. Jones
marcelo.worsley@northwestern.edu, spl@u.northwestern.edu, stephanie.jones@u.northwestern.edu
Northwestern University

Abstract: This paper examines a professional development model that centers teachers and their families and was intended to deepen teachers' practices and engagement with making. This program was initiated by teachers who wanted to participate in professional development but faced constraints by the need for childcare. This program highlights what is possible when teachers are positioned to learn alongside their family members and are encouraged to draw on multiple roles and identities. A professional development program that invites and honors the multiple roles of teachers can expand existing best practices and offer a creative and meaningful response to the reality of remote learning and teaching during the COVID-19 pandemic.

Keywords: play, teacher education, technology-enhanced learning, best practices

Introduction

The COVID-19 pandemic has brought several new challenges to, and highlighted existing inequities within, the educational landscape. School districts are requiring teachers adopt new models of pedagogy, while also fervently working to ensure that each of their students receive the emotional, cognitive, technological, and social support that they need. In many states, teachers are expected to pursue additional professional development opportunities, while, at times, still being expected to care for themselves, children, and family members that live in their homes. The tiilt (technological innovations for inclusive learning and teaching) Fellows Program, which began in 2019, examines the challenges and possibilities for teachers who are caretakers and participants in professional development. At a high-level, the program supports teacher professional development experiences that engage teachers alongside their family members to surface pretty good practices (Erickson, 2014) and highlight ways that family members can be assets to teacher learning.

The tiilt Fellows Program is designed to acknowledge the responsibilities and opportunities associated with caring for and learning alongside family members. Cohorts start during the summer and participate in a one-week synchronous experience alongside other teachers from their school district and any available family members. After the one-week session, for at least a year, participants are invited to regularly meet with the program facilitators and receive support as they implement their ideas from the program. A central objective of the first instantiation of the program was to introduce teachers and their family members to some of the tools found in the Maker Movement and support teachers as they designed new activities for their learners. The teachers that participated in the program expressed clear interest in developing their skills and knowledge of technology based making, and how to incorporate it into their teaching. However, when a summer workshop was suggested, teachers assumed that they could not participate because of their responsibilities as primary caretakers for their children. In response to this, the research team designed a program that would incorporate and encourage intergenerational learning and participation. The program features connections to research on teacher professional development best practices. These practices include being content focused, incorporating active learning, supporting teacher collaboration, using models and modeling, providing expert support, including opportunities for feedback and reflection, and being of sustained duration (Darling-Hammond et al., 2017). We utilize these practices as a base for developing our model of practices for intergenerational teacher professional development experiences. Details about the program design can be found in Perez, Jones, Lee, and Worsley (2020).

Discussion

Within these different practices, there are a few challenges and opportunities that are important to highlight. Specifically, the power of play, which created a low-stakes environment for teachers and their families to learn alongside each other; bridging formal and informal spaces so that participants could workshop their ideas with family members; and, finding opportunities to work with the competing identities of teacher and parent.

The power of play

Play created a low-stakes environment that benefitted the group as they navigated new tools and tested out their ideas. It contributed to general levity that offered moments of meaning and consequence (Hall and Jurow, 2015). Play was characterized by structured or unstructured moments when participants and researchers engaged with each other to maintain interest and productively move ideas forward. At the same time, spontaneous moments of play made group discussions challenging. Some parents felt like their children were too distracting for other participants and would have liked clearer delineations to signal when and where play was appropriate. Play has implications for how teachers might think about learning in the context of home, where the rules of school are less dictated, and students have access to materials that are familiar to them. While the home is different for many, it can be the space where students play and have fun with what they are learning in school. In a time of remote learning, moments or postures of play can offer teachers an opportunity to engage their students and expand what they see as possible for making.

Teacher professional development goes home

We often talk about the importance and value of students being able to explore their learning across contexts, but sometimes forget that this holds true for teacher learning, too. In interviews, some teacher participants shared that having family members participate in the program helped them prepare for in-school implementation in part because ideas and practices in the program crossed over seamlessly into conversations at home. This consideration was factored into the design of the program through assignments and materials given to families to take home and complete before returning for the next in-person session. Furthermore, teachers shared ways they sought to incorporate non-participant family members of the program into the experience. Finally, teachers talked about how the experience was meaningful; having the artifacts at home served as a valuable reminder for the children and teachers of their shared making experience.

Complementary and competing identities

The program filled an immediate need that teachers had as primary caretakers and as teachers interested in making. The opportunity for participants to bring in and enact these two identities together proved invaluable. Teachers emphasized that many existing professional development experiences neglect the different roles that they hold—especially as a caretaker. Hence, there is a need for teacher professional development experiences that intentionally make space for teacher participation and their multiple roles or identities (hooks, 1994). Reconciling these roles, however, presents its own unique challenges. One teacher described her process as constantly having to switch between roles. This may point to an important opportunity for future teacher professional development: providing space for teachers to explicitly discuss their different roles or identities, and how they would like for a given professional development experience to incorporate those roles or identities.

Conclusion

Broadly speaking, the program is an instantiation of what is possible when we reposition something that would traditionally be viewed as a constraint, as an opportunity in teacher learning. We find this a useful paradigm shift in the context of making and the maker movement but suggest that this change might be beneficial across several inquiry- and problem-based learning contexts. The COVID-19 pandemic is forcing the world to deal with a new reality where many of our assumptions are no longer met. Instead of running from these different constraints, we can consider how they might advance new forms of expansive and meaningful teacher professional development.

From "Authentic Tools" to Authenticity: Using CT to Enable Discovery in Statistics Classrooms

Connor Bain, Gabriella Anton, Michael Horn, Uri Wilensky
connorbain@u.northwestern.edu, gabriella.anton@u.northwestern.edu, michael-horn@northwestern.edu, uri@northwestern.edu
Northwestern University, Evanston IL, USA

Abstract: CS Educators pushing to integrate computational thinking (CT) into mathematics classrooms has quickly influenced statistics classrooms where students now analyze data using modern computational tools. Yet while teachers perceive using "authentic tools" in the classroom as providing an "authentic learning experience," the power of computational tools to help reimagine existing content is often overlooked. Our team worked with teachers to co-design two CT-integrated statistics units across two years. We use a model of professional growth to discuss the teachers' changing beliefs over the course of the two co-design projects. We see how the enactment of a programming-focused CT-integrated unit led to changes in teachers' beliefs about the pedagogical impact of CT. These informed the teachers' approach in a second co-design, resulting in a unit that emphasized empowering students to discover statistical concepts via an *authentic learning experience* using authentic computational tools.

Introduction

Prior research has advocated for the integration of CT in K-12 STEM classes with three primary goals. First, the use of computational tools can engage students in authentic inquiry experiences that reflect the work of STEM professionals (Weintrop et al., 2016). Second, prior work shows that students' exploration of computational tools can improve pedagogy and outcomes in STEM as it deepens students' interaction with content (Wilensky & Reisman, 2006; Sengupta et al., 2013; Kelter et al., in press). Third, it broadens access to computing by engaging all students in computational practices within K-12 classes, particularly in the United States, where STEM classes are required and computing classes are often relegated to elective status meaning CT in STEM can reach students beyond those who traditionally take computing courses. Using the interconnected model of professional growth (Clarke & Hollingsworth, 2002), we examine the way that two mathematics teachers make sense of CT within mathematics contexts, and how these conceptions shift through professional development and classroom experience. In this context, we explore the ways that mathematics teachers express their understanding of CT within statistics as they participate in this professional development cycle. How does the enactment of a programming-focused CT unit lead to changes in teachers' beliefs about the pedagogical impact of CT?

Methods

We focus on two participants, both experienced mathematics teachers, from the same high school: Steven and Josh. In the first year of the study, Steven attended CT professional development, called CTSI (Kelter et al., in press), and created a CT-integrated unit with a co-design team. Steven implemented this unit in his class and also recruited and helped his colleague, Josh, to implement the unit with his own students. Steven and Josh both attended the following CTSI where they worked together to build a new unit. It is across these three events, the first PD, the implementation, and the second PD that we examine the changes in the perceived salient outcomes of integrating CT into the classroom for Steven and Josh. We leverage clinical interviews with teachers taken after each CTSI and curricular implementations, classroom implementation video data, and observational field notes collected during the implementations and co-design sessions. We utilize the multiple case-studies method to track the changes in teachers' *personal domain*–their beliefs, knowledge, and attitudes–and how that impacted their involvement in the *external domain* across two PDs centered around co-design and the *domain of practice* (their implementation of the unit). The first two authors coded the teacher interviews according to the IMPG coding scheme, sharing codes and preliminary finds with each other to validate the codes. Video data and field notes from the classroom implementations are used to further triangulate changes in the *domain of practice*.

Discussion and Conclusion

Steven and Josh both originally approached integrating CT for similar purposes of providing students exposure to authentic computational tools (*personal domain)*. They *enacted* this belief system by implementing a computationally enriched lesson focused heavily on the exposure to a new computational tool. Both teachers expressed new ideas about how and why computational thinking should be taught to students (*domain of* *consequence*), suggesting this enactment and subsequent reflection played a large part in updating within their beliefs surrounding CT. They struggled to find a balance between the computational content and the statistics content, first focusing on the computational tool then on the statistics content. They grappled with deciding whether to engage using an authentic tool use compared to using scaffolded computational experiences that more deeply engaged students in the statistics content (see Figure 1). They also noted that these scaffolded experiences did not map to their own conceptions of a math classroom as easily as to the science classroom, suggesting the need for additional scaffolding for mathematics teachers in CT PD. They expressed that it was vital to have the design team present to push back on this statistical focus, and to help frame student engagement around the CT elements (*external domain*). Both teachers expressed a different understanding of CT after participation in the second CTSI professional development but at the time of this work, neither teacher had implemented their second CT-enriched unit, so future work will explore their experiences enacting these new perspectives in the classroom. Broadly, this work contributes to understanding how mathematics teachers conceptualize and approach CT within their domain, with the goal of better supporting computational thinking integration within mathematics and statistics that is more than just exposing students to authentic tools and instead pushes students to engage in authentic practice.

Examining Teacher Reflection in a Multimodal Composition about Identity

Hazel Vega, Clemson University, hvegaqu@clemson.edu
Golnaz Arastoopour Irgens, Clemson University, garasto@clemson.edu

Abstract: This study aimed to examine the reflection and development of a multimodal composition exploring the topic of professional identity formation in a teacher education program of teaching English as a Foreign language (EFL). Using a social design experiment, this study examined the process of a key participant. Three themes were identified: (1) iterations through her composition, (2) critical examination of readings, and (3) giving and receiving feedback. This study contributes to a nuanced conceptualization of reflection through multimodal composition when mediating reflection in identity work in EFL teacher learning.

Introduction

Responding to an increasingly digital landscape in recent decades, shifts in pedagogy have called for more expansive notions of text, giving rise to new forms of literacies (Cope & Kalantzis, 2009). These literacies have moved beyond static ideas of text and writing and have been more inclusive of multimodal forms such as visual and audio (Kress, 2010). This view of literacy is characterized by an agentic construction process of text that integrates multiple dimensions, layers, modes, and stages, positioning the writer as "an active designer of meaning" (Cope & Kalantzis, 2009, p. 175). Research in this area has highlighted the affordances of those expansive notions of text to develop learners' voice, creativity, and meaning-making. Notably, a significant subfield has been the studies on digital multimodal composition, especially with language learners (e.g., Anderson, Chung, & Macleroy, 2018). However, few studies have been conducted exploring multimodal composition with teachers. Although it is a tool with the potential to enhance teacher reflection processes necessary to prepare pre-service teachers, most of the extant literature is related to conventional forms of text such as narratives and autoethnographies. Therefore, the goal of this study was to examine the reflection and development of a multimodal composition exploring the topic of professional identity formation in a teacher education program of teaching English as a Foreign language (EFL) in Costa Rica. The present study describes a full semester-long multimodal project in a language teacher education program, focusing on the intricacies of the multimodal composition process and what made it effective for reflection.

Methods

This research is based on a larger study that uses social design-based experimentation (Gutiérrez & Vossoughi, 2010) to design a semester-long intervention. Participants created a digital multimodal composition telling stories about their English learning experience, process of becoming teachers, and feelings of tensions related to identity development. The participants were fourteen pre-service teachers enrolled in a culture course in an EFL teacher education program in a university in Costa Rica. For this study, one participant, Kathy (pseudonym), was selected because she illustrated the major findings. She strategically selected and analyzed everyday and academic elements to make sense of her lived experiences in her multimodal composition. Data sources for this study included: (1) participant artifacts from iterations of the multimodal composition, (2) a 60-minute interview with the participant to dig deeper into the process she followed in her project, (3) field notes and memos from class sessions and the revision process of the participant's drafts. For data analysis, we iteratively examined the data. Through thematic analysis (Saldaña, 2015), the researcher determined patterns and common themes across the multimodal composition process to identify key moments and elements of the intervention that promoted the participant's reflections on her identity.

Findings

Three themes were identified that facilitated the participant's reflection and development of her multimodal composition: (1) iterations through her composition, (2) critical examination of readings, and (3) giving and receiving feedback.

Iteration through the composing process

Kathy found that revisiting her story multiple times and reexamining the modes selected provided opportunities to further elaborate her analyses and gradually build her modes for meaning-making. For example, by revisiting her experiences and looking for modes, she remembered that she had written the Poem "Mi Lengua No Quiere el Inglés" (my tongue does not want English) in one of her college classes. In this part of her story, she was convinced that she was betraying her culture and language by learning English, so her tongue was rejecting English. This poem's title became a central piece in the mode of this chapter, illustrating her frustration and tension. The iteration process was a scaffolding tool for her to gain deeper meanings of what she was gradually constructing and making effective connections among all the elements and the narration.

Building "aha" moments through critical examinations of course materials

Modifications Kathy made to the modes were connected to specific "aha" moments in the course when students critically examined socialization processes and language beliefs in readings and discussions. An example of this was a reading about a critical autoethnography of a Costa Rican author who had learned English in the same context as Kathy. Because of this critical moment, Kathy included a quote from this reading "My journey started much earlier and can be better understood in the context of sociohistorical local and global dynamics" (Solano-Campos, 2014, p. 422). Kathy decided to tell her story from her perspective. She added audio to explain her feelings and thinking rather than describing the events as they happened. Like the article's author, Kathy owned her story and used her voice to uncover the social and cultural factors not analyzed before.

Giving and Receiving Feedback

During the course, students provided and received feedback through peer assessments and formative revisions from professors. In terms of the professors' feedback, Kathy emphasized that the questions received in iterations of her work guided her reflection. For instance, in the second draft, the professors wrote comments about connecting more with cultural aspects. Thus, she described her first contact with English at the age of five through the interest-driven activity of watching cooking shows. She explained how she enjoyed it as she was unconsciously learning words by association. However, she was not making any connections to culture. After adding the videos and the audio to represent what she was thinking when watching the shows, she decided to highlight in the audio the contrast between the "American dream kitchen" with the "cocina de leña" (wood-burning stove) at her grandma's house. Including this cultural aspect helped her reflect on how she was overgeneralizing that all American homes had that "cooking show" kitchen. The opportunity to receive feedback in key moments of her composition allowed Kathy to construct gradual layers of analysis.

Conclusion

The findings of this study indicate that (1) "aha" moments occurred when unnoticed socialization processes and beliefs about language were critically examined through readings and discussions to provide a tool for interpretation of lived experience, (2) an iterative and recursive approach to multimodal composition to foster deep reflection about the self effectively mediates meaning-making of personal narration, and (3) giving and providing feedback provides distributed and collaborative opportunities for gradual improvement and deeper levels of analysis of lived experience. Altogether, these findings demonstrate that these elements of design assembled to produce a multimodal project mediated nuanced and complex understandings of the self rooted in past lived experience. These results show promise for language teacher education programs aiming to integrate identity work to unravel the mediating power of designing a multimodal composition with the elements of critical reflection, iteration, and collaborative feedback for teacher identity development.

Make with Data: Challenging and Contextualizing Open-source Data with Personal and Local Knowledge

Nathan Holbert, Teachers College, Columbia University, holbert@tc.columbia.edu
Cassie Xu, Earth Institute, Columbia University, cassie@ei.columbia.edu

Abstract: In this poster we describe Make with Data, a two-year project that invites teachers and students from public high schools to work with professional data scientists and open-source data to explore issues important to their local community. While the negotiation of the personal and the quantitative resulted in tensions, Make with Data students found their personal experiences a useful tool for adding context and complexity to the phenomena being studied.

Purpose and significance of the work

In the Make with Data project described here, we engage learners age 16-17, from groups underrepresented in STEM domains, to work together with educators and data scientists in an after-school setting to identify and understand a local community challenge. Leveraging the constructionist design paradigm and research on project-based service learning, the project investigates how framing data science practices as a means of contributing to and improving one's community can impact students' understanding of data and data science practices. By encouraging learners to identify challenges that impact their local community, and supporting them as they use open-source data in collaboration with educators, professional data scientists, and other STEM professionals, students developed a rich understanding of how data can be used to address local needs, which in turn positively impacted their interest in data science related careers.

However, because students have personal experiences related to these local challenges, their exploration of the data inevitably involves negotiating their own perspectives with what they see in the data (Rubel et al., 2017; Wilkerson & Laina, 2018). In this poster we examine how students leveraged their personal experiences in their local community to further elucidate the context and complexity of trends found in open-source data.

Methodology

In the first year of the Make with Data project, teachers were recruited from four boroughs of New York City. Participating teachers were mostly science educators with one pair being social studies teachers. These teachers then selected one to two students from their school to be "student leaders" for the duration of the project.

During this first year, all participants jointly worked through the identification of a locally relevant issue, and in smaller groups set out to explore and find open-source datasets to better understand the issue and propose potential solutions. The teacher and student teams jointly attended approximately 9 sessions with the other teacher-student teams, the project leaders, and professional data scientists. Additional conference calls and meetings between teams and data scientists occurred throughout the year as needed. Full team meetings took participants through a process of brainstorming possible project ideas, learning how to access relevant open-source data, exploring the use of data analysis tools, tinkering with data to explore possible trends, and developing representations and presentations to communicate their findings.

The following year, teacher and student teams implemented a new Make with Data-type project in their own school. Each teacher and student team recruited new students from their school to join their group, developed their own meeting schedules, and—following a structure similar to the one used during the first year of the project—worked with these students to identify and explore locally relevant community challenges. In total, the team (made up of the project leads, data scientists, and students and educators) grew to approximately 50 individuals distributed across four schools.

In this poster we describe the two-year data explorations of two Make with Data students. These cases illustrate the way in which participants' personal experiences with their chosen topic drove their search for data and impacted their interpretation of discovered datasets.

Findings

As expected, students in the Make with Data project took on and explored topics relevant to the experiences and needs of their local community. However, as we will show below, the personal nature of these topics led to an important back and forth between the data, the original research question, and the students' preconceptions.

In the first year of the project, we invited teacher and student participants to consider their own experiences, and those of their community to identify a category of challenges that they would like to explore further. The team from the Bronx chose to focus on student mental health. Speaking about the mental health challenges faced by her and her classmates, Bronx-S (student) stated, “I've experienced mental breakdowns, and I think mental health for students is really important [...] It has affected me because I've had anxiety and stress over school. And that has affected me at home too, my attitude just changes.”

The Bronx team recognized that the geographic layout of their particular borough and school limited access to public transportation so using GIS software, they mapped out the location of mental health facilities, schools throughout the Bronx, and public train and bus lines. However, rather than rely solely on the GIS Data, Bronx-S read her own experiences into the data asserting, “the map and data doesn't tell the whole story” (Van Wart et al., 2020). For example, while there was one mental health facility relatively close to her school, this lone facility served a large number of schools in the area. Furthermore, getting to this facility required overcoming many geographic obstacles—such as moving through areas of high crime—as well as personal ones—like the expectation to come home after school to take care of younger siblings.

Together these life experiences led the Bronx team to build a board game (based on the classic board game “Life”) where players try to make it to the local mental health facility while random events and continually building depression slow their progress. In their project the Bronx team illustrated that access to mental health support is more than just the measure of distance on a map. Rather, their game narrates how a complex interaction of factors—that includes things that can be observed in public datasets as well as factors that are personal, hidden, but no less relevant—impact how students navigate access to mental health support (Wilkerson & Laina, 2018).

Another student, Staten-S, chose to examine marijuana use among teens. While she quickly found relevant datasets, each came with unique challenges and contradictions. For example, when looking at arrest data, Staten-S realized that the NYPD no longer tracks the possession of small amounts of marijuana meaning this data might underrepresent marijuana possession. In Staten-S's words, “not everyone gets caught.” This led Staten-S to examine data on “Stop and Frisk.” She found that incidents of stop and frisk overwhelmingly occurred on Black males (10 times as often as their white counterparts) and showed a miniscule number of incidences resulting in possession charges. Believing this dataset to indicate racist policing policy, Staten-S sought out an alternate dataset, eventually finding a survey on substance abuse. In this survey, more white students reported using cannabis than Black and Latino students. As these results were different than her expectations—expectations that Staten-S admitted were based on problematic stereotypes—she wondered if self-report on a survey could be trusted?

When presenting this work at the end of the second year, Staten-S described the extent of her search and argued that while she had tried to look at this issue from multiple angles using a number of different datasets, “the trends weren't strong enough to come to a specific conclusion.” In the end Staten-S believed the data she was exploring obfuscated things like racist policing practices and data collection methods she wasn't sure she trusted leaving her with “more questions” than answers (Wilkerson & Laina, 2018).

Conclusions

The Make with Data project's central hypothesis is that interest in STEM for underrepresented youth can be substantially impacted by connecting the practice of science with students' personal and communal values and experiences. Through the creation of a learning environment that situates data science concepts and practices in local phenomena and challenges, these two cases show how personal experiences and knowledge about the local context can support data science novices as they make meaning out of complex datasets. While the negotiation of the personal and the quantitative can result in tensions, Make with Data students found their personal experiences a useful tool for adding context and complexity to the phenomena being studied.

Teacher Learning as Co-operative Work to Expand Images of Future Classrooms

Colin Hennessy Elliott, Utah State University, colin.hennessy.elliott@usu.edu
Alexandra Gendreau Chakarov, Quentin Biddy, Jeffrey Bush, Jennifer Jacobs

Abstract: This paper examines the co-operative action (Goodwin, 2018) of teachers discussing research articles as part of a professional development cycle. We make sense of how the articles become part of the interactional resources teachers use to construct images of their future classrooms and students. This has implications for considering the interactional practices of facilitating teacher learning.

Teacher learning is key for developing meaningful changes in science education. This is important as the field grapples with what it takes to realize changes towards science learning that positions students as "*doers of science* rather than receivers of facts" (Miller et al., 2018, p. 1056, emphasis theirs). This paper proposes a form of teacher pedagogy to develop awareness of what teaching and learning science can look like by focusing on teachers' imagined futures. This kind of professional learning activity is a relatively unexplored avenue for promoting teacher learning in design research with untapped affordances. It provides a flexible medium for teachers to shift their vision of their future work that might not be as readily available from watching video or rehearsing practices. It also encourages partnerships between researchers and teachers (Penuel et al., 2020).

This paper analyzes interactions during professional development (PD) workshops which were shifted to remote, synchronous work due to the COVID-19 pandemic. Analysis focuses on how teachers co-construct imaginings of future classrooms during two conversations about science education research articles. Examining how teachers developed their public representations of their future classrooms offers insight into the possibility for this kind of activity to facilitate teacher learning by developing notions of what their classrooms can look like and what their students can do. This is important for imagining more equitable science spaces for students. Our analysis is centered on the following question: *How do teachers' prior experiences interact with new conceptualizations and images of student learning represented in research articles as they co-construct future visions of classroom teaching and student learning?*

Theoretical framework: Developing substrates to change future classrooms

Crafting a future vision of classrooms and students, collectively, is an important aspect of developing teacher "professional vision" (Goodwin, 2018; Sherin & van Es, 2009). Goodwin (2018) describes co-operative action as the social process of "building something new through decomposition and reuse with transformation of resources placed in a public environment by an earlier actor" (p.3). This paper uses the substrate -- or the complex set of resources that teachers bring, decompose, use, and develop -- as the unit of analysis. The substrate is the "immediately present semiotic landscape with quite diverse resources that has been given its current shape through the transformative sequences of action that culminate" in current action (Goodwin, 2018 p. 39). Reading two STEM education research articles as a PD activity reconfigures the substrate teachers use to develop a discussion of their future classrooms and future students. This includes a perspective on how teachers *laminate*, or deploy across modalities and constructs, particular parts of the stories as resources for further social action.

Context and methods

Data were generated during a four-day summer workshop conducted as part of a professional development (PD) cycle with 13 middle school science and STEM teachers. The purpose of the PD was to help teachers learn about, adapt, and enact lesson sequences that integrate computational activities through the use of sensor technologies (Biddy, et al., 2020). The two activities examined in this paper consisted of discussing two education research articles (Manz, 2019; Hardy et al., 2020). We transcribed recordings of both discussions and selected focal clips during multiple reviews (Jordan & Henderson, 1995). Focal video clips were iteratively reviewed and analyzed through multiple passes together by groups of researchers.

Co-operatively positioning future students and classrooms

In reading the second research article, facilitators asked the teachers to focus on the case study of one student, Hope (p. 115-122). The case study presents a shift in Hope's engagement with data as she used sensors to investigate the relationship between plants and CO_2 levels. Teachers were asked to reflect on guiding questions including: "Where do you see opportunities for students to develop agency as they progress through" a co-designed curricular unit. The day began with a discussion of Hope's story, in relation to the teachers' own practice.

Analysis of the following whole group discussion illuminated the varied perspectives that teachers bring to bear on PD sessions and indicated the local substrates as particular and under construction. Each teacher did not just involve their own context but used the locally available substrate to build towards understanding how their future students might: 1) take part in the type of transitions Manz (2019) proposes, or 2) be a data producer like Hope (Hardy et al., 2020). This activity revealed some of the important resources and narratives that teachers deploy to position their future classrooms and students in relation to the ongoing discourse. These included curricula, disciplinary conceptions of science, past experiences with students, and more. For example, one teacher deftly laminated Hope's story onto her experience with science curricula over the past 8 years, from science kits in a box to inquiry driven investigations that get students outside. Two teachers directly positioned their own future students in relation to Hope. One shared "some of my students would automatically be like hope… others would not… you would need to ask good questions," explicitly laminating Hope's story onto her vision of future students abilities, based on her previous experience. She also characterizes the pedagogical move that would support those who need help getting to the level of independent engagement with the scientific processes: asking good questions. The second teacher rejected such a lamination and characterization of the pedagogical need, instead eventually sharing that students would need "certain background knowledge" to do "correct scientific experiments." This contestation is a familiar narrative in science education that characterizes a particular kind of progression for engaging in critical thinking and experimentation: students need certain knowledge building blocks before they can do the experiment, which limits future visions.

Discussion and conclusion

This kind of social action shows persistent, interactional resources that are – and can be – used to laminate the goals of the PD onto the teachers' classrooms and eventual practice. This analysis brings to the fore that teacher PD is not a neutral activity, but an engagement with teacher future visions of their classrooms that are structured and co-constructed from their prior experiences, in addition to other local semiotic resources. The excerpt above exemplifies the possibility of developing teachers' interactional substrates for collectively imagining different futures for their students and classrooms. It also depicts the various ways that teachers inhabit, decompose, and reuse these kinds of visions of futures through what their students will and will not be able to do. Therefore, as we engage sociocultural and constructivist theories of learning to inform curricula designs that are forward looking (Miller, et al., 2018) we must also apply such theories to facilitate teacher learning towards developing what they can imagine future visions of student learning to look like. This paper describes a possible approach as a beginning for considering how to frame more of teacher development intentionally around an engagement with images of future classrooms and students that leaves room for imagining.

Computational Thinking in Preschool: Bridging Home and School

Danae Kamdar, Digital Promise, dkamdar@digitalpromise.org
Shuchi Grover, Looking Glass Ventures, shuchig@cs.stanford.edu
Phil Vahey, SRI International, pvahey@sri.com
Tiffany Leones, Digital Promise, tleones@digitalpromise.org

Abstract: Computational thinking (CT) has received significant national attention as a key skill for all learners. Our research involved working with preschool teachers and families from underserved communities to co-design home and school learning experiences that integrate algorithmic thinking, abstraction, decomposition and debugging. Findings highlight the promise of bridging home and school learning to promote CT and STEM early in childhood.

Computational thinking

Wing (2006) presented CT as "a universally applicable attitude and skill set" oriented towards solving problems and designing solutions, in ways that make them amenable to being solved with computational systems (p. 33). Earlier notions of CT that focused on programming and procedural thinking (Papert, 1980) have since been expanded to include a broader set of skills and practices (e.g., Dong et al, 2019). National attention on CT has led researchers, educators, and policymakers to design CT resources, curricula, and assessments across grade levels. Much of the attention to date has been focused on middle and high school students, with some emerging CT activities and resources designed for elementary children. However, few studies have examined whether and how CT can be promoted in preschool in ways that resonate with young children's experiences and are consequential for early learning. While studies have found that kindergartners can learn to successfully program robots with support, concerns regarding the developmental appropriateness and level of scaffolding necessary for preschool children to successfully engage in these activities have been raised (Kazakoff, Sullivan & Bers, 2013). Researchers have concluded that young children may benefit from engaging in other CT activities that are better aligned to their abilities and interests. A recent study found that preschoolers benefit from learning important CT skills such as sequence, modularity, and debugging during common classroom activities (Lavigne, Lewis-Presser & Rosenfeld, 2020). Preschool teachers are tasked with promoting children's learning in many areas and adding CT into an increasingly crowded curriculum may be challenging. Identifying how CT can strengthen learning broadly and how it can be embedded into STEM areas, such as math and science, is necessary.

Study design and data sources

Our study brings together public preschool teachers; families from culturally diverse, low-income communities; curriculum and media designers; and researchers to engage in collaborative design and design-based research. As part of the co-design process, all stakeholders shared their unique perspectives and insights; brainstormed whether and which CT skills could be consequential for early learning; and collaboratively developed (and tested) classroom and home activities and digital apps to promote CT and STEM. The study consisted of three phases: (1) identifying target content, (2) co-designing and pilot testing preliminary ideas and (3) conducting a small field study to examine implementation and evaluate the promise of designed resources for classrooms and homes.

Figure 1. Co-Design Meeting

Phase 1: Identifying target content

During this phase, the team of stakeholders first came together to identify target content and discuss co-design processes. Algorithmic thinking, problem decomposition, abstraction, and debugging were selected as the initial target skills for the study. A comprehensive list of math concepts and science practices was also generated so that integration could be explored organically as activity ideas were drafted. Using this information, the team generated the first draft of a learning blueprint that served as an anchor document to guide the development and iterative enhancement of resources, as well as the development of research instrumentation.

Phase 2: Pilot testing and Iterating on Design Ideas

Using the draft learning blueprint as a guide, the research team recruited a larger sample of practitioner partners to engage in co-design (2 public preschool teachers and 4 culturally and linguistically diverse families). The co-design team came together four times. During initial meetings, the research team shared "seed" ideas in order to kick off the idea generation process. Teachers and parents shared insights and feedback about the affordances, feasibility and constraints of the seed activities and were invited to generate alternate or/and additional ideas. As ideas emerged, they were entered into the learning blueprint and tagged with the corresponding CT, math and science learning goals. In between meetings, the team tested activities discussed at subsequent co-design meetings.

A total of 22 classroom activities, 6 home activities, and 2 digital apps (for use across home and school) were developed. While we found robust connections between CT and math concepts, connections to science were not specifically tied to core ideas but rather science practices. For instance, algorithmic thinking activities integrated visual spatial skills and counting, while abstraction activities promoted observation and sorting.

Phase 3: Field Study

The final phase included a small field study in 7 public preschool classrooms; 5 classrooms implemented the CT activities and 2 classrooms served as a comparison group. All children enrolled in the classrooms were invited to participate in classroom activities and a subsample of 2 families in each of the intervention classrooms participated in the home-school component. A subsample of 8 children per classroom engaged in a brief CT assessment. Three observations and debrief interviews were conducted with each intervention classroom/teacher and family.

Figure 2. Digital and Hands-on Activities.

Findings from the assessment analysis indicated that the overall difficulty of the assessment items was relatively high for both pre- and post-assessment, with nearly all items having a proportion correct less than 0.5. Most items, however, demonstrated acceptable levels of discrimination. Cronbach's alpha was also found to be reasonably good: 0.72 and 0.78 at pre and post respectively. Assessment data was used to examine improvement in children's learning from pre to post. While the sample is small, significant improvements were detected from pre to post for children who participated in the home-school connection condition, relative to the comparison condition. Interestingly, a significant effect was not detected for children who participated in the classroom only condition, relative to the comparison condition.

Findings from classroom observations indicate that teachers implemented activities throughout the study and appreciated the formats and connections to STEM. Observers noted over 80% of the activities observed were modified by teachers. While most modifications strengthened activities, more than a quarter of the modifications involved excluding CT activity components. It is possible that teachers gravitated toward STEM content they were familiar, excluding content that was new. Successful integration seemed to have occurred when the CT concepts were integral to the STEM lesson and vice versa. Findings from family interviews indicate that families enjoyed the activities and reported engaging in many of them repeatedly with their children. Families appreciated that the activities included experiences they could easily embed into their routines (e.g., grocery shopping, getting ready for school/bedtime) and involved formats familiar to their family (e.g., book reading, cooking, etc).

Transmedia Sensemaking: Working Across Cultural Artifacts to Build Understanding

Katerine Bielaczyc, Hiatt Center for Urban Education, Clark University, kbielaczyc@clarku.edu

Abstract: My research concerns "transmedia sensemaking," how youth work to make sense of phenomena and construct understandings using a variety of cultural artifacts drawn from across multiple platforms and forms of media. I hope to use this poster to invite others to explore this idea and its implication for the learning sciences --- centering the inquiry on a case study of the media-based practices of a young boy over the course of 19 months.

Introduction

Learning sciences researchers have long been interested in what today's rich media landscapes mean for learning. In this vein, my inquiry centers on how youth make sense of phenomena and construct explanations using a variety of cultural artifacts drawn from across multiple platforms and forms of media (e.g., news stories, YouTube clips, films, storybooks), what may be thought of as "transmedia sensemaking." To illustrate the concept, I draw from a case study of the media-based practices of a young boy over the course of several months.

Much of the transmedia research literature focuses on transmedia in entertainment contexts, particularly *transmedia storytelling* (Herr-Stephenson, et al., 2013). I am interested in emergent transmedia collections pulled together into cohesive forms by youth themselves, rather than engineered experiences created by children's media industries. It is possible that these two types may be linked, as youth who are well-socialized into navigating transmedia experiences engineered by children's media industries may be developing a fluency in working across media forms to make meaning. The youth involved in the case study was experienced with popular transmedia experiences, which may have influenced how he used multiple platforms and forms of media for sensemaking.

Context and methodology

The poster centers on a case study of the transmedia sensemaking practices of a young boy, Ronin (pseudonym), over 19 months from ages 9-11. Ronin and I have known each other since he participated in an after-school arts club run by myself and a colleague for local 2nd graders. We re-connected 2 years later and, after learning of his passion for storytelling, I invited Ronin to co-design a storytelling workshop with me. Typically, we meet 1.5 hours/week at either the university or in his family's living room. Both the university and Ronin's home are located in a Northeast urban neighborhood. In our sessions, we explore storytelling through creating our own stop-motion movies, comic books, and other story forms. Over the course of our collaboration, I have been struck by the ways Ronin works across multiple media forms to make sense of phenomena and to construct explanations. In order to begin to understand transmedia sensemaking more fully, I used the audios, computer-screen shots, and field notes across sessions to locate illustrative examples of such sensemaking.

Exploring transmedia sensemaking

In looking across the sessions, a typology of transmedia sensemaking instances has started to emerge. Some of the instances arose as part of our storytelling, some came out of unrelated conversations as we worked together. Below I provide a brief overview of a few transmedia sensemaking types drawn from this initial analysis.

Connecting representations of a concept over time

The meaning making and connections in this example occurred over several sessions, with Ronin raising issues concerning feminist perspectives which he framed in relation to a variety of cultural artifacts. These connections began as we were working on our first story about two friends who are separated then reunited. Ronin underscored the importance of not being like the "typical story" where a prince saves a princess. He told me how, in the animated film *Moana*, the main character saves herself, and that the *The Princess and the Frog* has a very independent princess. He suggested that our story have a boy in distress and a girl saves him. Another day Ronin shared Pixar's *PIRL* on YouTube, where he drew attention to how the relationships between boys and girls "switched." When I asked Ronin what *PIRL* was about, he replied, "Sexism. Because there's 'B.R.O. Capital' and then a girl came." Over time, Ronin has often referred to the need for stories to reflect strong women, which he punctuates with references to Mabel from *Gravity Falls* or showing me a YouTube clip of satirical Disney Princess songs or other relevant YouTube clips. In our planning, Ronin used media forms to back his claims with evidence, and also seemed to be piecing together ideas about gender relations and positioning in narratives.

In-world inquiry into math and science problems

This instance arose with Ronin sharing an interest that he has been developing over time.

Ronin: Do you know for some reason I like, I like these theories. Do you know videogames and, like, movies? They do a bunch of theories on them, there's so much math.

Author: What do you mean math?

Ronin: Like, science and all that, like a bunch of research. Just for, like, videogames and stuff. (Laughs)

Author: So, what's the, give me an example. Like what kind of math?

Ronin: Umm. Like do you know Mario the, like, Tennis Game? …They're seeing if it is actually possible for a tennis ball to break a tennis racquet. And they did it. And it's super dangerous if that actually happened. …And if it was, everyone would die. …So, the ball would move too fast that the air molecules can't move out the way fast enough so there's gonna be an explosion. Same scenario with Sonic, he runs too fast. …If that happened in real life, there'd be explosions everywhere.

In order for me to better understand the reference, we went to YouTube to watch *Game Theory: How to BREAK Mario*! In the clip, the narrator de-constructs the *Mario Tennis Aces* videogame, analysing in-game tennis phenomena through scaling, frame rates, and pixel measurements. The clip is full of sophisticated formulas and computations, which he both deftly and humorously explains through referencing a variety of cultural artifacts (e.g., Sesame Street, real-life TV tennis matches, the Periodic Table) and comparisons to real-life measurement tools. When the clip presented varying computations depending on the type of metal in the racquet, Ronin joked, "He forgot one metal, Vibranium…the strongest metal ever" (a reference to the *Black Panther* movie). The clip engaged Ronin, and scaffolded him in connecting in-world inquiry with problem-solving methods and tools. Although some formulas were too advanced, Ronin had watched the clip numerous times, and followed the reasoning and ways in which math and science could be drawn upon to support investigations.

Co-constructing the Meaning of a Concept

About 8 months into our sessions, Ronin and I worked together to build a shared understanding of "eminent domain." It began with Ronin sharing something he had learned about Disney's *Wreck-It Ralph*: "He was minding his own, if you wait until the very end of the credits, they give you song. It's about eminent domain… It's horrible. It happens to a bunch of real people." We were both familiar with the concept, but did not understand it deeply. Ronin directed me to use Wikipedia, and we read the definition together. He also asked me to find the YouTube channel, *The Film Theorists*, to watch a piece on eminent domain in Wreck-It Ralph that he had found helpful. We also downloaded Pixar's *Up* to see if eminent domain was behind Mr. Fredricksen's loss of property. Not only did the collaboration around the media help in understanding eminent domain, Ronin recognized complexity in a good/bad binary, seeing a character's problematic actions in relation to contexts that felt unfair.

Discussion

Through following his interests in popular media, Ronin is learning how to navigate and build associations between knowledge objects across shared social spaces mediated by digital technology, what Jenkins (2010) refers to as *transmedia navigation*, "the capacity to seek out, evaluate, and integrate information conveyed across multiple media." Ronin's actions in the three examples of transmedia sensemaking indicate that he is developing various epistemic practices and capacities, such as making connections across knowledge objects, pulling together evidence for claims, considering different perspectives, and developing a feel for the use of theories in problem solving. These types of epistemic practices and capacities that Ronin is developing can be seen as assets or resources that may be able to be leveraged into inquiry-based learning. It is important to investigate more deeply the pedagogical implications of making sense in this manner (e.g., Shegar & Weninger, 2010). Further lenses that may prove useful include "objects-to-think-with" (Papert, 1980), learning from multiple sources (Goldman & Brand-Gruwel, 2018), and "conceptual artifacts" in knowledge building (Bereiter, 2002).

Abstract: We describe efforts to use blurred home-school boundaries in the COVID-19 pandemic to co-design learning activities that provide new opportunities for teachers, students, and families to engage with science practices together. This work aims to support the intellectual and cultural resources of home and family life during this pandemic and beyond in ways that draw from and repurpose existing infrastructures**.** We share our design evolution, including commitments, ongoing tensions, and responses to constraints.

Introduction

In this poster, we contribute to work within the Learning Sciences on family-based STEM learning by exploring the opportunities, challenges, and tensions that arise from teachers and researchers co-designing for family learning within formal K-5 educational systems. Specifically, we describe a researcher-teacher team collaboration, within an existing district partnership, that aims to re-imagine a second-grade science curriculum to support opportunities for home-based, multi-age learning that build on families' heterogeneous ways of knowing and learning. We reflect on how the COVID-19 pandemic presented what we took as a set of openings to center relationships, student engagement, and family-based practices as an opportunity for axiological reflection, and potentially innovation, within our work (Bang et al., 2016). Further, we share our design story to explicate how the emerging infrastructure and challenges of remote schooling in our partner district presented stresses, constraints, and tensions that, in turn, led us to refine strategies and structures. We consider this a small-scale case of "infrastructuring," where design includes attention to existing infrastructures and redesigning or repurposing those infrastructures to support new forms of learning and activity (Penuel, 2019). We end by making visible our responses to constraints encountered and our ongoing tensions and questions.

Reorienting our work to new futures

In this poster, we describe how we developed the principles in Table 1 (left column) to orient our team's work and to center learning about the natural and designed world within families, homes, and communities as vital for disrupting injustices in science education (Ishimaru et al., 2015). Our previous work, which focused on co-designing science investigations to center children's resources and ways of thinking (e.g., Manz, 2018), was re-oriented to remote materials development in the summer of 2020 as the COVID-19 pandemic extended school closures. This led to new conversations among teachers and researchers. Teachers found themselves advocating for science to have a continued role in the elementary curriculum, based on their value for student engagement and connection. Researchers, some of us parents, felt called to more explicitly address our commitments to equity and engaging in shifting the narrative of home-based learning from a deficit-based lens towards a partnership between schools and families. Our conversations led us to the left-hand column of Table 1, focusing our design work on the relational aspects of science, increased permeability between school and home environments, family agency, and opportunities for multi-age science engagement.

Constraints and responses leading to new embodiments

As we began to design materials with our team of researchers and teachers and gained buy-in from district partners, our initial design propositions were met with constraints and pushback (Column 2) – stemming, we believe, from the historical infrastructure of elementary schooling and newly emerging pandemic infrastructures of home and school. In response, teachers and researchers have shifted and innovated our practice by repurposing new infrastructures, for example, by utilizing district-wide platforms like Seesaw to invite students and families to share experiences and ideas, rather than using the open-ended menus of optional activities we initially envisioned. In turn, we hope these repurposings will create new infrastructures, such as neighborhood wondering walks and collections of students' photographs that center home experiences for class conversation.

Table 1: Design evolution

Re-Centered Design Commitments	Constraints and Stresses	Embodiment of Commitments in Response to Constraints
Centering the relational aspects of science in our partner district to make science more social, relevant, and connected to students' interests and identities	Teachers have limited time to teach science. There is a district-level discourse around families' limited time and material resources for engaging with science in their home lives.	Teachers utilize morning circle time to create space for science conversations. We prioritize the lessons with the highest pay off for class and family relationality and engagement.
Remote learning increases the permeability between school and home, increasing ways for students' home-based resources to inform instruction and for teachers to see and build on children's various funds of knowledge (González et al., 2005)	Families and teachers are feeling overwhelmed by stresses exacerbated by the pandemic.	We create openings within the pre-existing curriculum for students to share and build upon family-based experiences.
Synthesizing family engagement with scientific practices and learning via optional and fluid activities (Ishimaru et al., 2015)	Teachers, students, and families have a variety of new tools and platforms to navigate. Making activities "optional" is difficult to communicate within existing school infrastructure.	We develop weekly short, open-ended activities, to be shared directly with parents. Recognizing the optional nature of asynchronous elementary-level work, we prioritize activities that are low-stress and high-interest.
Learning in the home environment provides opportunities for families with children of different ages engage in science together, capitalizing on the heterogeneity of families' values and expertise	Schools were hesitant to reorient towards using multi-grade level materials. However, parents have suggested that this is a useful tool for maximizing time and fostering connection.	We design activities such as wondering walks and family conversations that can provide entry points for children of multiple ages to engage with the same scientific phenomenon; including these within the 2nd grade curriculum, rather than the multi-grade materials we had envisioned.

Discussion

We are excited by the way that our work has oriented to newly explicit joint commitments to make science more social, relevant, and connected to students and their families and the opportunity that we (teachers and researchers) have to expand our practices to further recognize and appreciate the resources that students bring to the classroom. We plan to build from these commitments throughout this period of disrupted schooling and beyond. As we explored in this poster, this work to date has involved bringing our commitments into contact with the possibilities of the current system and repurposing the infrastructure for new openings. What we don't yet know is the extent to which our modified designs (e.g., inviting photographs or recorded stories of home objects and practices) will work to disrupt or instead perpetuate inequities within school infrastructures. We hope to engage the community in discussion about the tensions we are facing around the necessity and challenges of working within and repurposing infrastructure to imagine new possibilities for home-based science learning.

Addressing Challenges When Designing NGSS Aligned 3-Dimensional Assessments for Young Learners

Daisy Rutstein, Nonye Alozie, Reina Fujii, Ron Fried,
daisy.rutstein@sri.com, maggie.alozie@sri.com, reina.fujii@sri.com, ron.fried@sri.com
SRI International

Abstract: The National Research Council (NRC) Framework and the Next Generation Science Standards (NGSS) emphasize that all students, beginning in the earliest grades, must have opportunities to learn science. As science curricula for elementary school is being developed, the need for NGSS-aligned assessments increases. This paper describes three challenges (defining assessment targets, gathering desired evidence, and structuring and scaffolding tasks) when designing NGSS standards-aligned first grade assessments and potential solutions to these challenges.

Keywords: assessment design, Next Generation Science Standards, early elementary

Introduction

The Next Generation Science Standards (NGSS, Lead States, 2013) includes science instruction at the early grades (K-2). Including science in early grades instruction has increased the need for science assessments that are appropriate for young learners' cognitive and language development and provides teachers with information about what their learners know and are able to do in science. We describe 3 main challenges when designing NGSS aligned life science assessments for 1st grade and potential solutions to the challenges.

Background

There are many reasons why early childhood assessment is difficult, including the variable and uneven development of young children, differing opportunities young children have to learn, the range of experiences young children have in the real-world, and the propensity of young children to demonstrate what they know and can do rather than talk or write about what they know and can do (The National Education Goals Panel Early Childhood Assessment Resource Group, 1998). Because of such variability, early childhood assessment is typically a multifaceted system comprised of gathering data using different methods such as observations, interviews, and portfolios (Slentz, 2008). Little literature on design principles (Scott-Little & Niemeyer, 2001) or frameworks to design early childhood assessments can be found, especially in science. Designing for early elementary students should include opportunities for students to engage with science concepts using tasks that are appropriate for students at different developmental stages. Currently there is little guidance on how to design assessments that target science learning, and cognitive or language development of young learners. We describe our approach to addressing challenges in designing a 1st grade science assessment task for performance expectation (PE) LS1-1 "Use materials to design a solution to a human problem by mimicking how plants and/or animals use their external parts to help them survive, grow, and meet their needs".

Challenge 1: Defining measurement targets

The NGSS performance expectations (PEs) are 3-dimensional, with each PE incorporating disciplinary core ideas (DCI), science practices (SP), and cross-cutting concepts (CCC). While the DCI tends to differ between grades, the SPs and CCCs are shared across grade levels. A challenge was identifying the grade level boundaries for these dimensions and developing measurement targets that specify how the SPs interact with the DCI and CCC in a way that was developmentally appropriate for first graders. For example, for PE1-LS1-1, we used drawings and written descriptions to address the CCC and narrowed the DCI to focus on animals that are familiar to first graders. The resulting measurement target for PE 1-LS1-1 was (italics added for emphasis) "Ability to design a solution, through *drawing and/or describing*, to a given problem that is based on *a familiar animal part* that helps that the animal survive, grow and/or meet its needs."

Challenge 2: Gathering the desired evidence

Determining how to gather appropriate evidence can be challenging because 1st grade students have varying levels of oral language competency, word reading ability, and writing proficiency. Additionally, our assessments were limited to the paper and pencil format, making tasks that require skills in designing solutions challenging. Since we decided to allow students to express their understanding by integrating drawing and writing modalities as their responses, gathering student evidence involved examining and interpreting student drawings and determining how well their drawings aligned to the PE. Evidence of proficiency focused on the extent to which the design was related to the animal body part that the students identified and whether or not their design would be an appropriate solution to the human problem. We also analyzed how well the descriptions of their drawings articulated a solution to the human problem. Student textual descriptions were scored for students' intentions behind the description rather than grammar or spelling.

Challenge 3: Determining the structure of tasks and amount of scaffolding

Another challenge was to determine how to structure each task including the degree to which and the type of scaffolding to provide support to students when engaging with the assessment task. In one-on-one administration, alternative prompts are often developed in case students are unable to respond to the initial prompt. This type of structure is not available in an assessment that does not respond to individual students. Our design process addressed this challenge by examining the task and determining 1) the information students need to answer the questions, 2) whether students need all of the information at once or if the information can be broken up to help students focus on the goal of a particular question, and 3) how questions can be organized to walk the students through the question without giving away the responses.

For PE 1-LS1-1, students were asked to design a solution, modeled after an animal body part that can reach an object that was far away (i.e., high above the head). For this task, students were given 3 options of animals: a bird, a giraffe, and an elephant. We used animals that we believed most 1st graders were familiar with and allowed students to pick the animal that could serve as a model for their design solution. Giving students choice increased the chance that students would be familiar with the animal and subsequently design a solution that aligned with the animal. We represented each animal in the motion of reaching for an object that was high in elevation to support students in making the appropriate connections between the animal and their design. The task asked students to draw a circle around the body part that the design solution would be modeled after to help students focus on their design features. We allowed students to provide written responses in addition their drawing to allow multiple opportunities for students to express their developing proficiency.

Discussion

Addressing challenges related to language development, literacy skills, and the developmental stage of students can inform the development of 3-dimensional NGS aligned assessment tasks, the associated rubrics, and the nature of the administration prompts and scaffolds. Developmental characteristics of early learners are attended to throughout the design process in order to ensure the assessment tasks are developmentally appropriate. While this type of process is critical for any grade range, explicitly laying out what is required of students in terms of their language and literacy capabilities is particularly important at the early grades. Recognizing that there is a range of abilities in classrooms and highlighting ways to ensure that everyone can engage with the task will help ensure that students are able to demonstrate their proficiency related to the PE. The resulting assessment scores will be a more accurate portrayal of student's science ability and not a measure of their ability to read and write.

Students' Dynamic Framing of Epistemic Agency

Jason M. May, University of Utah, jason.may@utah.edu
Lauren A. Barth-Cohen, University of Utah, lauren.barthcohen@utah.edu

Abstract: Learning environments are socially shared cognitive spaces where students can act as *epistemic agents*. This case study explores how students mutually frame opportunities to enact epistemic agency in a group-based laboratory setting. We show how an undergraduate student group frames epistemic agency within course constraints but maintains ownership of the collective group frame's negotiation and reproduction via individual discursive and active contributions. Results suggest students can maintain a collective group frame of epistemic agency in a learning environment, even when students offer distinct frame contributions.

Theoretical background and methodology

Scientific inquiry learning environments allow students to collectively and actively engage in scientific experimentation to generate new knowledge through a socially shared cognitive context. In these contexts, students are meant to act as *epistemic agents*, or "individuals or groups who take, or are granted, responsibility for shaping the knowledge and practice of a community" (Stroupe, 2014). Epistemic agency is thought to exist inseparably between the individual and the utilized mediational means, such as discourse, apparatus, and sociocultural norms (Wertsch, 1993). As learners experience significant shifts in learning environments that now expect greater levels of enacted epistemic agency, it is essential to understand how learners generatively perceive and interpret their learning environment as a shared space to enact their epistemic agency. This study focuses on how students collectively contribute to a group's framing of epistemic agency within a socially shared setting. Specifically, we present a case study of four students engaging in a group-based physics laboratory investigation, exploring their mutual framing of epistemic agency within the course structure's constraints and expectations.

This study focuses on four students, Lacee, Ethan, Mika, and Caroline (pseudonyms), who engaged in an undergraduate introductory physics for life sciences (IPLS) laboratory course. This course's primary learning goal is to productively engage students in complex scientific practices while interacting and sensemaking with interdisciplinary concepts. The course in question emphasizes epistemic agency by: a) giving students freedom to develop their own investigative questions and experimental methods; and b) training teaching and learning assistants (TAs and LAs) to empower students to be epistemic agents in their investigations. The presented data comes from the group's third multi-week investigation in the course; each student previously worked with at least one of their current group members. To investigate students' framing of their epistemic agency through a mediated lens, we employ frame analysis (e.g., Goffman, 1974) to study: a) the discourse and associated action involved in student investigation and how this contributes to the development of a collective group frame in light of larger sociocultural processes; and b) how continuing discourse and action from participating individuals sheds light on their contributions to and changes of the collective group frame. We first sought to identify the collective group frame's outer boundaries and thereafter explore individual student contributions to the group frame (Steinberg, 1998). We note our view that frames exist between individuals, rather than within them individually, with each individual uniquely but mutual-dependently contributing to the collective frame. (Medvedev and Bahktin, 1978).

Dynamics of and within collective group frame

Via initial introductory material and direction from the TA, the course structure sought to impose a preliminary framing of epistemic agency (e.g., TA: "These are just possible options… we definitely want your groups to come up with something unique and something specific that you want to study."). The course and instructors "primed" students to frame their investigation as an opportunity to enact epistemic agency without assessment/criticism from TAs/LAs but within the larger course structure (i.e., consistency with scientific topics and experimental apparatus). In response, the group mutually developed a collective group frame within these implicit constraints; for example, through discursive moves, the group explored potential research questions that accounted for the lab's guiding prompts and available apparatus. During this discourse, students incorporated external scientific phenomena that resided outside the course material rather than attempting to unearth and utilize conceptual or procedural information from lab documentation, a common practice in laboratory settings. When interacting with the TA, the group asked clarifying questions about apparatus and course requirements but did not ask for prescriptive steps or affirmation of their methods, suggesting they were framing the learning environment as permitting them to be the main epistemic agents in their experiment. This highlights how the group collectively developed a collective group frame that resided within the course's implicit constraints on epistemic agency.

Though a collective group frame was developed, distinctions between student involvement arose; for example, while Lacee, Caroline, and Ethan engaged in active dialogue to develop potential research questions and experimental plans, Mika asked questions more dependent on other group members' enacted epistemic agency (e.g., "So what's gonna be our [research question]?"). Mika's framing of the group's ability to enact epistemic agency resided within the constraints defined by the course structure and initial introduction and maintained by the group, in that she understood the need for the group to enact its collective epistemic agency to conduct their experiment but seemed reluctant to personally enact her epistemic agency within the group. Though this and other distinctions arose, they did not significantly impact the group's experimental trajectory, instead potentially providing additional opportunities for the group to enact its collective epistemic agency to initiate experimental progress. The discourse resides between Mika and her group members and mutually benefited both parties; Mika gained further understanding of the experimental methods, and the collective group having additional opportunities to enact epistemic agency by discussing experimental details and future progress.

During formal experimentation, additional distinctions arose between group members. For example, Lacee gravitated towards the procedural aspects of experimentation, making decisions on setting up and using experimental apparatus to generate experimental results. In contrast, Ethan consistently brought conceptual topics and questions to the group to explore what conceptual knowledge was necessary to connect their experimental results to external scientific phenomena. These examples suggest that Lacee and Ethan both framed the learning environment as providing significant freedom to enact epistemic agency, though they individually chose how to enact it. Caroline and Mika exhibited more passive perceptions of their opportunities to enact epistemic agency. For example, Caroline framed her role as one of support and revoicing of Ethan's conceptual ideas and Lacee's experimental methods, and Mika frequently asked self-clarifying questions about experimental methods and concepts. Noteworthy in their contributions to the group's experimentation is that, though they did not often enact their own epistemic agency explicitly, they maintained (and even sometimes bolstered) the group's collective epistemic agency. This is in stark contrast to potential alternative outcomes, such as a clash in individual perceptions of the learning environment, which could result in reformation of the collective group frame away from epistemic agency and towards authoritative dependency, as often occurs in laboratory settings.

Discussion

The above vignette shows how a group of undergraduate students in a group-based physics laboratory course developed and maintained a collective group frame that resided within the course's intended framing of epistemic agency, even when students maintained unique roles and individually contributed distinct, and sometimes contested, discourse and action to the collective group frame. These results suggest that students can effectively maintain a collective group frame of epistemic agency and learning within an agentic instructional approach, even with distinct and unaligned individual contributions. This study adds to literature suggesting inquiry-based STEM environments can enhance student enactment of epistemic agency, but results show the nuance of individual distinctions in student contribution to the group's collective framing of epistemic agency (Miller et.al., 2018).

Investigating Teacher Data Needs In Terms of Teacher Immediacy and Nonverbal Behaviors

Franceska Xhakaj, Amy Ogan, Na Young Lee, Erik Ulberg, Amy Luo, Seoyoung Lee, Katrina Hu
francesx@cs.cmu.edu, {aeo, nlee1, eulberg, awluo, seoyounl, kfh}@andrew.cmu.edu
Human-Computer Interaction Institute, Carnegie Mellon University

Abstract: Teachers play a crucial role in students' learning. Therefore, it is important to support teachers in their teaching practice. In particular, it is important to support teacher immediacy which is essential to improving learning and creating a positive classroom environment. We describe an exploratory study aimed at understanding teachers' immediacy data needs. Teachers showed interest in such data about themselves and their students. We discuss how teacher immediacy data can help teachers in their practice.

Introduction

Teachers are crucial in supporting students' learning, making it essential to support teachers in their practice and help them improve their teaching. Professional development (PD) is a typical way to provide such training. PD is highly effective (i.e., Avalos, 2011) but can often be repetitive, not personalized, not scalable and infrequent (Hill, 2009). PD also often overlooks teacher immediacy, an important aspect of teachers' classroom skills. Teacher immediacy involves the nonverbal behaviors that reduce physical and/or psychological distance between teachers and students and increase their interpersonal closeness, with the ultimate goal of enhancing student learning (Andersen & Andersen, 2008). Examples of nonverbal behaviors include location, movement, eye gaze, smiles, nods, posture, gestures, etc. Prior work has shown that teacher immediacy and nonverbal behaviors have a positive impact on teaching, learning and on creating a positive and inclusive classroom environment (i.e., Andersen & Andersen, 2008; Witt et al., 2004). It has been extremely challenging to collect data on such features (i.e., teacher gaze during class or students' gaze over the semester) to use in PD, even with professional observers. Recent advances in instrumented classrooms (i.e., Ahuja et al., 2019) enable opportunities to easily collect a variety of nonverbal immediacy data and provide teachers with personalized and scalable feedback. Literature shows that when teachers view classroom data, it helps their practice and they significantly change their teaching practices (i.e., Xhakaj et al., 2017 a; b). Here, we report on an exploratory study to investigate teacher data needs in nonverbal immediacy behaviors as a step towards supporting teachers' classroom practice.

Methods

We recruited 8 instructors and collected video data for 3-9 classes per instructor using the EduSense instrumented classroom (Ahuja et al., 2019) during the Summer 2019 semester at an American university. We then scheduled a 1-hour semi-structured interview with instructors; they were compensated $15/h. We paired the interviews with PD modules on immediacy, and visualizations (Figure 1) that presented teachers with a subset of data collected from their course with EduSense. The visualizations aimed to start a conversation with instructors and engage them in a discussion around immediacy, nonverbal behaviors, and data they could envision wanting or needing. We transcribed the interviews and conducted a thematic analysis.

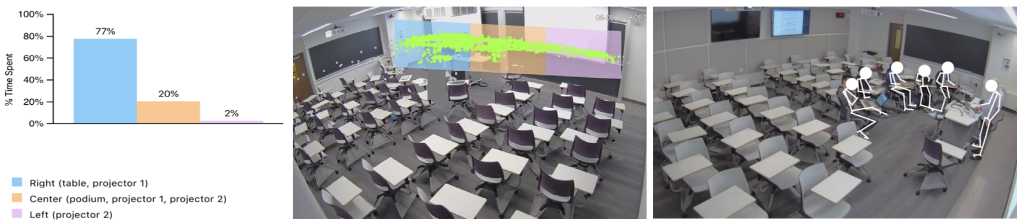

Figure 1. Examples of the visualizations shown to teachers.

Findings

All teachers expressed interest in various immediacy and nonverbal behavior data. Teachers expressed strong interest in their own data. They wanted to know location and movement data including what activity they were conducting at the front of the class, i.e., were they writing on the board, lecturing in front of the projector, etc. (1). Teachers also wanted to know their distance from the board (1), were they sitting or standing (1), their proximity to students (1), and how students were distributed in class, to determine where they need to spend more time (2). Half of the teachers (4) were interested in their eye contact and gaze. For example, one teacher was interested in how often they face their class, while another was interested in having egalitarian eye contact with students. Teachers were also interested in posture data such as were they standing straight and showing enthusiasm (1), how their body language differed based on the activity (1), and whether they had egalitarian physical engagement with students (1). One teacher was interested in how much they smile, and another was interested in gesticulation synchronized with speech. Lastly, two teachers were interested in metadata such as gender or age: how this plays a factor on whether they stood behind the podium or in front of the class (1), and the other, on how this differentiated the kind of interactions they have with students or indicated any biases in those interactions.

Further, all teachers were interested in student data. Specifically, they were interested in different aspects of student engagement, attentiveness, and focus during class. For example, 3 teachers were interested in students' engagement in relation to devices, such as phones or laptops. Teachers thought these devices sucked students' attention from class. Another teacher was interested in the "back and forth" they had with their students, while two teachers were interested in student eye contact data. Two teachers wanted to know about students' body position, as a proxy for engagement. Specifically, they wanted to know if students were slouching or if they were leaning forward on their computers, if they were writing and how much they were taking notes, especially when it was unprompted by the instructor. One teacher wanted to see student leg positions as a way to tell if any of the students were completely closed off in their physical interactions.

In addition to student data, teachers were interested in "student reaction data", namely how students react to teacher actions in class. Teachers thought that this kind of feedback could help them gauge how effective their own practices were. For example, if they stood at a certain location or if they used certain gestures, would that help them reach their goal of increasing student engagement? Two teachers were interested in how student attentiveness, engagement and gaze is relative to where the teacher is standing in class, and how students' body positions change when the teacher moves around in class. Another teacher was interested in how the imbalance in their position in class affected their students, in particular if that caused them to be less focused and inattentive. Similarly, another teacher was interested in the effects of smiling on student attentiveness. Lastly, one teacher was interested in knowing how different students react differently to their actions

Discussion and conclusion

In this paper, we describe an exploratory study to investigate teacher data needs regarding immediacy and nonverbal behaviors, and to better understand how such data can support teachers in their practice. Findings showed that teachers valued immediacy and nonverbal behaviors and were interested in data to support their instruction and improve on their practices in these areas. Teachers were interested in data about themselves, their students and how their actions affect their students in class. In particular, teachers wanted to use this data to keep and increase student engagement and to create a more equitable classroom environment, by sharing their time and attention equally among all students. These results show that there is value in providing teachers with data and feedback on both teacher and student classroom behaviors. In our future work, we aim to design technologies that will help teachers reflect on their immediacy and nonverbal behavior data to support their classroom practice.

Early Childhood Cross-Topic Interest Development in STEM

Amanda Barany, Drexel University, amb595@drexel.edu

Mamta Shah, Elsevier Inc., m.shah@elsevier.com

Abstract: Research is needed to examine ways in which young learners explore and develop interests in everyday environments. This study applies Azevedo's lines of practice research to conceptualize Mihir's (pre-K to grade 1) participation in 'A Bedtime Curiosity' (ABC) with his mother, during which he asked questions and expressed topic interests, then co-explored possible answers and engaged in discussions. 162 questions were coded for interest topics to highlight patterns of cross-topic questioning. Results offer preliminary insights into what interest topics emerged as dominant or were backgrounded, residual, transitory or potentially unexplored by Mihir, contextualized by qualitative researcher memos of the ABC experience.

Introduction

Models of interest development have emerged as a way to encourage learner exploration of science topics (e.g., Hidi & Renninger, 2006) but such models of interest and motivation may not account for the complexity of a young learner's cross-topic exploration, particularly as it unfolds in unstructured settings. Research shows children (2-10 years) engage in domain-specific inquiry and engagement through everyday family activities (Keifert and Stevens, 2019). Given the paucity of research on young children in the learning sciences, further research is needed on how to encourage and assess early childhood interest development in informal learning settings (Tippett & Milford, 2017). We attend to these gaps by examining a family engagement routine involving scientific thinking and content. Shah and her son Mihir (pseudonym) participated in 'A Bedtime Curiosity' (ABC) (designed by Shah) a nightly activity in which he expressed an idea he was curious about, asked a question, co-explored possible answers by watching a short video, followed by a discussion if requested. We examine, *"In what ways did a child's cross-topic interest in STEM develop over time (preK-grade1) as he engaged in a bedtime reading and inquiry routine?"* This research applies Azevedo's (2011) research on lines of practice as a way to understand the complexity of interest development that manifested in Mihir (pseudonym) over time as he chose topics of inquiry as part of his nighttime ABC routine. The lines of practice framework provides theory-driven language to contextualize Mihir's within-topic and cross-topic trends of interest development.

Methods

When the author's (Shah) son Mihir was almost 5 years old, she began *a bedtime curiosity* (ABC). During ABC, the pair read two books, and then Mihir was encouraged to express an idea he was curious about, ask a question, and explore possible answers with his father or mother (Shah) by watching a short video (3-7 mins), followed by discussion if requested. For details on ABC, see Shah and colleagues (2020). During ABC, every question Mihir asked was logged chronologically, amounting to 162 questions across two data collection periods: Pre-K (November 2018-September 2019) and Grade 1 (September-November 2020). Shah created memos to document question contexts, such as descriptions of holidays, current events or recent activities that may have shaped Mihir's inquiry. Memos also recorded resources accessed and discussion topics that emerged from each inquiry.

We conducted a thematic analysis (Corbin & Strauss, 1990) of the questions to generate codes that represent the topics in which Mihir expressed interest: chemistry, zoology, meteorology, geology, paleontology, biology, history, games, anatomy, engineering, and astronomy. Questions were then coded for the presence (1) or absence (0) of a topic for each content using social moderation across two raters (Herrenkohl & Cornelius, 2013). Results are presented as a qualitative case study structured by Azevedo's (2011) lines of practice work, including: a) interest *dominance* (more frequent engagement), b) interest *backgrounding* (less frequent engagement as other topics take prominence), c) *residual* lines of practice (topics he has exhausted but returns to periodically) d) *transitory* lines of practice (i.e., one topic that is subsumed another, larger topic), and e) *potential* lines of practice that he might explore if social norms and designed features of the ABC routine were different.

Results

Mihir asked back-to-back questions regarding bodily processes (i.e., how is pee formed?) in the first few weeks of ABC, suggesting *dominance* in anatomy in biology. Dominant interests then shifted toward how different items were engineered or manufactured (i.e., colored pencils, houses). Memoing regarding these processes revealed that Mihir mostly asked biological questions about processes he regularly experienced, and engineering questions about interest objects he noticed in his household or at school. Questions related to astronomy on the other hand, which were initially more *backgrounded* in comparison to engineering, quickly rose in dominance as a topic he returned to more frequently and with increasingly detailed inquiries. Astronomy interests also manifested in the choices noticed by Shah, including viewing space-related media and creating relevant stories, art, and 3D models.

Mihir's engagement with engineering may serve as an example of a *residual* line of practice; memoing revealed a point at which he could no longer think of questions related to how objects were manufactured or engineered. At Shah's encouragement, Mihir began exploring more diverse lines of questioning but would often return to the occasional "how is this made" question as new contexts inspired them. For example, Mihir asked how monster trucks were made after his mother described a local monster truck event. Several topics in Mihir's inquiry remained *background* lines of practice, such as questions about geology and meteorology. These topics might serve as examples of *transitory* lines of practice that were subsumed by the more dominant topic of astronomy; forays into geology and meteorology were often related to processes happening on Earth, which may have connected to Earth in the wider context of space. At one point, Mihir asked "how hot is lava?" followed by "what is the biggest star there is?" suggesting he may have seen connections between these topics.

Zoology and paleontology topics remained *backgrounded* throughout Mihir's exploration. A question coded for games ("what is the weakest Pokémon?") offered insight into a *potential* line of animal-related inquiry that might have been further explored under different circumstances. Shah reflected that Mihir would routinely engage in activities outside of ABC that suggested interest in fantastical animals, including scheduling virtual discussions about Pokémon with his friends. Shah noted that Mihir asked her a few questions about Pokémon but ceased after she explained her lack of expertise. Perhaps as a result, Mihir's ABC questions about animals were restricted only to animals that once existed or currently exist. Unconscious social norms of the household may have encouraged Mihir to emphasize real-world science and engineering questions, as both parents are scientists.

Discussion and Conclusion

Results highlighted the complexity of Mihir's cross-topic interests over time, such as how topics emerged as dominant over time (i.e., biology first, astronomy later), how he residually returned to others (engineering), and others were potentially subsumed under astronomy (i.e., geology) or remained as potential only (fantastical animals). This routine also shows how a mother fostered her child's engagement in structured lines of practice. The National Research Council reports on science education have discussed how children of preschool and elementary school age demonstrate readiness for science (2012), but further research is needed on mechanisms and practices that can promote deep curiosity, and how interests and motivations shift as a result. Potential limitations include the design of ABC and Mihir's social context, which may have encouraged the exploration of some topics over others. Future work will qualitatively describe and analyze Mihir's questions and consider the potential role of daily events, including Mihir's activities when ABC was not in place.

Integrating Immersive Technology into Small Group Learning Environments

Taehyun Kim, James Planey, Robb Lindgren
thk4@illinois.edu, planey@illinois.edu, robblind@illinois.edu
University of Illinois at Urbana-Champaign
Jina Kang, Utah State University, jina.kang@usu.edu

Abstract: The goals of this study were to explore (a) whether students learn critical STEM content through group activities that integrate immersive virtual reality (VR) with more traditional digital simulations, and (b) whether choosing to use VR affects students' learning and their perceptions of the activity. The results indicate overall improved pre-post learning outcomes for students in multiple sections of a college astronomy course who participated in the multi-device activity.

Introduction

Technologies such as large multi-touch display surfaces have been shown to be effective for facilitating collaborative learning (e.g., Mercier & Higgins, 2013), but immersive technologies such as augmented reality (AR) and virtual reality (VR) are assumed to have more utility for individual learners and have been used less frequently for collaborative tasks. Numerous studies in recent years have shown that using immersive technologies to alter student perspectives with digital overlays and simulated environments can improve individual learning outcomes in a range of learning domains (Checa & Bustillo, 2020; Concannon et al., 2019; Ibáñez & Delgado-Kloos, 2018). What has been less explored is whether single-user immersive technologies such as VR can be integrated productively into a small group learning activity involving other technologies with different students adopting different perspectives and taking on different roles.

In the current study we looked at a collaborative learning task situated in an undergraduate introductory astronomy course. Students who worked on this task were given many resources including tablet computers and a single VR headset that all tapped into the same set of star models, but with each technology having different affordances for exploration and perspective-taking. The goal of this preliminary study was to understand: (1) Do the individual students participating in this task learn the desired content? (2) Is the amount of time spent using the VR related to the subsequent learning outcomes? (3) Is the amount of time spent using the VR related to the students' attitudes toward the learning task?

Software environment and the tasks

The software enables group members to share observations and annotations of the night sky across both VR (Oculus Quest headsets) and tablet PCs (Microsoft Surfaces) while maintaining a consistent interface and representation of the night sky. Three main views are provided within the software: star view, horizon view, and Earth view (see Figure 1). Horizon view allows for the observation of the night sky from a specific location, date, and time. Earth view allows observe the Earth from above while dropping pins to change their location and obtain latitude and longitude coordinates. Star view provides an explorable view of the full celestial sphere and catalogued western constellations.

The task "Lost at Sea" has students using their observations of the night sky to determine the location of a crewed space capsule that has splashed down at night somewhere on Earth. Groups of students must first identify features of the night sky to determine which hemisphere the capsule is located in (Task 1), then identify familiar constellations to use as reference points (Task 2), then refine their location estimation through the calculation of both latitude (Task 3.1) and longitude (task 3.2) using the night sky.

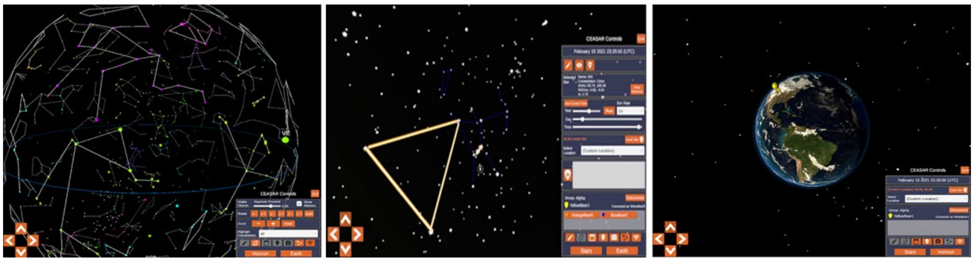

Figure 1. Star view (left), Horizon view (center), Earth view (right)

Participants and measurements

The participants were 33 college students recruited from a subject pool at a community college in the mid-western United States. All students were taking the same introductory astronomy class and were asked to voluntarily form a group of three to four students to work on the tasks collaboratively. Most of the groups spent about 60 minutes to solve the tasks together. One VR and two tablet devices were provided to each group and a pre/post-test and post-questionnaire were completed individually by all participants in the study.

The paper-based materials consisted of a pre/post-test and post-questionnaire. Pre/post-tests were conducted to measure changes in students' knowledge of the procedures involved in calculating latitude and longitude based on the night sky. The question asked in both tests was the same: "Write as much as you know about the steps for calculating latitude and longitude based on the stars visible in a given location." The tests were scored for correctness and complexity on a 0 - 2 scale. All scores were calculated independently by two research personnel and the results were exactly consistent with each other. In addition, the post-questionnaire asked students to make self-ratings on a 5-point scale of statements of perceived difficulty for each task and statements of evaluating the VR simulations. It also contained a short-answer question about how long they had used VR.

Results

For the *first research question*, Wilcoxon signed rank test was conducted on the pre- and post-test scores of each student and the result shows that there is a significant difference in the means from pre- to post-tests, with gains for both latitude ($W = 153$, $Z = 4.07$, $p < .01$, $r = 0.71$) and longitude ($W = 45$, $Z = 2.99$, $p = 0.01$, $r = 0.52$). For the *second research question*, a one-way ANOVA revealed no significant differences for both latitude and longitude, but weak negative correlation has been found for latitude (-0.22). In addition, a simple linear regression was calculated to predict perceived difficulty based on the time spent on VR found that the longer students used VR devices, the more difficult they perceived Task 1. For the *third research question*, a simple linear regression was conducted. As summarized in Table 1, the results showed that the longer students use VR, the more positive they evaluated the VR simulation experience.

Table 1: Students' rating of VR simulation

Post-Questionnaire Item	F	*p*	Correlation
"The VR simulation was useful in completing the task goals"	3.97	0.06	0.34
"I would like to learn with VR in the future"	3.98	0.05	0.34
"I felt happy while using the VR simulation"	6.83	0.01*	0.42
"I felt excited while using the VR simulation"	7.37	0.01*	0.44
"I felt bored while using the VR simulation" (reverse scored)	7.09	0.01*	0.43

Discussion

We acknowledge that having a small number of participants and the absence of a control group are limitations. However, the evidence of overall positive learning outcomes measured via the pre- and post-knowledge assessment indicate that individual students extended their existing astronomy knowledge while engaging with novel technologies and modes of interaction. Significant correlations of time in VR with self-reports of positive affect support the role of VR as an engaging tool in the learning process for this set of astronomy tasks. In addition, the perception of increased difficulty for Task 1 for those spending more time in VR, but not for Task 2 or 3 may be an indication that acclimating to the novel technology environment could be impeding initial learning. To address this, revisions of both the task and the software to provide appropriate and timely scaffolds that assist the learner with using the immersive environment will be critical to ensure productive collaboration and learning.

Peeking into the AI Hype: Investigating Research Trends and Collaboration Dynamics in Artificial Intelligence in Education

Yipu Zheng, Jie Chen, Zhuqian Zhou, Zach Friedman, Paulo Blikstein
yipu.zheng@tc.columbia.edu, jc5230@tc.columbia.edu, zz2404@tc.columbia.edu,
zjf2003@tc.columbia.edu, paulob@tc.columbia.edu
Teachers College, Columbia University

Abstract: This project presents an in-depth analysis of the dynamics of the International Artificial Intelligence in Education (IAIED) Society through co-authorship networks and keyword analysis, discussing its implications to the larger research community. In addition, this study provides methodological contributions to the analysis of author and topic networks within multidisciplinary communities such as the Learning Sciences.

Introduction

With the growing attention to Artificial Intelligence (AI) in recent years, the application of AI technologies to education followed: AIED has been developing rapidly as an interdisciplinary research area (Feng & Kirkley, 2020). But the development of AI-powered content delivery systems, personalized learning management software, and adaptive testing platforms has been much faster than the growth of the research community (Zawacki-Richter et al., 2019). Now propelled by the global pandemic and remote learning, the AIED technologies might impact millions of students, teachers and schools all over the world at an unprecedented speed. Such significant implications of AI in Education (AIED) leave researchers and research communities with greater responsibility than ever to examine strengths and weaknesses, risks and opportunities, and costs and benefits of implementing AI in various learning scenarios. As the AIED field was growing, so were the calls for closer examination of issues of ethics and social justice around AI (Zuboff, 2015; Berendt et al., 2020). In particular, the International Artificial Intelligence in Education (IAIED) Society, as one of the earliest and more well-defined research communities in this area, has been viewed as an important leader in conversations around AIED. Given such a context, this paper aims to present a bird's-eye view of the recent research in this field through social network analysis on co-authorship networks in the community. The study is guided by the following research questions, which attempt to examine how the field is prepared to navigate itself in a world in which it has a critical social responsibility:

1. What are the major topics and interests in the IAIED research community (2013-2020)?
2. Is the IAIED research community open to new topics and new members, and attuned to new societal concerns?

Methods

To address our research questions, we analyzed time-evolving co-authorship networks and keyword usage trends of conference full papers from the International Conference of Artificial Intelligence in Education (ICAIED) and journal papers from the International Journal of Artificial Intelligence in Education (IJAIED) published from January 2013 to October 2020. The data were retrieved from Springer and the IJAIED official website. We collected the links of the web pages of target papers, automatically accessed the website's source code, stored the source code as text files, and then used *BeautifulSoup* library to extract data from the source code. The dataset contained 949 articles from 1915 authors from 2013-2020, and included the following fields: article title, author names and affiliations, publication year, keywords, abstract, and references. Full body texts of articles were also retrieved for further research.

In our data analysis, we examined the overall trends of topics from 2013 to 2020 through the most frequently used keywords, ascending keywords, and descending keywords over time. Additionally, we built time-evolving coauthorship networks with a two-year sliding window and utilized them as a proxy for the evolving collaboration network of the IAIED community. Core members of the community were identified using degree centrality. Keywords produced by core members and big sub-groups in the co-authorship network were further classified into distinct conceptual groups to reveal different ideas and research foci of those major contributors.

In the end, newcomers in the research community were identified through publishing patterns, and their keyword usage was analyzed.

Preliminary findings and implications

There are 2136 keyword stems presented in a total of 949 publications. The ten most frequently mentioned keywords are Intelligent Tutoring Systems (n=167), Natural Language Processing (n=46), Machine Learning (n=39), Student Model (n=35), Education Data Mining (n=32), Learning Analytics (n=31), Metacognition (n=26), Affect (n=24), Learning (n=24), and Collaborative Learning (n=23). The number of keywords grows from 507 in 2013-2014 to 593 in 2015-2016, 825 in 2017-2018, and 804 in 2019-2020, possibly indicating novel ideas being regularly introduced to the IAIED society.

The IAIED co-authorship network demonstrated a right-skewed distribution in the number of authors by degree of centrality. More than 50% of the authors (1046 out of 1915) in our IAIED dataset possessed a degree of zero to four (i.e., they have zero to four co-authorship ties in total in the period of 2013-2020). We identified 35 core members, who had more than 20 total co-authorship ties and analyzed their collaboration and publications. A majority of them (n=29, 83%) have published work on Intelligent Tutoring System. For the rest of the core members (n=6, 22.9%), all of them study Educational Games. The analysis of core members' publications reveals Intelligent Tutoring Systems and Educational Games being two major research topics in the IAIED society. In addition, the integration of new community members is vital to the growth and vitality of a scientific community. In attempting to measure such integration, we proposed five categories of authors in terms of their publishing patterns from January 2013-October 2020. The large size of the Joined Recently group (n = 542) shows the growth of the IAIED society from the perspective of membership. Additionally, the keyword analysis shows an increase of more than two hundred keywords during this same period of time (2019-2020).

Research topics of the IAIED society can also be investigated by analyzing the most frequently used keywords in large co-authorship cliques. The largest sixteen cliques were inspected, and they consist of nearly half (49.3%) of the authors in the IAIED society from 2013 to 2020. Intelligent Tutoring Systems (n=10, 62.5%), Game-Based Learning (n=3, 18.8%), Collaborative Learning (n=4, 25%) and Conversational Agents (n=3, 18.8%) are the major topics in these cliques.

One unexpected finding from our analysis is the use of synonymous but distinct terminologies to describe the same concepts in different cliques. This phenomenon may hinder inter-group communication since multiple terminologies need to be learned and used accordingly. In further research, we would like to investigate how different cliques developed over time.

Besides an in-depth analysis of the IAIED research community, an important contribution of this work, with applicability to the larger Learning Sciences community, is methodological. AIED (and LS) are new, interdisciplinary, and still under construction. Most of the literature we found on bibliometrics was focused on well-defined communities. Many of the methodologies we developed in this paper were created for these types of novel research communities with "fuzzier," "in-flux" keywords. We also developed a novel way of categorizing author participation in a research community based on publishing patterns. In this way, newcomers in the community can be identified, and the integration of new community members can be studied. Our future research will apply the method to other closely related research communities (e.g. Educational Data Mining, Learning Analytics, and Learning at Scale) to validate current findings and explore more emerging trends.

Productive Anger? Changing Systems Understanding due to Negative Emotions

.

Taehyun Kim, University of Illinois at Urbana Champaign, thk4@illinois.edu
Vishesh Kumar, University of Wisconsin–Madison, vishesh.kumar@wisc.edu
Mike Tissenbaum, University of Illinois at Urbana Champaign, miketissenbaum@gmail.com

Abstract: There is growing interest in the role that emotion plays on learning. Research has revealed that negative emotions sometimes positively effect learning; however, most of these studies focus on individual learning situations. In this pilot study, we explore how anger during collaborative learning affects students' discussion and learning. Result indicate that negative emotions could facilitate potentially productive shifts in student discussion.

Introduction

There is growing interest in the role that emotion plays on learning (Pekrun & Stephens, 2010). While negative emotions (e.g., anxiety, fear, frustration, anger, boredom, and embarrassment) have been shown to have an impact on learning, not all of them have been negative (Rowe et al., 2014; White, 2013; Pekrun & Stephens, 2010). For instance, anger can derive from interruptions of perceived goals, creating a motivation to overcome obstacles. Anger can result in increased attention to goals, others' actions, higher levels of physiological activity (e.g., increased heart rate, breathing) and aggression. However, research on the effects of negative emotions on learning is mostly related to test anxiety and boredom, and there is a lack of research on the effects of other negative emotions on learning (Pekrun & Perry, 2014). In particular, most studies focus on individual learning situations, and research on the effects of negative emotions on collaborative learning is less known. As a pilot study, we explore how anger during collaborative learning affects students' discussion and learning.

Methods

Simulation and study design

City Settlers is a whole-room immersive simulation, in which the room "becomes" (through collective imagination) a fictional shared planet on which groups of participants develop their cities. In *City Settlers*, each group can freely set their goals with given city metrics (e.g., pollution, population, and happiness) and develop strategies to achieve their goals. Four types of resources (e.g., Gold, Steel, Food, and Cotton) and three types of buildings (e.g., Factory, Farm, and Park) are available to players. Buildings are acquired through bidding – a blind auction system on a marketplace which generates random buildings to be acquired and used by the cities for their chosen goals. While students are trying to understand complex interrelationships for their city to prosper, groups inevitably cause pollution (all the buildings except parks generate pollution). If a city's pollution level reaches a certain level, the pollution spreads to nearby cities (i.e., those physically close in the room itself). We expect this unexpected problem (rising pollution caused by neighboring cities) will cause emotional changes in students, especially anger, and allow us to track how the students' group discourse is changing.

The participants were 10 middle school students recruited from a summer camp, in the mid-western United States. Seven girls and three boys of different ethnicities were distributed randomly into four groups, introduced to the simulation, and asked to start playing. They played the simulation over 1.5 hours. As qualitative exploratory analysis is considered an effective approach for developing insights into the range and phenomenology of an individual's emotion (Pekrun et al., 2002), we video recorded all four groups' game playing with the goal of identifying anger and changing discourse. As a preliminary study and with the page limitation, we focus on one group (consisting of three girls) that consistently worked on the simulation.

Coding scheme

To determine when the group of students expressed anger, we adapted Shaver and colleagues' (1987) definition that anger happens when people judge that the situation is illegitimate, wrong, or unfair. This sometimes occurred through raised voices, yelling, or screaming. In addition, to determine changes in their discussions, we also developed a coding scheme for the types of discussion enacted (Table 1). The three authors were all involved in coding and agreement was checked across 25% of the total coded turns and were found to have an agreement rate of 88%, 85%, 82% respectively (1st - 2ed; 1st - 3rd; 2nd - 3rd).

Table 1: Discussion type codes and examples

Code	Definition	Sample dialog from
What to buy	Talking about which building they want to buy.	“I want to buy a factory”
What to run	Talking about what building they want to run for the current round.	“We should stop running this park”
What to trade	Talking about what resources they want to trade with other groups.	“We’ll give you anything for food”
Game state	Talking about their city status including the metrics, resources, and buildings.	“Our happiness is so low”
Other group	Talking about anything related to other groups.	“They are polluting us”
Causal	Talking about what causes what.	“If we don’t buy a park, our happiness will drop”

Findings

Students exhibited angry episodes when pollution suddenly increased (a by-product of building too many factories and farms) and caused their city’s happiness to decline. After noticing that pollution came from another group's city, individuals showed a hostile attitude toward that city (e.g., [Yelling] Red city! Stop it! Stop polluting us!). The results of comparing the discussion codes before and after students start to get angry reveal some interesting contrasts (Table 2). Before becoming angry, more than 50% of the discussion codes were about “What to buy” and “What to trade”. However, after a group was coded as angry, there was a notable increase in “Game state” and “Other group” codes, whereas “What to buy” and “What to trade” codes considerably decreased.

Table 2: Discussion type code count before and after angry

Code	Before angry	After angry
What to buy	32%	19%
What to run	3%	3%
What to trade	20%	11%
Game state	35%	43%
Other group	6%	16%
Causal	5%	8%

Discussion

We acknowledge that there could be other variables (e.g., time, other emotions) that we didn’t control which likely affected students’ discussion type. However, as a preliminary examination of how students' anger could affect their collaborative and strategic discussions, this work lays a foundation for future elaborative research regarding how "negative" emotions could facilitate potentially productive shifts in student discussion. The increase in the “Game state” code and “Other group” code and the decrease in the “What to buy” and “What to trade” code after students become angry, may indicate students tried to understand and analyze the complex situation and establish strategies based on the city's needs, rather than focusing on immediate short-term goals (e.g., buying a building).

Abstract: Practitioners of active learning have asked us what Learning Sciences research has found that can inform their practice. In response, we are conducting a rapid review of Learning Sciences articles referencing common active learning approaches and strategies. This study identifies inquiry-based learning, argumentation, and problem-based learning as the top active learning approaches researched within the Learning Sciences and includes early summaries based on an ongoing synthesis of findings.

Introduction

Active learning is on the rise in mainstream education, characterized by the adoption of interactive, student-centered activities and technology-enhanced learning spaces. The Learning Sciences has developed predominantly independently of the active learning research community, but the two share some common contexts, learning approaches, strategies, and goals (e.g., real-world contexts, problem-based learning, jigsaw, and technology-enhanced collaborative learning). But what has the Learning Sciences found that could inform classroom enactments of active learning activities? To answer this question, we are conducting a rapid review of Learning Sciences articles that investigate common active learning approaches and strategies. We began this process by focusing on ISLS's two affiliated journals: the Journal of the Learning Sciences (JLS); and the International Journal of Computer-Supported Collaborative Learning (ijCSCL). Our results identify the extent to which active learning approaches are common in Learning Sciences research and offer a few early findings from our ongoing synthesis of the literature.

Methods

This research utilizes a rapid review methodology and follows the stages described by Arksey and O'Malley (2005) to guide this integration of evidence. The guiding research question is: "What empirical findings of the Learning Sciences relate to active learning approaches and strategies?" Search terms of active learning approaches and strategies were sourced from SALTISE, an active learning, research-practitioner community (see saltise.ca). Terms included both active learning approaches (e.g., inquiry-based learning) as well as strategies (e.g., snowball, gallery walk, and jigsaw). In the study selection phase, abstracts were reviewed by two graduate researchers. For this paper, we identified the top 3 search terms found during our abstract screening phase: inquiry-based Learning (N=52), debates (and argumentation; N=40), and problem-based learning (N=20). A brief overview of findings from these approaches are summarized below.

Results and discussion

Search results produced 262 studies from JLS and 236 from ijCSCL. After removing one duplicate study, the remaining 497 underwent abstract screening, after which 115 studies remained eligible for full-text review.

Preliminary findings relating to inquiry instruction emphasize the shifting instructional focus from teacher-based or -led instruction to student-lead inquiry. In our reviewed studies, inquiry-based instruction was found to benefit to student learning, specifically in the flexible application of acquired knowledge to open-ended questions (e.g., Song & Looi, 2012; Lee et al, 2006; Kolloffel et al, 2011; Muukkonen & Lakkala, 2009). The literature showed no detriment to performance in other types of assessment, implying that inquiry-based instruction is effective across multiple assessment mediums. Key to the effectiveness of inquiry learning is the manner of instruction. In Puntambekar et al. (2007) it was found that a teacher's pedagogical style significantly influences the results of inquiry-based lessons. Further they found that by focusing on the goal, rather than the student's journey to that goal, teachers can undermine inquiry instruction rather than support it. Overall, inquiry-based instruction shows robust evidence for the improvement of acquired knowledge across multiple age groups, and learner categories, provided the teacher's instructional practice supports the students' learning journey.

Regarding debates (and argumentation), this review found articles highlighting use of this approach in classrooms with learners from middle school to teacher education. Instructors employed various digital tools to scaffold the debate process and to analyse the argumentation process. Brom et al. (2016) found that debates stimulated positive affect when students developed and articulated their opinions about pressing issues such as immigration policy, stem-cell research, and agricultural quotas. Further, in Schwarz et al. (2011), tools aiding synchronous argumentation activities showed increased conceptual learning as well as uncovered mechanisms for conceptual change - fostered through interactional analysis. The research further shows that argumentation, even in cases of disagreement, provides opportunities to foster collaboration and critical reasoning. In Schwarz et al. (2015) a fusion of inquiry, argumentative process, and teamwork allowed students to see new perspectives and the value of learning to collaborate. Therefore, argumentative activities such as debates promote reflection and evaluation of evidence. It should be noted, however, that the debate approach of active learning is distinct in many cases from the scientific argumentation common to the reviewed literature. This distinction will be examined and further elaborated in future publications of this data.

Problem-based Learning (PBL) was found to describe prescribed sequences of activities and practices, guided by coaches, that create opportunities for students, individually or in a group, to hypothesize solutions for given issues that they may not yet fully understand (Kolodner et al., 2003). As with argumentation activities, students working in PBL groups need to be aware of their collaborators' knowledge, and find ways to externalize their own knowledge, as an explicit way to facilitate team efforts (Engelmann & Hesse, 2010). Lastly, PBL supports professional development, such as teachers who are often isolated, to come together to address ill-structured problems in their practice, enrich conversations through anecdotal lived experiences, or generate hypotheses to expand their understanding on teaching and learning (Zhang et al., 2011).

In conclusion, this paper represents a preliminary report on empirical findings of the top three most researched active learning approaches within the learning sciences: inquiry-based learning, debates (argumentation), and problem-based learning. A future report of findings will fully synthesize eligible papers in the dimensions of interventions, definitions, theoretical frameworks, methods, disciplines, and demographic information.

Stanford University

Abstract: The Covid-19 pandemic drastically changed family dynamics and daily routines across the United States. In this poster, we present contrasting cases from a remote diary study showing how two mothers are demonstrating family resilience during the pandemic by developing open or closed communication practices to support their children's psychological well-being during Covid-19. The findings of this study contribute to the development of a spectrum of family resilience communication practices to make sense of uncertain times.

Keywords: communication, family resilience, child well-being, Covid-19, case study

Literature review

Recent reviews of research that document how families cope with natural and human-made disasters predict dramatic variation in adaptations to pandemic-driven social, economic and health related stressors (Holmes et al., 2020). Resilience in the face of these traumas is a dynamic process, with responses ranging along a broad continuum. Research on family resilience in particular shows that adaptation is supported when caregivers and children develop shared belief systems that foster positive outlooks, help make sense of adversity, create a sense of togetherness, and nurture value-driven transcendent perspectives within culturally meaningful frameworks (Walsh, 1996). Family resilience has been studied as an outcome and as interactional practices and routines which involve "organizational patterns, communication and problem-solving processes, community resources, and affirming belief systems" (Walsh, 1996, p.1). In this study, we focus on understanding communication processes caregivers employ related to child well-being, since the well-being of young children is of central concern during the pandemic (Golberstein, Wen & Miller, 2020). We examine the following research question: How do caregivers vary in their communication behaviors to support their child's well-being? In this particular health crisis, the virus is a major source of anxiety for parents and children and it is critical to understand how families are communicating about it.

Methods

Participants were selected from the dscout panel, equally distributed by household income brackets (<\$50K, \$50-99K, and over \$100K). They lived in 28 states, and 55% identified as White, 16% Black, 15% Hispanic/Latinx, 9% Asian, and 4% Middle Eastern/North African. Each selected one child in grades K-5 to focus on in the study (53% were K-2). We selected two mothers, Alice and Tyra, from the larger diary study using the dscout app (Pozos et al., 2021). We took a case study approach (Yin, 2017) and selected two cases which were both similar in parent role (i.e., mothers), child age (i.e., 5-years old), and child gender (i.e., female); however, these mothers represented opposite ends of a spectrum from open to closed communication based on Walsh's family resilience framework. Alice is a 36-year-old white woman who is a homemaker in a high-income household making over \$99K annually. Tyra is a 36-year old African-American woman working as a full-time clinical coordinator in the healthcare industry, making between \$50-99K annually.

Findings

As summarized in Figure 1, Alice expressed a need to protect her daughter's well-being, which she planned to implement by shielding her daughter from harmful information, down-regulating negative emotions, and redirecting attention from Covid-19. In contrast, Tyra demonstrated communication processes for family resilience that were characterized with clarity, open emotional sharing, and collaborative problem solving to validate her daughters' feelings and learn together about Covid-19.

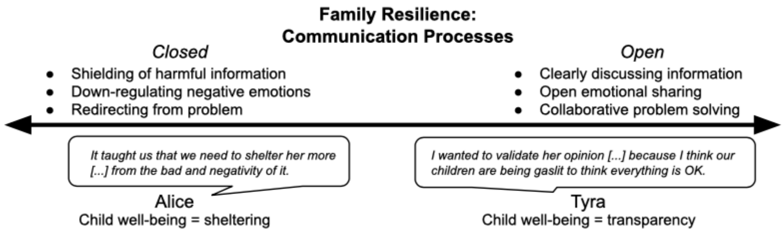

Figure 1: Spectrum of family resilience communication processes from closed to open

Alice decided to protect her daughter Sammy's well-being by not mentioning Covid-19 and not turning on the news to protect her from being frightened by the pandemic. Sammy asked Alice, "What is coronavirus?", "Are people dying?", and "Can kids get it?" Alice's response is described in the quote below:

> We didn't want her to hear all that. You know, the details. I wanted her to know that Coronavirus is out there and people are getting sick and everything like that. But I think a little too much information for her little ears. So it was sad. It was sad that my child had to worry something about the Coronavirus and people dying and everything like that. But it taught us that we need to shelter her more and not talk about Coronavirus around her, and shelter her just from the bad and the negativity of it.

Tyra, on the other hand, is willing to listen to her daughter Tiana's inquiries and answer them as authentically as she can. In this way, she is protecting her daughter's well-being by making sure Tiana feels validated and heard. For example, Tiana asked her mother why China had reopened. Tyra's response is captured in the response below:

> She is coming up with her own novel ideas about how things should work. And I wanted to validate her opinion in that moment because I think even our children are being gaslit in one way or another to think that everything is OK... She's much too young to think that what she has to say and her opinion is crazy because it's not. And just to continue to keep the lines of communication open and I just tell her, you know, if you have other questions just ask me, you know, and I'll try to answer them the best I can.

Overall, Alice and Tyra's contrasting cases demonstrate how sociocultural context and caregivers' experiences may influence their communication practices around child well-being practices. Future research includes examining a broader range of contexts and experiences in the larger sample. During a time when much of the literature has focused on the negative consequences of Covid-19, this work has significant implications by contributing a strengths-based family resilience framework of communication practices.

Expanding the Learning Sciences Toolkit and Reach: A Methodology for the Critical Analysis of Discourse Across Media

Maximilian K. Sherard, Flávio S. Azevedo
msherard@utexas.edu, flavio@austin.utexas.edu
Department of Curriculum and Instruction, The University of Texas at Austin

Abstract: We blend Entman's and van Leeuwen's work to advance a novel methodology for the critical analysis of discourse in text media.

Introduction

We add to LS scholarship by pursuing two parallel goals that tackle issues little studied in our field. First, we advance a methodological approach that blends Entman's (2007) framing analysis and aspects of van Leeuwen's (1996) critical discourse analysis (CDA) to distill the relationship between written texts and larger political discourses circulating in society. In demonstrating our methodology, our second, parallel goal is to expand the analytical foci of learning sciences research to consider the discourses of STEM equity that circulate in popular science magazines—*Scientific American*, in this case.

A novel approach to the critical analysis of discourse

We aim to synthesize a simple, yet powerful enough blend of critical CDA tools to facilitate the application and use of these techniques/frameworks to problems directly concerning learning scientists. First, we use Entman's (2007) framing analysis to understand the *content* of a particular text (i.e., what is being said by the author). A frame is the central argument of a text and consist of four elements: *problems*, *causes*, *moral judgments*, and *remedies*. Not all sentences conduct one of the four framing elements, and some sentences may conduct more than one. Researchers proceed by reading all sentences in a text and coding sentences which conduct one of the four framing elements. Once coding is completed, researchers extract those sentences that summarize the frame(s) in a particular text, thus composing a synthetic picture of how the text articulates a problem, its causes, remedies, and moral judgments. At this point, analysis may be deepened by comparing and contrasting frames present within a single text (if at all) or, more importantly, across texts produced by different authors. Extracted sentences are then explored using tools from CDA.

CDA analyzes text at the clause level to identify patterns in language use that reflect societal discourses. Discourses are relatively stable ways of representing the world through language (Fairclough, 2003). To do this, we analyze how *social actors* are represented in texts. Social actors can be any person, group, or even inanimate objects, all of which are capable of doing things or having things done to them. Analyzing social actors entails examining: (a) the *inclusion* or *exclusion* of social actors; and (b) the *activation* or *passivation* of social actors. Included social actors are named in the text, whereas excluded actors are not. Excluded actors are identified by comparing different texts written about similar topics. When social actors are included, they are activated by conducting the action of the verb or passivated by receiving the action of the verb. Researchers proceed by decomposing sentences identified in the framing analysis into clauses, **bolding** social actors (often represented as nouns or pronouns) and <u>underlining</u> verbs. For example, the clause '**Laura** <u>saw</u> **Fiona** in Bochum' has two social actors (Laura and Fiona) and one verb (saw). We code social actors who are included and compare across texts to determine which social actors may be excluded. We examine the relationship between social actors and verbs to code included social actors as either activated or passivated. Patterns in which social actors are included or excluded, and how included social actors are activated or passivated indicate larger social discourses. By iteratively coding social actors within texts and making comparisons between text, we can identify competing social discourses.

Discourses of equity in popular science magazines: Two examples

We demonstrate our methodology with the analysis of two articles (taken from *Scientific American*) that tackle the issue of equity is STEM fields. The first article is titled *Engineering is a man's field: Changing a stereotype with a lesson from India* and it compares enrollment of women in post-bachelor engineering programs in India and the United States of America (Aggarwal, 2013). The second article is titled *Science must clean up its act* and it discusses exclusionary practices in STEM fields, situating that discussion within the author's personal life and an analysis of the 2017 March for Science—a political demonstration where scientists gathered in Washington, D.C. to protest anti-science sentiments growing in the public and government (Metcalf, 2017).

	FA - Problem Definition	CDA - Problem Definition
Metcalf (2017)	"The scientific community, riddled with a history steeped in scientific racism, sexism, and toxic colonialism, has continuously struggled with diversity, equity, and inclusion issues, including systemic bias, harassment, discrimination, and more, all while claiming objectivity." (Paragraph 3)	**(Scientific Community)** (is) riddled with a history (**history**) (is) steeped in scientific racism, sexism, and toxic colonialism **Scientific community** has continuously struggled with diversity, equity, and inclusion issues including systemic bias, harassment, discrimination, and more. **(Scientific Community)** claiming objectivity
Aggarwal (2013)	"We were surprised to find that India has a much lower (better) male-to-female ratio (as compared with the U.S., that is, engineering male-female ratio in India is 1.96 as compared with 4.61 in the U.S. (American Society of Engineering Education, 2009). Interestingly, India does much better than the West on this dimension of gender equity despite being ranked 19th in gender equity among the G20 countries (Thomson Reuters Foundation, 2012)." (Paragraph 2)	**India** has much lower (better) male-to-female ratio, **Engineering Male-female ratio** is 1.96 in India **(engineering male-female ratio)** is 4.61 in the US **India** does much better than **the West** on this dimension of gender equity **(India)** being ranked 19th in gender equity among G20 Countries

Figure 1. The problem definition sentences extracted from FA and prepared for CDA analysis.

We begin by individually reading both articles multiple times, then coding sentences in each according to framing analysis categories of *problem definition* [PD], *causal analysis* [CA], *remedy promotion* [RP], or *moral judgement* [MJ]. This non-linear process involves iterative and collaborative attempts at reading and coding. In the final pass, researchers place a bolded and bracketed code at the end of each sentence, then collaborate to discuss disagreements and to work on a final coding for both texts. Following the coding process, we create a schematic which summarizes each article's frame and contains (one or more) quotes that are synthetic of each frame. We then proceed to the last step in the framing analysis—namely, intertextual frame comparisons aimed at identifying differences between framings of similar social events. To facilitate this process, we place each frame's element side-by-side, as shown in Figure 1. For brevity, here we only show the frames' *problems* identified in each article (Figure 1), leaving treatment of *remedies*, *causes*, and *moral judgements* to an upcoming manuscript.

With framing analysis complete, we have a surface level comparison of the content differences between each of these articles related to how they understand issues of equity in their fields, specifically which issues they consider to be problems. However, we do not yet have a defensible way to identify the discourses that each text relies upon to make their frames and arguments possible—a step that would allow us to pinpoint which discourses circulate the professional STEM world. To do this, we apply CDA to sentences extracted from the framing analysis.

To prepare sentences extracted from the framing analysis for CDA, we break them into clauses, focus analysis on main clauses, **bold participants,** and underline processes. To determine which social actors are *included* and *activated* or *passivated*, we identify the verb, then identify which social actor is conducting or receiving the verb. To determine which social actors are *excluded* we make comparisons between multiple texts, as well as ask questions about what may have been present in the social event that was not captured in the text. Once all social actors have been identified and coded, we draw comparisons between texts to identify divergent or convergent patterns that emerge within or between texts that indicate larger social discourses about equity.

After preparing the sentences extracted from the Aggarwal article, we can identify three participants: India, engineering male-female ratio, and the U. S./West**.** India and the West/U. S. are both mentioned in the text. While 'engineering male-female ratio' is not a person in the typical sense, it is considered a participant/social actor because it conducts the verb "is." Participants represented in parentheses (such as "India") are done so because they are implied by the verb. After preparing the sentence extracted from Metcalf's article, we can see there is only one social actor that is mentioned across the three clauses: **the scientific community**. This comparative exercise thus begins to reveal two competing discourses of equity in STEM. Aggarwal draws on a discourse which represents issues of equity as existing in some places (the U. S.) but not in others (India); whereas Metcalf draws on a discourse which represents issues of equity as existing everywhere in the STEM community and makes no mention of where these issues might be greater or lesser.

Here, we demonstrate this methodology on a single framing element across two texts. The power in this method increases as you analyze all framing elements and make comparisons between multiple texts.

Abstract: Most electronic devices have complex circuitry systems embedded in flat and thin structures called printed-circuit boards (PCBs) traditionally to learn at the university level. We systematically compared how 21 youth (ages 15-16) learned basic circuitry concepts and PCB layout design principles using two educational circuitry toolkits, paper circuits or the traditional solderless breadboard for prototyping. Statistical tests of pre- and post-assessments showed large effect sizes (*Hedges' g*) of the score-gain differences favoring paper circuits.

Introduction

Electronic devices, ubiquitous in our fast-paced and interconnected world, are built with complex circuitry systems usually hidden from the users' view and embedded in flat, thin structures called printed-circuit boards (PCBs). PCBs resemble a matrix of layered highways that allow energy to flow in and out of multiple microelectronic components. The different ways learners interact with educational electronic toys and kits, actually do present opportunities to substantially shape learning and participation (Buchholz et al., 2014). However, little research exists on the toolkits' efficacy and how their design features, like the role of materiality, best support learning. In this exploratory study, we sought to explore how each of these toolkits impacted the learning of simple circuitry concepts and advanced PCB design principles by asking: *How do each of these toolkits impact the learning of simple circuitry and advanced PCB design principles? What are the design features of the kits that seem to best support learning?*

Theoretical foundations on learning and materiality in circuitry

This work builds on constructionist theories of learning (Papert, 1980) which perspective asserts that learners construct understandings based on hands-on experiences with tools and materials, particularly through activities that involve the iterative design of personally meaningful artifacts (Peppler & Glosson, 2013). Prior research has demonstrated that the teaching of electric circuitry frequently produces common conceptual misunderstandings, particularly in the areas of *current flow*, *connections*, and *polarity* (e.g., Shepardson & Moje, 1994). Moreover, materials and tools to teach early circuitry can also contribute to erroneous conceptual conceptions (e.g., nonpolar lights, insulated wires) that persist into university level courses (Fredette & Lochhead, 1980).

Methods

For this quantitative study, we held two circuitry workshops in a science museum introducing solderless breadboards and paper circuits (Chibitronics™). The solderless breadboard has been one of the most common toolkits for over 60 years for electrical circuit learning in electrical and computing engineering labs (Figure 1-3). Paper circuits (Figure 1-2) are a recent toolkit that combines paper crafts and arts with circuitry (coin batteries, paper, copper tape, and sticker lights). The workshop participants were 21 youth, ages 15-16 years old, 12 participants for the breadboard group and 9 participants for the paper circuits group. Informed by our prior work (Peppler & Glosson, 2013), we administered one pre- and post-test on basic circuitry concepts (*polarity, current flow, connections*). We performed t-tests using gain scores (post- minus pre-mean scores).

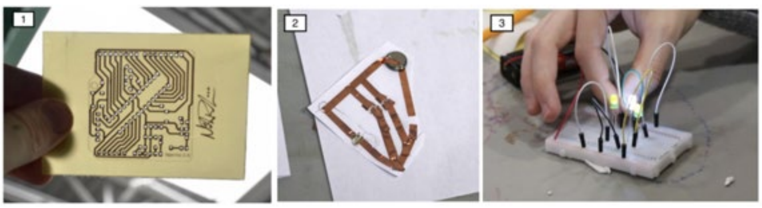

Figure 1. Similar parallel and non-crossing traces in PCB (1) and paper circuit (2) but not in breadboards (3).

For effect sizes, we calculated Cohen's *d* (Cohen, 1988) and its correction for small sample sizes, Hedges' *g* (Hedges & Olkin, 1985). We also analyzed and scored their tests for evidence of appropriate use of the four PCB (see Figure 1-1) layout design principles. Expert PCB designers consider three areas: (1) space allocation or floorplanning, (2) placement of components, and (3) routing or trace positioning (e.g., Wilson, 2018). We narrowed to *polarized component orientation, trace-to-trace spacing, power and ground distribution.*

Findings

We show the results of the comparison of mean gain scores *between* groups (i.e., independent-samples t-tests) in Figure 2. The only statistically significant difference at the .05 level was the mean gain score in the paper circuits for *polarity*, higher than of the breadboard group t(17.817) = -2.458, p = **.024**, and a large effect size Hedges' **g = 1.03**. The mean gain scores were higher in all four principles in the paper circuit group, but only three statistically significant at p < .10 level (see Figure 2-*right*). The results of the independent-samples t-tests indicated the highest mean gain scores were for the paper circuit group for *power distribution*, *trace spacing* and *orientation of polarized components.* We also calculated effect sizes (Hedges' g) for the paper circuit group.

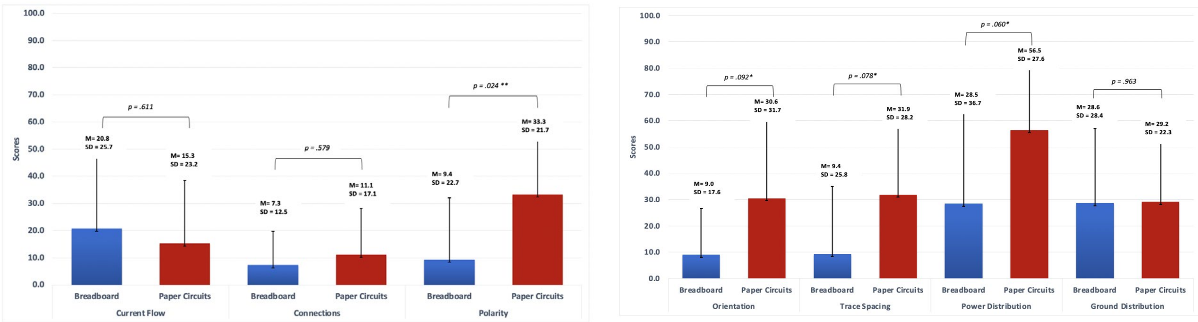

Figure 2. Comparisons of Mean Gain Scores of Basic Concepts (*Left*) and of Layout Design Principles (*Right*). Mean (M), Standard Deviation (SD) and statistical significance (p) at the *p < .10, **p < .05 levels.

Those effects sizes were large for the basic concept of **polarity** (g = **1.03**) and for the layout design principles of **orientation of polarized components** (**.84**), **trace-to-trace spacing** (**.81**), and **power distribution** (**.81**).

Discussion and implications

We encourage educators to carefully select educational toolkits considering the properties of their materials. Breadboards may be a traditional go-to toolkit, but in our study, paper circuits seemed to afford better understanding of some basic concepts, such as polarity, and PCB layout design principles. The familiar nature of the paper circuits materials and their placement in a 2D space offers similarities with the actual space and nature of a 'real' PCB (Fig. 1). Breadboards may cut out problems for novices, such as the use of insulated wires and a grid to temporarily and quickly place components, but also seem to prevent deeper learning opportunities.

Emergent Learning Possibilities and Evolving Design Spaces in Students' Redesigning the Pandemic Board Game

Reyhaneh Bastani, University of Calgary, reyhaneh.bastani@ucalgary.ca
Beaumie Kim, University of Calgary, beaumie.kim@ucalgary.ca

Abstract: We discuss a study on grade 7 students' exploring emergent systems while redesigning the board game Pandemic using mathematics and science topics. We evaluated students' developing ideas and the unfolding learning possibilities through the redesign process. Our findings show how game redesign supported learners' decision making and their evolving conceptions of problems.

This project used a board game redesign approach to learners' engagement with emergent systems using mathematics and science. We follow the concept of learning as an emergent phenomenon that expands learners' capacities to adapt to and participate in novel situations. Complexity perspectives use the notion of enabling constraints: appropriate structures in learning designs free learners from having too many choices, provide shared goals and language, and enable learners' different responses (Davis & Sumara, 2006). We discuss how the board game redesign approach sets structures that enable students' collective decisions, which eventually expand their engagement with math and science topics. We attended to the following questions: How did the learners' co-design spaces evolve through the redesign process? How did learners' decisions frame their designs and use of math and science in creating game systems?

The literature on design similarly signifies constraints as shaping creative pathways (Sternberg & Kaufman, 2010). Constraints could be external such as materials, or self-imposed emerging from designers' ideas and decisions. With every decision, designers impose constraints on their work that not only restrain the next actions, but also become tools to think with and to explore new design spaces. Design space is interpreted as a dynamic conceptual space of possibilities that is constructed as designers go through the design process (Biskjaer et al., 2014). Systemic perspectives describe it as continuously developing through the interactions of designers and design conditions. Designing board games, as models of systems, could engage students in developing and shaping the design space with mathematics and science (Kim & Bastani, 2017; Saxe, 1992). Kim et al. (2020) showed structuring game design projects as re-designing board games, in which learners play a common board game and change its elements to create their own games, enabled learners to creatively engage with disciplinary ideas. The common starting point and physical material supported learners' communication and shared goals. In the iterative process of design, learners' evolving decisions become frames that direct their further inquiry into design problems. Using our data, we will discuss how learners' design decisions developed through redesigning the Pandemic board game and enabled them to expand their ideas and use math and science topics, thus their design space.

Research design and data sources

We conducted this design-based research with grade 7 students in a Canadian school, in Fall 2018. We developed the activities with the math teacher (also a game designer) and focused on the topics of numbers, statistics and probability, and the science topics of interactions and ecosystems. We collected ethnographic data through field notes, video-recordings of students' designs and group interviews. We used the cooperative game Pandemic which models disease spread across the world (Figure1a), as the game to be redesigned. We used it as a model of an emergent global issue. In this game, players work together to treat infected populations and discover the cures. The student groups began by playing the game. Then they brainstormed on design ideas and using learning topics and redesigned Pandemic.

Findings

Our unit of analysis was the critical episodes in which the interaction of learners' ideas, materials and activities transformed their collective design space. Here, we chose one group whose redesigned game was Reverse Pandemic. The group's design decisions enabled them to expand their ideas and use of math and science, thus their design space.

The group developed the idea of reversing Pandemic's narrative, i.e., players would act as diseases spreading around the world, which directed their design process. We observed that the Pandemic's physical materials, e.g., the cubes representing viruses and board map, mediated their discussions on game redesign ideas.

Initially, they tried to implement their idea of reverse Pandemic by defining opposite functions for the original game's components (e.g., cubes representing cures instead of diseases). While this approach might not be helpful in reversing the dynamics of a game system it encouraged them to explore the original game system.

It was important for the group to taking the perspective of bacteria and viruses. In a critical episode, their conversation around Pandemic's and their own game's theme with a science teacher led to elaborating their game backstory through exploring how bacteria and viruses act. They discussed how bacteria develop resistance against antibiotics and mutate and how viral diseases spread with international travels. Discussing cities' defence against diseases, they talked about how vaccines could develop widespread immunity. An intentional interaction between students and teachers mediated by Pandemic's board and other components supported integrating learning topics. The group's work showed that mathematics can become a tool to materialize ideas. The group found to reverse the Pandemic's narrative, they needed to understand the game's system more deeply. They evaluated the infection cards that determine the cities to be infected based on designed probabilities, and the epidemic cards that trigger an outbreak. Their choice of reversing the Pandemic's story became about reversing its logic: i.e., their design problem evolved so as their choices and design space, exploring more possibilities of using math. They created numeric values for players' power (diseases) and adopted probability for vaccination cards (one out ten players' cards were vaccination cards), which made cities' defence dynamic. The group's goal of having playable drafts and playtesting (Figure1b) encouraged them to use mathematics in different design stages from the beginning. Students could experience the problems in context by confronting their own designs (Kim et al., 2019) and could develop more holistic views about this complex system.

(a)  (b)

Figure 1. (a) Pandemic, Z-MAN Games, (b) the group's redesigned game

Conclusions

We structured this project as a board game redesign to limit the vast possibilities of creating a game from scratch, and support learners' shared conception of their design practices (Bastani & Kim, 2020). Students used the original game's languages and components and shared the goal of reversing its theme. Game redesign enabled collective decision making, through which learners explored novel paths of integrating learning topics: i.e., expanded their design space.

Supporting Collaborative Learning About the Nature of Science and STEM Identity Development in a High-School Biology Class in Ontario

Elena Boldyreva, University of Toronto, elena.boldyreva@mail.utoronto.ca
Maria Niño-Soto, University of Toronto Schools, maria.nino@utschools.ca
James D. Slotta, University of Toronto, jim.slotta@utoronto.ca

Abstract: Our study conducted in a Grade 11 Biology classroom focused on supporting students' development of the 21st Century Competencies, NOS understandings, and students' STEM identity. A scientific learning community approach, supported by technology, was implemented to improve inquiry-based learning and students' collaboration and thinking processes. Students co-constructed a common knowledge base to make connections across topics. Our findings showed a potential of a learning community approach in helping students develop the competencies of critical thinking about resources, collaboration, and scientific argumentation, and explore their STEM identities.

Keywords: learning community, collaborative learning, STEM identity, Nature of Science

Introduction

Our research study was conducted with a Grade 11 Biology classroom in a diverse urban school located in Ontario, Canada. Students were engaged as a scientific learning community by exploring case studies and datasets, evaluating the credibility of online and published resources, developing scientific argumentation and participating in debates, reflecting in personal journals and working together to explore the Nature of Science (NOS) and STEM-related careers. Guided by a theoretical model of Knowledge Community and Inquiry (KCI - e.g., Fong & Slotta, 2018), we co-designed a curriculum in which students made connections across course units and connected to real-life issues. A substantial research literature has addressed the benefits of a learning community approach (Bielacyzc & Collins, 2006; Slotta & Najafi, 2013), such as developing and advancing a shared community knowledge base (Bereiter & Scardamalia, 2014; Fong & Slotta, 2018). By engaging in a scientific learning community, students develop collaborative skills and become independent problem solvers (Smithenry, Gallagher-Bolos, & Kosnik, 2007).

Our primary research question: How can engagement in a scientific learning community support the development of high school students' scientific competencies, collaboration, NOS understandings, and STEM identities?

Theoretical framework

We applied the KCI model to guide the design of a curriculum in which students work together as a community, developing scientific argumentation and critical thinking (e.g., through discussions and evaluation of source credibility), improving their understanding of the NOS and exploring STEM careers. In the KCI model, students create a common knowledge base which is further used in the activities; they can add new ideas to the base, can edit and improve it (Fong & Slotta, 2018). Students participate in the interactions and scientific argumentation reflecting some practices characteristic of the real scientific community; they make connections within and across instructional units and connect to real-life issues. Along with a deeper understanding of scientific practices and processes, students also build their understanding of the Nature of Science, and how scientific knowledge is generated and validated.

Method

The study was conducted in a diverse urban school located in a large city in Ontario, Canada. A series of lessons co-designed with the classroom teacher used a variety of technology environments and materials (e.g., Google Docs, Google Forms, Google Classroom and Padlet) to support the curriculum and assessments. We developed a KCI curriculum for 11th grade Biology that aimed to address the research question, adding a cross-cutting diet and nutrition theme. Three cohorts of students (60 students in total) participated in the study, examining interesting evidence cases, participating in inquiry activities and engaging around ideas, connections, data analysis and critical thinking about resources. Their culminating activity included a group analysis of a case study "Atkins vs Mediterranean Diet", developed by the Tufts University and adapted by the teacher and researchers. The KCI research method included having students construct a community knowledge base, scaffolded inquiry activities, and accessible learning outcomes. Exploration of the NOS and student epistemology was effectuated through students' scientific argumentation, exploration of their beliefs about the NOS, and critical interpretation of evidence, which includes data reasoning, student-contributed evidence, discussions and debates. Students worked as a class community to address distinction between observation and inference, between scientific laws, theories, hypotheses, principles and facts. A C.R.A.A.P. rubric was used to evaluate primary and secondary resources. The teacher and researchers observed students' participation and collected evidence of their engagement – individually, in groups and as a class. A pre- and posttests of students' epistemological ideas on the NOS, Learning Communities and Career Exploration were developed. The analysis of students' responses included identification of the central ideas and scoring of the complexity of responses. Three levels of students' responses were determined: 'Partial', 'Full', and 'Complex'.

Data sources
The data collected during this study include student replies on pre- and post-questionnaires, tables, documents and journals created by students individually (on Google Forms and Google Docs), in groups and as a class (on Google Docs, Padlet, and Google Classroom), as well as classroom observation notes, audio and video recordings. Co-constructed tables and student contributions represent a community knowledge base built during school year and used by all students for their final case study activity. In scientific argumentation activities, information was collected as claims, evidence, and reasoning statements. Students' replies to the pre-post questionnaire were recorded on Google Forms. In each unit students also worked individually and in groups to build a STEM Identity and Careers common knowledge base which represented students' contributions to a career exploration folder on Google Docs.

Findings
First, our study supported students' understanding of the role of a learning community in science learning and science research, and in communication of results. In students' replies to a post-test questionnaire, students provided high-level responses on the role of a community: among scientists (e.g., contributing to a total knowledge pool, improving the credibility and accuracy of the previous ideas) and in a classroom (e.g., sharing information to peers and learning from them, learning through explanations). Second, our design supported students' communication, collaboration, and critical thinking about primary and secondary resources – through discussing, evaluating and ranking resources. KCI activities enabled student engagement and connected to important learning goals in biology. Third, students' understandings of the NOS were built progressively through all units. Students learned that scientific knowledge is subject to change as new evidence becomes available or old evidence becomes reinterpreted with the advances of technology and new discoveries in science. Finally, through exploring different careers and contributing to the class career folder, students built their understanding of STEM careers. The study demonstrates opportunities of collaborative learning and learning community approach, achieved through student work and discussions in groups and as a whole class, for helping students develop the competencies of critical thinking about resources, collaboration, and scientific argumentation, and explore their STEM identities.
We acknowledge the support of a grant from the Canadian Social Sciences and Humanities Research Council.

Embodied Geometry in Haircutting Practice

Ryan M. Gertenbach, Flávio S. Azevedo
rgertenbach@utexas.edu, flavio@austin.utexas.edu
Department of Curriculum and Instruction, The University of Texas at Austin

Abstract: We investigate the emergent, interactionally achieved, embodied geometry that two hairstylists collectively enacted during a haircutting session.

Introduction

We investigate the emergent, interactionally achieved, embodied geometry that two hairstylists enacted during a haircutting session. By stepping out of classroom environments and into the world of a professional trade, we shed light on alternative, powerful forms of embodied mathematical practices (Hall & Nemirovsky, 2012), and join efforts that seek to counter epistemological injustices and marginalization (Medin & Bang, 2014).

Theoretical framework

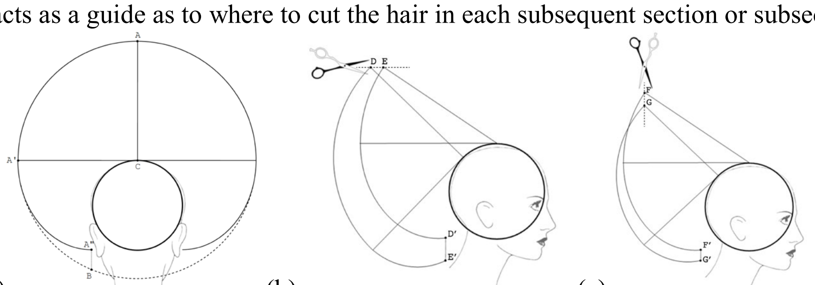
We adopt an *interactionist* perspective (Jordan & Henderson, 1995) and take it that cognition is embodied to the extent that knowing and learning are processes that take place through bodily perception and action, and which unfold within specific material, physical, and social settings (Hall & Nemirovsky, 2012). In this approach, therefore, the body is seen as "a dynamically unfolding, interactively organized locus for the production and display of relevant meaning and action" (Goodwin, 2000) and "concepts… [are] forms of modal engagement in which bodies incorporate and express culture" (Hall & Nemirovsky, 2012, p. 211). We emphasize the coordination of action between participants in a setting, the multifaceted roles that bodies take on during the process, the tool mediated character of the job, and how reasoning and action emerges from the exchanges between participants.

Empirical methods and context

We investigate a single episode of an interaction between two professional hairstylists, Steven and Brooke (pseudonyms), and a client. Steven, a male in his early forties, had specialized in cutting hair for 16 years, while Brooke, a female in her late twenties, had specialized in coloring hair for seven years. Steven and Brooke had arranged to help each other develop their coloring and cutting techniques, respectively. We focus on the session in which Steven guided Brooke through a haircutting job for which the client had requested a layered cut. We video recorded the naturally unfolding exchanges between Steven and Brooke, as they worked at a salon.

Analysis

Layers are created by cutting sections of hair so the ends of the hair fall around the head in such a manner that their overall relative lengths appear to be "graduated." In canonical geometry terms, the process rests on the concepts articulated in Figure 1. Key concepts of haircutting operate "on top" of, and in tandem with this geometry basis: (1) *sectioning* is the act of dividing the hair at the scalp to separate the hair into uniform working areas; and (2) a *guideline* (or guide) is a section of hair that establishes the length to which the hair, locally or overall, will be cut—that is, it acts as a guide as to where to cut the hair in each subsequent section or subsection.



(a) (b) (c)

Figure 1. (a) Hair extended from point C to A is free to rotate about point C until it reaches A', at which point the hair is extended in a line tangent to the head and begins to wrap around the curve of the head, effectively "shortening" in length relative to where it would fall if allowed to rotate freely. Thus, upon reaching point A', the hair wraps around the head until it falls to point A'', as opposed to point B; (b) and (c) Notice that even if the length DE is equivalent to length FG, the differences in length D'E' and F'G' differ as the hair wraps around the head, following the *involute* of the roughly circular head shape.

On this background, we pick up the action as Brooke had established the guideline (17:42) and moved to section the hair to be cut into layers. Creating precise layering effects is founded on the formal geometrical concept of *involute of a circle*. If cutting a single strand (Figure 1b), one can see that the hair rotates freely, in a *semicircular* path, until it reaches point A', at which it appears to "shorten" in length as it wraps around the head. When cutting a whole section of hair, then, the angle at which hair are elevated and cut have a drastic effect on the graduation of the layers. For instance, cutting across a section of hair parallel (Figure 1b) and perpendicular (Figure 1c) to the ground creates differences in *lengths* among the strands in the section (compare length D'E' to F'G') and, once an *angle* (parallel or perpendicular) is adopted, one must adhere to it throughout; Stephen and Brooke had decided for a parallel angle. But as Brooke was about to carry out the first cut in the process, an imprecision in cutting angle threatened to violate these principles and to introduce layering inaccuracies:

Turn	Time	Participants' talk and action annotations	Image annotations
1	18:11	Steven: ((Talk unintelligible)) ((Began moving his left hand towards Brooke))	2	18:12	Steven: Just, watch the arm bend up there ((pointing to her left wrist)).	
3	18:13	Steven: ((Talk inaudible)) ((Grabs Brooke's left arm near the wrist and lifts it so it is parallel to the floor)). Brooke (18:14): The hair? Steven: Yeah.	
As Brooke lifted the hair away from the client's head and neared her first cut stroke (turn 1), she rested her hand on the hair and held her elbow at a depressed (incorrect) angle toward the floor (turn 1, image)—in effect "bending" that hair section, rather than creating a straight line. This action, akin to disregarding a fundamental axiom of geometry, breaks the geometric basis upon which the relevant cutting theory is dependent. Immediately noticing the problem (turns 2-3), Steven directly intervened by grabbing Brooke's left arm and correcting its position and, by implication, her hand's angling and holding of that hair section.

Discussion and conclusion

We found that the geometry of hairstyling is an interactional, embodied accomplishment in that: (1) Body parts were literally operated upon, cut and discarded, according to underlying geometric principles; (2) Bodies were constantly coordinated to obtain meaningful relationships of geometrical nature; and (3) Hairstylists' actions and body posture were founded on, and expressed geometrical concepts. In all, the embodied mathematical practices we reported upon reflect a complex geometry, yet achieved through means quite different from canonical mathematical practice and based on quite distinct epistemological and ontological bases. The complexity of such math and its instantiation in a traditional trade reaffirms the power of alternative STEM epistemologies (Medin & Bang, 2014) and the promise that research on learning out-of-school holds for advancing our field.

A Review of Complexity Perspectives in the Learning Sciences

Reyhaneh Bastani, University of Calgary, reyhaneh.bastani@ucalgary.ca
Beaumie Kim, University of Calgary, beaumie.kim@ucalgary.ca

Abstract: This paper presents a summary of our critical review of complexity perspectives in the learning sciences. We provide a map which helps identify roots of complexity research. Our review identified two strands of research on complexity in the learning sciences namely *complexity as a subject matter* and *complexity as a frame* to study knowledge and learning. We address the main debates within each strand and discuss a possible dialogue between the two.

Complexity discourses have contributed to different domains of research in the learning sciences. Scholars have used complexity views to design school and classroom structures that better fit with their increasingly diverse participants (Doll, 2015). In this poster, we review the scholarly work in the learning sciences that have adopted complexity views. Two main strands of research stand out based on this review: *complexity as a subject matter,* aiming to support learners' understanding of complex phenomena; and *complexity as a frame* to study knowledge and learning conceptualized as emergent phenomena.

Our review shows there has not been much dialogue between the two strands. We conjecture that this gap is the result of disjunctions between fundamental views towards the dynamics of cognition and learning, and towards disciplinary knowledge, even though complexity is the very framework that can cross the bridge between these two threads. To elaborate on this possibility, we trace the roots of complexity discourses in different domains of inquiry and will explore how the two identified strands in the learning sciences build on complexity views.

Complexity research

Complexity research explores how diverse rule-following entities interact and shape a collective whole (i.e., a complex system). These entities, or *agents*, learn, adapt and evolve, and form a system, which shows emergent behaviors and collective patterns, without benefiting from a central controller (Mitchell, 2009). Complex systems have a number of key qualities, such as involving multiple agents, self-organization, and emergent behaviors. For this review, we first conducted a historical review of complexity research in different fields. We mapped contributions of different fields, as well as the development of various concepts which can be accessed on a digital map created by the authors (Bastani & Kim, 2020).

The first row on this map shows the emergence of complexity research, its origins and evolution in mathematics and physical sciences, as well as in life sciences and social sciences. Complexity research in mathematical and physical sciences emerged as a challenge to the deterministic views of modern science and ideal reductionism. As opposed to ideas of prefect predictability (Laplace, 1814), Heisenberg's uncertainty principle in quantum theory and Poincaré's (1908) dynamical systems emphasized the impossibility of complete prediction. Their work discredited the assumptions of the simplicity of nature. Later research on computation contributed to understanding complex systems through processing of information. Cybernetics was significant in using the notion of feedback to explain the adaptation process in complex systems (Alhadeff-Jones, 2008).

In parallel, biological sciences were influenced by evolutionary biology. Informed by the automata theory, McCulloch and Pitts (1943) developed computational models of neural systems to explain the biological processes in the brain as neural networks. These models were later applied to artificial intelligence. Connections between the evolution of living systems and the emergence of cognition were also studied (Bateson,1972).

Early research on complex social systems included Herbert Simon's work on decision making processes in organizations and human problem solving. This along with the work of others such as Bateson led to a constructivist view of complexity. Simon (1962) described complex systems (e.g., societies), as composed of interrelated entities (e.g., families), which themselves are complex and consisted of various complex parts.

Complexity perspectives in the learning sciences

In this review, we aimed to include seminal work and the main trends of using complexity discourses in the learning sciences. Our initial reading of the literature showed key trends shaping from mid-20th century. Importantly, we attended to how this scholarly work were informed by the main historical developments in complexity research and what their areas of focus were.

Our review of complexity research in the learning sciences identified two main strands. The first strand focused on design approaches to support students' understanding of complex systems. Computational modeling and simulation tools are widely used (Bastani, 2016). For example, modelling activities for students through

StarLogo (Resnick, 1991) and NetLogo (Wilensky, 1999), i.e., agent-based modeling platforms, are used to model complex systems. Other examples include participatory activities where students could take the role of systems' agents (e.g., a virus carrier) and follow the local rules for their actions and observe both their role and the system behaviours (e.g., disease spread) in a computational simulation (Colella, 2000; Danish, 2014).

The second strand concerns the design of learning environments based on complexity-informed conceptions of knowledge and learning (Davis & Sumara, 2006). Such design is built on a view that understanding is not instantaneous and linear but emerges through the interaction of multiple arguments and viewpoints (Doll, 2015). Individual sense-making and collective understanding, in this view, are emergent and inter-dependent, thus designing learning environments need to consider agency, creativity and diversity at the individual level as well as collective interaction. The second row of the digital map showcases theories of learning connected to complexity discourses. The third and fourth rows of the map focus specifically on the two strands of complexity research in the learning sciences.

Discussion

The two strands of research we identified in our review, namely *complexity as a subject matter* and *complexity as a frame* to study knowledge and learning stem from different conceptual views towards complexity and the relationship between learners and disciplinary knowledge. The first strand mostly focuses on designing tools and environments to support students understanding about complex phenomena. Therefore, although the subject matter and the curricular aim for students to achieve a better understanding of complex systems (e.g., feedback mechanisms in systems) through individual or collective modeling activities, the computational and non-computational tools and curricula do not necessarily encourage the expression and interaction of learners' diverse perspectives and exploring complex phenomena in context. A more comprehensive complexity view of knowledge and learners would expect learners to create diverse meanings and views about the same phenomena.

The second strand looking at the dynamics of learning and knowledge production, uses complexity discourse mostly to elaborate how individual and collective learning are different but interconnected emergent systems. From this viewpoint, the produced knowledge is not a separate entity from learners. Knowledge is produced as learners interact with the world and expand their horizons of interpreting phenomena. There is, however, a lack of empirical work that examine the proposed design conditions within this strand. We, therefore, argue that each of the two strands has its own merits with limitations. We argue for a possible dialogue between these two strands that could inform a view of education that both enables learners' better understanding of complex issues and allows for diversity and inclusion of different viewpoints, skills and interests.

Interface as an Integrative Framework for Understanding Learning and Knowledge Acquisition in Public Library Contexts

Sari Widman, University of Colorado, Boulder, sari.widman@colorado.edu

Abstract: Public libraries are increasingly leveraging both physical and digital space for community learning. In this conceptual piece I build on Björneborn's libraries as "*integrative interfaces*" framework as an analytical tool for understanding the material and relational interactions that impact library patrons' uniquely complex learning experiences across space. I argue that this lens can illuminate structures of power and their impacts on interaction, access, and learning, across physical and digital space.

Introduction

Over the last decade, the Learning Sciences has increasingly recognized the significance of libraries as spaces for community learning and accessing resources, especially for under-resourced communities (Lee & Phillips, 2019; Ito & Martin, 2013). While the physical spaces of libraries are important parts of community social infrastructure (Klinenberg, 2018), digital learning experiences have become increasingly prevalent with the integration of STE(A)M education. As public libraries increasingly mix the digital and physical, it is important to understand embedded and connected learning across space, as well as how inequity translates. In this conceptual poster paper, I build on Björneborn's (2008) libraries as "*integrative interfaces*" framework, as a way to understand sociomaterial activity that impact patrons' learning experiences in libraries. By thinking about physical and digital space through this lens, we can illuminate architectures and structures of power across both types of space, as well as the implications of these structures on interaction, access, and learning.

Conceptualizing interface

The term interface is most often used to describe the visual and structural frames that a user interacts with in digital space. However, interface can also be observed and understood in physical space through architectural design, spatial layout, and the policies and norms that shape behavior and interactions. Media and technology theorist Alexander Galloway (2009) provides two examples of how interface has been considered and conceptualized: as a "surface" (like a screen) to be interacted with, or a portal. Citing French author François Dagognet, Galloway prompts us to consider that the interface, "both separates and mixes the two worlds that meet together there" (Galloway, 2009, p.32). Galloway also conceptualizes interface as being a "process or a translation", rather than a "thing" (2009, p.33).

Putting this conception of interface into conversation with sociocultural learning theory, interfaces can be considered as places of mediated activity. Mediating tools, including "social others and artifacts" (Yamagata-Lynch, 2010, p.2) can be encountered as an aspect of a digital or physical interface. From this perspective, interface could be seen as the activity that occurs at the meeting place between, "biological individual, the cultural mediational artifacts, and the culturally structured social and natural environments of which persons are a part" (Cole & Wertsch, 1997, p. 253). An interface may also be considered as a boundary, or a place where sociocultural differences between two activity systems, "give rise to discontinuities in interaction and action" (Akkerman & Bakker, 2011, p. 139).

Interface in the public library context

Applying the concept of interface to library contexts, Danish information studies scholar Björneborn (2010) developed a conceptual framework of libraries as "*integrative interfaces*" where users can interact with, "a multimodality of human, physical, and digital information resources" (2010, p.143). These three types of information resources support each other as parts of a whole, necessitating the consideration of design across all of the "contact surfaces" a library patron might interact with (Björneborn, 2010, p.144). Specifically, the framework was developed to examine design dimensions that facilitate exploratory (unplanned) information seeking behaviors in library patrons.

Interface as a conceptual framework to inform analysis

Using a socio-cultural lens and drawing on Galloway's conception of interface, I propose an expansion of Björneborn's framework for a power-focused analysis of diverse forms of learning and knowledge acquisition in libraries. Below, I detail how an expansion of this framework might be understood and operationalized.

Based on Galloway's conception, interface is understood as occurring in digital and physical space through encounters with elements of the space or social interactions in the space (what Björneborn (2010) would call “contact surfaces”). Physical “contact surfaces” of the library could include architectural elements, spatial arrangement, and mediating tools such as a book, or a soldering iron in a Makerspace. Digital “contact surfaces” might include the contents and architecture of a library’s Facebook page or website, a digital cataloguing system, or other digital tools. Interfaces tend to be nested, and can be encountered sequentially or simultaneously. Elements of digital space are always encountered *in* physical space, whether in the library, the home, or elsewhere. Social interactions are understood as crossing both physical and digital space.

Looking at the boundaries that occur at interfaces allows for analysis that illuminates issues of equity and access. Boundaries encountered at interfaces can be considered as material or sociocultural, and may be permeable or impermeable. Aspects of the design or social arrangement of learning spaces encountered at interface can allow or disallow participation.

One example of boundaries in action can be seen in the institution of airport-style security checks at Millennium public library in Winnipeg. A study conducted by Millennium for All, a group of concerned community members, found that the screening policy was discriminatory and blocked access to information and shelter for those who relied on those resources most (Selman et al., 2019). As they interfaced with security guards, the threshold of the library became an impermeable boundary for members of the public who’s racial, gender, or class identities made them vulnerable to a culture of surveillance due to experiences of excessive policing or trauma. The interfaces they encountered at the entrance of the public library was not a portal, but a barrier to accessing nested interfaces inside the library that could lead to learning and a sense of safety.

Affordances and possibilities

Conceptualizing interface affords analyzing how institutional power shapes learning experiences through social interactions and as a function of the arrangement of digital and physical space. While libraries are public spaces, they are not necessarily equitable or equally accessible. Public spaces are often contested sites between neoliberal interests and non-dominant communities (Córtez & Gutiérrez, 2019), and racial bias and structural oppression is equally present in the digital landscape (e.g. Noble, 2018).

While the frame of interface can illuminate barriers to participation, it can also surface characteristics of library interfaces that open participation, and facilitate community connection and collaborative learning. It can serve to highlight the agentic moves participants make through their encounters with interfaces, including subversions of the intended usage of a particular tool or design.

The interface frame also has the ability to work across Learning Sciences and Library and Information Sciences. There has been increased interest in bridging the disciplines, (Lee & Phillips, 2018) which may have different ways of understanding the activity in libraries. The framework also necessitates deep engagement with the library context. This is significant, as many LS studies of learning programs in libraries, have treated the library context as incidental to the program being implemented there.

Anything But Race: Race-Evasion and Color-Blindness in Preservice Teachers' Responses to a Hypothetical Scenario

José F. Gutiérrez, S. Shiver, Tracy Dobie, Rachel Francom, Lauren Barth-Cohen
jose.gutierrez@utah.edu, s.shiver@utah.edu, tracy.dobie@utah.edu, rachel.francom@utah.edu, Lauren.BarthCohen@utah.edu
University of Utah

Abstract: This paper contributes to the literature challenging color-blind racism in teacher education by presenting findings from a study involving elementary preservice teachers responding to a hypothetical teaching scenario about race. Framed by theoretical perspectives on race-evasive teacher identity studies and color-blind racism, our findings reveal four typical response components—*apologize*, *explain*, *solve*, and *appreciate*. We describe each component and explain how all four can serve to evade race and hide/reproduce color-blind racism.

Background and research purposes

What do elementary preservice teachers (PSTs) know about race and how it influences classroom teaching and learning? What assumptions or previous understandings do PSTs bring to bear to make sense of and address racial situations they might encounter in future teaching? How do we build on—and possibly confront—their prior knowledge? These are the thematic questions that guide our work as teacher educators and researchers as we consider our responsibilities in preparing teachers for diverse classrooms.

The work reported here is part of a larger project improving our home institution's elementary teacher licensure program. One of the broader aims is to incorporate social justice content and learning activities PSTs can engage across their program coursework. To pursue this aim, our signature methodology involves designing and empirically evaluating the use of *hypothetical teaching scenarios* to support teachers learning about diversity, inclusion, and justice in elementary education. This study analyzes a subset of data involving PSTs discussing a scenario in which a 5th-grade student reports a racial grievance (Figure 1). In small groups, the PSTs discussed how they would respond to the grievance and confront their potential racism and biases.

Responding to Student Grievance

Imagine you are teaching a 5th grade class. A student asks to talk with you privately and you agree to meet with them. They start the conversation as following:

Student: **"I don't know how to say this, but... it seems like you only call on the same three white students to show their work at the board. And I have my hand up too! But you never call on me... What's up with that?"**

How would you respond? Please write the next one or two lines of dialogue for what you might say or do.

Figure 1. "Responding to Student Grievance."

Critical whiteness studies, color-blindness, and race evasion in teacher Ed.

Critical Whiteness Studies in education is the broader paradigm in which this study is situated, wherein the theoretical and analytic foci are shifted away from the experiences and achievements of students of color to *Whiteness*. Whiteness is comprised of ideological as well as material forms of racial privilege and advantages for the dominant racial group (Gillborn, 2005; Leonardo, 2013), that is, for people who are born white. Additionally, scholars argue that Whiteness goes "undetected and proceeds as part of normalcy and racial common sense" (Leonardo, 2013, p. 93) in large part through the racial ideology of *color-blindness*.

How can teachers' perceptions be considered racist if there is no direct discourse about race? For this paper, we focus on one of Bonilla-Silva's conceptual tools for analyzing *color-blindness* and how it becomes re/produced in interaction. *Anything But Race* (ABR) is a rhetorical strategy that "allows whites to explain away racial fractures in their color-blind story" (Bonilla-Silva, 2018, p. 86). The overwhelming majority of participants in our study dismissed race as a relevant aspect of the scenario. "[W]hites explain the product of racialized life (segregated neighborhoods, schools, and friendship networks) as nonracial outcomes and rely on the available stylistic elements of color blindness to produce such accounts" (Bonilla-Silva, 2018, pg. 87). This study demonstrates how our PST participants, as a group, employed ABR as a means of making sense of the scenario.

The university and licensure program where we teach and do research is a predominately White-serving institution. There is incontrovertible evidence that, absent any racial awareness or a capacity to engage in race dialogue, White preservice and in-service teachers tend to evade, deny, or minimize the salience of race in classroom teaching and learning (Jupp et al., 2019). Previous research also highlights the challenges teacher educators face as they attempt to inform White teachers' racial understandings and promote race-visible teaching (Hambacher & Ginn, 2020). This study contributes to ongoing efforts in social justice-oriented teacher education and builds on previous research by providing clear and detailed descriptions of preservice teachers' racial sense-making during collaborative engagement with a hypothetical teaching scenario.

Summary of data, findings, and discussion

We analyzed PSTs' written responses and rhetorical moves during small group dialogue. Our main findings reveal a pattern of interpretation across all groups (14 groups; N=46) that reproduces color-blind racism. Furthermore, we have discerned four typical response components from our data—*apologize*, *explain*, *solve*, and *appreciate* (Gutiérrez et al., 2020). Here we argue that the different components serve the same functions, to evade race and reproduce color-blind racism; this paper discusses how each component does so in its own way and how the four combine and work together to explain the racial grievance as "anything but race" (Bonilla-Silva, 2018).

While typical explanations (e.g., "it was an accident"; "I try to choose a variety of students and he might be seeing it wrong"; or "I call on students who raise their hand first") expressly evade race, indirect apologies (e.g., "I'm sorry you feel that way") provide auxiliary support to the race-evasions and carry out the emotive work of color-blindness. Often, apologies came first, before an explanation. We speculate that apologies do the initial work of distancing PSTs from the scenario and begin to undermine the student's claim that a racial disparity has occurred. Some of the groups stated that teachers have to address the situation and (pseudo) apologize to control the situation and move past it. All 14 group conversations reflect an interaction in which PSTs pushed for a color-blind interpretation of the scenarios. Some groups did this implicitly by NOT mentioning race, smoothly and quickly shifting the conversation away from race, and proposing a typical four-component response. Here is a representative example: "This is hard for me to answer, because I know as a pre-service student NOT to only chose the same students to answer {*explain*}. In this situation, I would apologize to the student {*apologize*} and let them know that I appreciate their responses/help {*appreciate*} and promise to call on him more {*solve*}."

In summary, the evasions we observe in our data are performed as an attempt to absolve and excuse PSTs from doing the work of race (Rosenberg, 2004). These evasions also allow PSTs to furnish responses to the student's grievance—i.e., to "*solve* the complaint"—in ways that they perceive are good teaching practices, such as using a random generator to call names, eliciting input from the child, and so forth. However, we maintain that these race-evasive moves, reflected in all the groups, do not challenge racial discrimination or bias and therefore perpetuate it in the everyday practices of classroom teaching and learning. To remove race from the scenario, a PST needs to believe that racial bias is impossible, the teacher plays zero role in discrimination, and, as a consequence, the classroom opportunities they will provide in future teaching will be the same for "all students" so long as they "just do popsicle sticks" and "make sure everyone's participating." All this reinforces racial inequality in education.

Teachers as Learners in Research Practice Partnerships: A Design Narrative of a Social Design Experiment for Maker-based Learning

Emily Schindler, UC-Irvine, eschind1@uci.edu

Abstract: This paper offers a comparison of three distinct logics applied to both teacher learning and to modes of research practice partnerships. Further, this paper puts these modes of partnering in conversation with one another, to reveal that in fact, research practice partnerships and participatory design-based partnerships often rely on teacher learning, or change in practice, as an essential component, though this fact is only foregrounded in one mode of partnership: social design experimentation. Keywords: Teachers-as-learners, maker-based learning, social design experimentation, research-practice partnerships

Introduction

When it comes to teachers-as-learners (Russ, Sherin, & Sherin, 2015; Walkoe & Luna, 2019), there is much left to know, despite the fact that entire fields of educational scholarship (like Educational Leadership, Teacher Education, for instance) take the definition of teacher learning as settled knowledge. However, critical theorists point out that "teachers" and "learners" occupy constructed identities which enable schooling to perpetuate the social status quo (Apple, 1985; Bernstein, 1977; Bourdieu, 1984); indeed, the binary identity of teacher vs. learner is unnatural. Therefore, if learning scientists take seriously that learning happens outside of formal structures and recognition via social participation (e.g. Lave & Wenger, 1991; Rogoff, 2003), it stands to reason that teaching does as well. Still, scholars struggle to conceive of teachers-as-learners beyond explicit pedagogical training environments (Russ, Sherin & Sherin, 2015) Teacher learning is often a mechanism of change in RPPs. In this context, epistemological orientations which impact RPP design vary according to the following question: 1) Is the purpose of educator learning to afford systemic coherence, systemic disruption, or some combination of both? 2) What counts as relevant learning for educators? 3) Who counts as a teacher in discussions of teacher learning?

Theoretical analysis: Teachers-as-learners and RPP design methodology

In this brief analysis, I take up the high-level epistemological tensions that arise from differing beliefs about educators and learning produced by three different fields: educational leadership, teacher education, and learning in informal institutions. To be clear, while this analysis draws upon these fields for information, it is not exhaustive.

Tension #1: Educator Learning as Means to Coherence vs. Educator Learning as a Means to Disruption

Teachers-as-Learners: A high level look at the fields of educational leadership, teacher education, and informal learning reveals a discrepancy around the overall goal: is the purpose of educator learning to generate coherence around a central goal or is the goal of educator learning to produce disruption? For instance, in Educational Leadership, the goal of educator learning is ultimately systemic coherence, though educator learning is recognized as a mechanism for iteration upon systems of schooling.While critics might attack this approach as insufficiently responsive to local, or bottom-up, innovation, proponents argue that systematized dynamics of inequity require systematized corrections (Ladson-Billings and Tate, 1995). The field of Teacher Education responds to the notion of teachers as middle managers differently: since educators convene power through praxis, in addition to their role within the system of schooling, their learning process, identity, and goals ought to provide the foundation for systemic change improvement. Informal learning institutions are caught between systemic coherence and disruption, because on the one hand, they view themselves as part of a wider learning ecology, but on the other, the reality of informal learning institutions is that they are working toward curricular collaboration with formal institutions. When it comes to informal educator professional learning, museums and libraries see their job as supplementing learning taking place in formal schools (Allen & Crowley, 2017; Brahms & Crowley, 2016). *RPPs*: This tension is most obvious in the difference between participatory design partnerships (Bang & Vossoughi, 2016), including social design experiments (Gutierrez & Vossoughi, 2010), and more top-down, organizationally-dependent models of partnering, like design-based implementation research (DBIR) (Penuel & Fishman, 2012). Though both social design experimentation and DBIR rely upon teacher learning as a change mechanism, they diverge when it comes to systemic coherence vs. disruption.

Tension #2: Educator Learning as Discovery vs. Educator Learning as Transmission

Teachers-as-learners: Russ, Sherin, & Sherin (2015) take up the question of what constitutes educator learning by categorizing the types of knowledge or skill acquisition that have been proposed as constitutive of teacher learning. In other words, this scholarship seeks to understand what educational scholars are talking about when they mention teacher learning. Their review proposes three different conceptualizations teacher learning: process-product (where teacher knowledge is constituted by individual strategy development), cognitive modeling (where teacher knowledge follows a predictable trajectory that increases in complexity throughout a career), and a situative/sociocultural approach (where teacher knowledge is constituted by situated social interaction). While it is generally unwise to amplify one argument about teacher learning as the truth, the analytical work presented by Russ, Sherin, & Sherin provides a useful "object to think with". *RPPs:* The complexity of this belief cannot be overstated, nor can the effect of one's epistemological orientation regarding knowledge about educators-as-learners for the design of educator learning environments. In the design of RPPs for teacher learning, one's stance on this issue determines whether teachers co-design, or receive, learning.

Tension #3: Educator Identity

Teachers-as-learners: The last tension concerns how one identifies and designates individuals as educators, and further, how educators identify and designate themselves. Given the fact that teaching and learning activities occur outside of formal and informal learning environments as everyday processes of adaptation and participation (Rogoff, 2003; Rogoff and Gutierrez, 2003), it stands to reason that all humans learn and teach throughout the course of participation in social communities. Still, anyone who has ever had a bad teacher in school understands that being a professional Teacher in formal and informal spaces requires specialized skills that transcend content knowledge. This assertion, foundational to the reasons university-based Teacher Education programs exist, is often mobilized in fights related to labor relations for formal Teachers.

There are few opportunities for educators from informal and formal learning environments to share knowledge and expertise, perhaps due to the fact that all educator expertise is systematically devalued in the ways I've outlined. The result of this is a narrowing of "who counts" as an educator, and whose teaching is "real" or "legitimate". *RPPs*: The epistemological orientation one occupies with respect to "who counts" as an educator is crucial to the design of educator learning environments, because it indicates whose expertise and practice counts as a resource for learning.

Implications

This design narrative, combined with the theoretical framing which troubles well-worn assumptions about teacher learning, reveals the need for further research into activity-based inquiries into teacher learning. Whereas the impact of research-practice partnerships has been examined through various lenses, like social change, scalability, and sustainability, there is much to learn about the impact of design-based partnerships as learning environments themselves, for both designers and participants.

Learning with Purpose: Orienting Student Agency Towards Community Solidarity in a Secondary Science Curriculum

Samuel Severance, University of California, Santa Cruz, sseveran@ucsc.edu

Abstract: This study uses a framework, *learning with purpose*, to support the design and analysis of student learning opportunities in science. Researchers and practitioners developed and implemented a secondary biology unit for use across an urban district in the US wherein students engaged in a community-based citizen science design challenge. Results suggest student agency may influence how students experience and assign purpose in their learning.

Keywords: Purpose, Agency, Science Education, Reform, Curriculum

Introduction

Designing formal learning experiences that students see as relevant to their lives and the world outside the four walls of the classroom has proven an enduring challenge in science education (NRC, 2007). In the years since the advent of recent science education reforms (see NRC, 2012), researchers and developers have taken up this challenge with renewed vigor. Yet, even when using innovative instructional models (e.g., Project-Based Learning) and innovative curriculum designed to reflect reforms, meaningful science learning can remain elusive for all students (Pitts, 2008; Priester, 2020). The aim of ensuring students have learning they find meaningful in the science classroom holds particular significance for addressing inequities in science education; learning that fails to prove consequential to all students by ignoring the strengths students bring from outside the classroom serves to reproduce patterns of marginalization experienced by non-dominant students (Lee & Buxton, 2010).

Learning with purpose

Using a sociocultural perspective and ideas from cultural psychology, this study uses a framework, termed *learning with purpose*, to support the design of more meaningful schooling and its analysis. Much as how leveraging the cultural funds of knowledge students bring to the classroom can promote more meaningful and culturally-relevant learning, this framework proposes that the purposes students and their families orient towards can serve as particularly powerful cultural strengths for learning. At its core, a learning with purpose approach seeks to create opportunities for all learners to act in solidarity with and for their communities. Cross-cultural studies have shown how the act of taking initiative to "pitch in" and contribute to a group endeavor appears more prevalent in non-dominant families, such as indigenous and Latinx families (Rogoff, 2014), than in European American families. The prevalence of this practice indexes a shared purpose where individuals' activity arcs towards serving the needs of a collective or group (i.e., a community). Ladson-Billings (2000), when discussing orientations in the Black community in the US, noted how central this purpose can prove to peoples' existence, a notion well-captured in the African saying *ubuntu*: "I am because we are." To conceptualize how students can collectively engage in learning with purpose over time and at various levels (see Smith, 2020), this framework draws on Leontiev's (1978) notion of the structure of activity: learning with purpose requires students always move towards the *motive of their activity* (e.g., protect our ecosystem) through smaller *actions and goals* (e.g., find patterns with species) and yet smaller *operations* (e.g., writing notes). Lastly, learning with purpose requires students have meaningful agency in their learning. Students must have opportunities "to act (not merely to know)" (Eisenhart et al., 1996, p.282), to use their learning to do something they and their communities see as important.

Design and implementation of biology unit

To achieve an inclusive vision of science education where all students have opportunities to engage in learning with purpose—while also meeting the aims of science education reforms—proves no small design challenge, particularly at large scales (e.g., school districts). Through a co-design approach, researchers and practitioners from an urban school district in the US developed an 8-week secondary biology unit on ecosystems aligned to reforms in the US, namely the *Framework for K-12 Science Education* (*Framework*; NRC, 2012). Part of the district's official biology curriculum, researchers and teachers saw the unit as a means for all students across the district to engage in more purposeful learning. The vision of the *Framework* offers areas of convergence with a learning with purpose approach, including having students' learning orient towards a phenomenon and/or problem relevant to students' lives and communities, as well as positioning students with epistemic agency (Miller et al., 2018). The ecosystems unit employs these aspects in a way intended to blur school and community and position students with the agency to act. In response to a pressing threat (i.e., an invasive species about to eradicate trees throughout the city), the unit has students take up a citizen science design challenge. This challenge—where students can wield science *in* practice (Penuel, 2014), while acting in solidarity with and for their community—asks students to use science and engineering practices to decide what tree their class should plant and where to maintain the biodiversity and services of their ecosystem. Community members helping to enact students' solutions included the city's parks department and local non-profits. Twelve teachers from eight schools piloted the unit with approximately 975 students. Latinx students comprised around 56% of students, Black students comprised around 14% of students. One classroom, where 92% of students identified as Latinx and 5% identified as Black, served as a focus of study. Researchers used daily surveys across all schools to collect practical measures of students' experiences for each lesson. In the focus classroom, researchers conducted twelve observations as well as three interviews with two Latinx focus student (FS) participants. A mixed methods approach to analysis, including using rounds of inductive and deductive coding (Emerson et al., 2011), focused on ascertaining (1) whether students experienced learning with purpose and (2) how the unit mediated such experiences.

Results and discussion/conclusion

Students' survey responses across all classrooms indicate that, on average, they saw their learning in the unit as relevant to the community (64%) but less so to their class (39%) and themselves (29%); focal students also saw their learning generally as more aligned with the community's purposes. Interestingly, when students noted on surveys that a lesson connected strongly to the citizen science design challenge, these responses showed a moderate correlation to students reporting their learning as relevant to themselves ($r(1222) = 0.32$, $p<.001$) and to a slight degree their class ($r(1222) = 0.14$, $p<.05$) but not to the community; data from focal students followed this pattern (e.g., "I don't think they'd [community] want to stop and ask why we're planting a tree," FS). Interview data from focal students also indicated that students felt more agency when working on the citizen science design challenge—both in terms of *actions* (e.g., using science and engineering practices) and the *motive for their activity* (e.g., planting a tree to help ecosystem: "…we provided this research, it should be like brought into like action, like how we're doing planting the tree," FS). These patterns suggest that the agency students experienced may have influenced how they saw and assigned purpose in their learning. With more agency, students associated purpose in their learning with more proximal communities (personal and class) than a more distant "community." This work demonstrates the challenges and promise of designing formal curriculum to promote learning with purpose. Future curriculum designs should continue to explore the interplay of purpose, agency, and community.

Acknowledgments

Collaborative development of the *learning with purpose* framework occurred within the New Gen Learning group at the University of California, Santa Cruz, an initiative made possible with support from the Spencer Foundation.

Using Augmented Reality for Biology Learning in High School: A Quasi-Experiment Study

Christy Weng-Lam Cheong, Macao Polytechnic Institute, wlcheong@ipm.edu.mo
Xingmin Guan, University of Hong Kong, xguan2@connect.hku.hk
Xiao Hu, University of Hong Kong, xiaoxhu@hku.hk

Abstract: A quasi-experiment was conducted to explore high school students' perception of Augmented Reality (AR) in biology learning and examine the impact of AR utilization on their academic emotion. The findings indicate students' general willingness to use AR applications and confirmed the capacity of AR in stimulating positive emotions towards the subject. This suggested that AR can be leveraged to sustain students' positive academic emotion and engagement in science education.

Introduction

Augmented Reality (AR) refers to a combination of technologies which overlays computer-generated content into the real world (Azuma, 1997). AR-facilitated learning was generally found beneficial for enhancing learning experience across the affective, behavioral and cognitive domains (Akçayir & Akçayir, 2017). In the affective domain, the impact of AR on academic emotions, i.e. emotions associated to learning, is yet to be measured comprehensively. Therefore, a preliminary quasi-experiment study was conducted to explore high school students' perception of AR in biology learning and examine the extent to which AR utilization affects their academic emotion. The findings contribute to the literature by providing empirical evidence on the impact of AR on academic emotions and will also be helpful for informing enhancement of AR applications in learning.

Research methods

The quasi-experiment was conducted in a high school in Southern China. Two Grade-11 classes having no prior experience with AR learning materials participated respectively as the experimental group and the control group. When this study was conducted, they had finished the standard high school curriculum for biology and were preparing for the National University Entrance Examination to be held at the end of Grade 12. The two groups had a lesson that reviewed cell structures. Students of the experimental group were invited to use a 3D vision-based AR learning material in the lesson where they were given a demonstration and a 30-minute usage in groups of four with technical assistance available. They could continue using it at home during the week after.

To understand students' perception of AR, a questionnaire survey was conducted in the experimental group one week after the lesson. The students were asked to report frequency of their after-class usage of the AR material and rate on a 5-point Likert scale their level of satisfaction towards it and experience of sensory immersion. The questionnaire items were adapted from those proposed and verified in Han, Jo, Hyun, and So's study (2015). To measure the impact of AR on academic emotion systematically, two questionnaires adapted from the Achievement Emotions Questionnaire (AEQ) (Pekrun, Goetz, Titz, & Perry, 2002) were administered one week before and after the lesson. The AEQ measures nine discrete emotions (i.e. enjoyment, hope, pride, anger, anxiety, shame, relief, hopelessness and boredom) in three types of academic achievement situations: class-related (triggered while attending lessons), study-related (towards the course or subject), and test-related (towards tests and exams). Focusing on the teaching and learning process, this study examined class- and study-related emotions.

Post-lesson focus-group interviews were conducted. Five sub-groups were selected on a random basis respectively from the two groups. In each interview, students were asked to discuss their perception of the lesson and the subject of biology. Students of the experimental group also discussed their perception of AR learning.

Findings

103 students participated in this study. Valid sets of questionnaires were collected from 88 students, among which 47 students were in the experimental group (26 males and 21 females) and 41 were in the control group (22 males and 19 females). 70.3% of the surveyed students (33 out of 47) in the experimental group reported that they had used the AR material at home. Among them, 11 (23.4%) used it more than once. A median of 3.00 or above was obtained across items, indicating that students were satisfied with the AR learning experience.

To measure the impact of AR on academic emotions, sufficient internal consistency for each emotion construct was confirmed using Cronbach's alpha ($\alpha \geq .690$) (George & Mallery, 2003). A Mann-Whitney U test per emotion was conducted on responses to the pre-questionnaire. The results indicate no significant emotional differences between the groups before the lesson except for study-related hope (p = .001). Therefore, a Mann-

Whitney U test was conducted within each group to compare the ratings on study-related hope before and after the lesson. For other constructs, a post-questionnaire Mann-Whitney U test was conducted per construct to compare the two groups' ratings. The results indicated that students in the experimental group tended to be more positive towards the lesson than their peers in the control group. After the lesson, their ratings of enjoyment (p = .000), pride (p = .006), and hope (p = .000)) were significantly higher than those of students in the control group while those of anger (p = .006) were significantly lower. Their ratings of boredom (p =.055) and hopelessness (p = .075) were also lower than those from students in the control group though at the p = .10 level. As for study (i.e., subject)-related emotions, the findings indicate that AR did not make a significant impact on students' emotion towards the subject (biology) except for enjoyment (p = .05).

Findings from the focus group interviews align with the statistical findings. The perceived novelty of the AR material was found to be a stimulus of positive academic emotions and motivated the usage. Students also tended to find the opportunities of exploration in 3D space helpful for their understanding of the content concerned, making them enjoy the lesson and feeling interested and engaged. It was, however, noted that the technical requirement (both hardware and soft skills) for using AR might have possibly discouraged usage.

Implications and future work

This study confirmed the affordances of AR in helping students understand things that may not be easily seen or not at all present in the real world (Hughes, Fuchs, & Nannipieri, 2011). It found that the use of AR in learning tended to increase positive academic emotions and reduce negative ones, which was partially due to the perceived novelty of the technology (cf. Huang, Chen, & Chou, 2016). It also found that the impact of AR on class-related emotion was more obvious than on study-related emotions. This is possibly because the intervention was implemented as a single instance while belief and attitude tend to change in a slow process (Haberman, 1991). All in all, these findings suggested that user-friendly AR materials can help develop learning interest and sustain learning engagement in science education.

Distinguished by its systematic approach to academic emotion, this preliminary study is a starting point of further research on AR-facilitated learning and its affective effects. First, the intervention of this study was one AR material and one lesson followed by a week of after-class usage. The research design in subsequent studies will be extended with more AR materials and/or longer learner-material contact time to validate the findings. This will also provide an optimized setting to study the relationships between AR utilization, academic emotions, and learning performance. Second, the context of this study was a mixture of formal learning and self-study. User experiments could be conducted to test AR utilization in different learning settings. Third, this study used self-report to collect emotion data, which may lead to concerns of subjective bias. Sensor technology will be considered for psychophysical data collection in subsequent studies to reinforce the reliability of the findings.

Fostering Students' Argumentation Skills with Game-Based Learning Method: A Systematic Review

Omid Noroozi, Wageningen University and Research (The Netherlands), omid.noroozi@wur.nl
Hojjat Dehghanzadeh, Tarbiat Modares University (Iran), hojjat.dehganzadeh@gmail.com

Abstract: This study maps instructional support and learning outcomes of game based learning on argumentation skills. This systematic review report positive effects of game based learning on learning outcomes and instructional supports on argumentation skills. However, the reviewed publications did not report specific instructional support and game elements associated to the learning outcomes. This study provide suggestions on how to design digital games for argumentation skills and learners' learning outcomes.

Keywords: game based learning, argumentation, learning outcomes, instructional support

Introduction

Learners need to learn how to generate valid arguments, reason soundly, and engage in argumentation especially in academic settings (Noroozi et al., 2012, 2016, 2018, 2020). Learning to engage in argumentation is challenging for students due to the complex, non-linear, and ill-defined nature of argumentation. This is striking since the ability to construct valid arguments and exchange them with others in reasoned debate is one of the critically important real-world skills required in the workplace and community life (Latifi et al., 2020; Noroozi, 2018). Liu, Liu, & Lin (2019) reported that most of the high school students had difficulties to engage in argumentation either in collaborative, or individual environment. Students may have difficulties in exploring relevant literatures, incorporating the data to make a generalisable claim, using evidence to back their claims, and rebut an argument in light of evidences. To cope with these challenges, educational technologists have focused on scaffolding students' argumentation. Designing Game-Based Learning (GBL) environments for fostering students' argumentation skills has recently become popular, especially with respect to scientific results for real-world applications. GBL promotes scientific argumentation (Bressler, Bodzin, & Tutwiler, 2019).

Given vast scientific support for the positive impacts of games on various aspects of the learning processes, many researchers from different disciplines are committed to developing GBL to promote students' argumentation skills. Despite various review studies in the field of GBL and their effects on various aspects of learning processes and outcomes in different disciplines such as business, marketing, math, statistics, environmental sciences, biology, and psychology (e.g., Boyle et al., 2014; Dehghanzadeh et al., 2019; Qian & Clark, 2016), no review study has yet been reported for the impacts of the GBL on promotion of students' argumentation skills. Therefore, the main aim of this review is to clarify what empirical evidence exists with regard to the effects of GBL on students' argumentation skills. Therefore, this review follows these questions:

1. Which instructional supports that influence argumentation have been investigated?
2. Which game elements that influence argumentation have been investigated?
3. Which learning outcomes that influence argumentation have been investigated?

Method

A keyword search strategy was used based on the most important concepts of the study, namely GBL, argumentation. First, we identified synonyms and related terms using Merriam-Webster's Online Thesaurus in combination with the reviews of Ke (2016) as well as Qian and Clark (2016). Then, we combined the related terms with the Boolean operators OR and the three concept areas with AND to arrive at the following search string: game* OR gamification OR GBL OR game-based learning OR serious game OR learning games OR educational game OR entertainment game OR video games OR mobile game OR digital game OR edutainment game AND argument. To identify relevant publications, a systematic search strategy was executed in the bibliographic databases such as Scopus, ERIC, and Web of Science. Various inclusion criteria were used to include the most relevant publications which resulted in 18 publications selected for this systematic review.

Results

The most commonly used instructional support for argumentation were modeling (8), interactivity (4), feedback (2), and reflection (2). The most commonly used elements for gamifying argumentation were feedback (18), challenge (9), collaboration (9). The most commonly used learning outcomes for argumentation were improving high level of argumentation skills (6), engagement (5), collaborative learning (3).

Conclusion, limitation and future research

This systematic review presents an overview of the current state of the art on the use of game based learning for argumentation in learning environments. This review intends to contribute to a growing body of knowledge on designing game based environments for argumentation skills learning. It provides interested scholars with information on how to take advantage of potential benefits of game based learning for argumentation and how to design digital environments to improve students' learning processes and their corresponding learning experiences and outcomes. These findings (Table 1) are useful to commercial game developers, because the engagement potential of a game is important for game development, with the goal of establishing a compulsion to play.

We did not report common affordances and hindrances that are inherent to game based learning for argumentation skills. Gamified environments typically provide learners with various affordances that can be used with the help of ICT tools. More research is needed to shed light on the possible affordances and hindrances that are inherent to the use of game based learning for argumentation.

A Learning Sciences and Organizational Behavior Framework for Analyzing how College Instructors Learn Inclusive Pedagogies

Andrew Estrada Phuong, UC Berkeley, andrew.e.phuong@gmail.com
Judy Nguyen, Stanford University, judynguyen@stanford.edu
Christopher T. Hunn, UC Berkeley, cthunn@berkeley.edu
Fabrizio D. Mejia, UC Berkeley, fmejia@berkeley.edu

Abstract: This study identifies mechanisms that motivate college STEM instructors to learn and adopt inclusive teaching practices. Adaptive Equity-Oriented Pedagogy (AEP) has been shown to improve student learning by over a letter grade (Phuong et al., 2017a). We use van de Sande & Greeno's (2012) perspectival frames (e.g., positional, epistemological, conceptual) to understand how instructors reflect on their values and the values of their university, discipline, and industry. We introduce an emotional frame to examine emotional schemas that promote and inhibit instructors' behavioral changes and learning. We present a conceptual framework that uses these frames to explain what motivates instructors to integrate knowledge about AEP (e.g., eliciting, adding, distinguishing, revising their ideas about pedagogy) (Linn & Elyon, 2011).

Research questions and significance

Research shows that 90% of college students leaving STEM cite poor teaching (e.g., a lack of alignment between instruction and assessment) as a primary concern (Seymour & Hewitt, 1997). High STEM attrition rates persist especially for underrepresented minority (URM) students (Sax et al., 2018). Studies show that STEM instructors applying adaptive equity-oriented pedagogy (AEP) have improved student achievement by over a letter grade (Phuong & Nguyen, 2019). AEP is defined as adapting instructional practices (e.g., productive struggle, modeling key skills, deliberate practice, providing feedback) based on student learning data (e.g., formative assessment, observations, surveys) (Phuong et al., 2017a). The AEP practice elements include 1) Clarify learning outcomes; 2) Align formative assessments with outcomes; 3) Diagnose students' competencies, interests, and equity barriers to meeting outcomes; 4) Adapt teaching based on diagnoses; 5) Iterate: Demonstrate a continuous commitment to adaptation and improvement (Phuong et al., 2017b). For this study, we explore the research question: What are the cognitive, emotional, and socio-organizational mechanisms that facilitate instructors' learning of AEP?

Conceptual framework and methods

To account for socio-organizational factors impacting instructor learning, we use van de Sande & Greeno's (2012) perspectival frames (e.g., positional, epistemological, conceptual) to understand how instructors look outward and inward to reflect on their values and the values of their university, scholarly field, and industry. We introduce an emotional frame to examine emotional schemas that impact instructors' behavioral changes and learning. We offer a conceptual framework that uses these frames to explain what motivates instructors to progress through the knowledge integration cycle of learning AEP (eliciting, adding, distinguishing, revising) (Linn & Elyon, 2011).

The **positional** (e.g., power and community) frame is defined as the content valued by the authoritative figures in the field-- do peers, the scholarly field, the industry, and those I'm serving value the AEP practice? Is there a community of practice around equity-oriented teaching? The **conceptual** (e.g., relevance) frame is defined as the concepts or ideas that one foregrounds in their mind-- is the AEP practice relevant to my teaching and goals that I am foregrounding in my mind? Are these AEP practices relevant to the course content and concepts that my organization and I prioritize? The **epistemological** (i.e., data frame) frame is defined as the kinds of knowledge and data that are important and relevant in an academic and socio-organizational culture-- do I value certain kinds of practices because they are tested using data sources and methods that are important to me or my field? The **emotional** frame is defined as the emotions that arise from engaging in a practice, experience, or reflection-- does the data from implementing these practices help me feel more valued, fulfilled, and connected to my organization and those I'm serving? Is the experience energizing me or burning me out?

We analyze written reflections from a faculty member and a student-instructor case study using the 4 frames to explain changes or lack thereof in AEP competency. We inductively and deductively coded data.

Findings

Here we present two sample analyses of a faculty member and a student-instructor. The faculty member is a white queer male and was a first-generation low-income college student. He has taught at the Computer Science department for 14 semesters or 7 years. The student-instructor, a white male, reported having about 1 year of classroom teaching experience, about 3 years of tutoring experience, and was enrolled in a pedagogy and data analysis course for first-time TAs. These case studies are important because a growing number of faculty, graduate, and undergraduate student instructors are becoming interested in inclusive teaching.

When writing about the values of the department, our analysis suggested that the faculty member relies on emotional framing. Although epistemological framing was present, emotional framing was dominant for this instructor. For instructors like the faculty in this case study who care about equity, finding data that students do not meet learning outcomes is devastating and motivational towards creating better pedagogy. These emotions motivate how the faculty member applies the AEP practice element of diagnosing student learning needs:

Faculty written reflection	*Frame*
I feel **horrible and sad** when **students are not meeting my learning outcomes** when I collect formative assessment and student feedback […] When I **collect data with AEP, I know why students are not learning based on data**. So when I feel **sad or disappointed,** the data from AEP gives me an idea of what the next step should be to adjust appropriately and improve student learning. **I don't feel hopeless and know I have a methodical AEP framework that has helped me make a difference** […] **AEP can help me impact students' emotions especially when I get feedback from students.** I use **formative assessments and student feedback loops** and this will inherently help me understand students' emotions. It's a process that can help me **build stronger relationships so that I can dynamically drive better outcomes**. Because I believe in having a growth mindset, I am always experimenting with new teaching practices, reflecting, and revising my teaching approaches […] I **love teaching more when my students love learning**. I am the happiest when this happens! [bolded for emphasis]	Emotional Epistemological Emotional Conceptual Emotional Epistemological Emotional Emotional

The student-instructor uses a positional frame to explain how authoritative figures and peers reinforce an epistemological value for data that is rooted in the Computer Science department's disciplinary culture. He acknowledges the limitations to data. And, he invokes an epistemological frame related to his discipline to highlight how he came to prioritize data-driven decision making through key concepts and skills in his discipline (e.g., "machine learning"). His thought process is echoed by the Silicon Valley community:

Student-Instructor written reflection	*Frame*
All professors I have had at Berkeley seem to be constantly **asking for feedback and information--data. TAs are always sending feedback forms, GSIs are sending out intro-surveys, mid-semester surveys,** and internal and **University surveys at the end of the semester** […] In general, Berkeley seems to be one of the **major universities in the machine learning field,** which is naturally data-heavy. This, as well as the **data frenzy within nearby Silicon Valley,** creates a **culture within the university of relying on data.** […] However, **data is not all objective**, and can have some major problems[bolded for emphasis]	Positional Epistemological Positional Epistemological Epistemological

Implications and conclusions

These case studies show that the four frames can help researchers and instructor professional developers understand cognitive, affective, and socio-organizational factors that drive instructors' motivations for learning inclusive practices. This framework is important for helping instructors reflect on their values and for instructor professional developers who want to motivate college instructors to promote inclusive teaching and student success, which are important for diversifying faces of success in academia and our workforce.

Abstract: This study introduces a conceptual framework called the zone of proximal self which conceptualizes how interactions within a higher education learning ecology support students' progress towards their possible selves and the development of both academic and social-emotional competencies. Employing a case study approach with semi-structured interviews and surveys, the study presents findings on how the zone of proximal self impacts the experiences of undergraduate computer science mentors and students at a U.S. public, research-one university on the West Coast. Findings show how feared selves highlight inequities and reveal the importance of community. Additionally, mentors' socialization impacted their mentorship practices. This framework has significance for understanding the learning mechanisms and processes of mentors, which can inform equity-oriented programs that support all students.

Conceptual framework and literature review

In higher education university settings, students' future goals become salient, and students develop their academic and social-emotional competencies in pursuit of these goals. This study introduces a zone of proximal self (ZPS) framework to contextualize how students work with others to pursue their vision for their future. The ZPS framework draws upon Lev Vygotsky's (1978) sociocultural theory of human learning which emphasizes how learning is a social process. Vygotsky (1978) described how children's learning exists within a zone of proximal development, or "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem-solving under adult guidance, or in collaboration with more capable peers" (Vygotsky, 1978, p.86). Since higher education is a time where students are thinking about future opportunities, ZPS synthesizes the zone of proximal development with possible selves, i.e., the selves that we could become, and also the selves that we are afraid of becoming (Markus & Nurius, 1986). ZPS also acknowledges how academic and social-emotional competencies are developed in a learning ecology, defined as "the set of contexts found in physical or virtual spaces that provide opportunities for learning," which in higher education can include classrooms, programs, residential/dorm spaces, and peer groups (Barron, 2006).

Research questions

To study the conceptualization of ZPS, this paper examines the following research questions within a computer science mentorship context: 1) How do computer science undergraduate student mentors and mentees frame their possible selves? and 2) How do mentors' socialization of the computer sciences field impact their own future pathways and the way they mentor different mentees?

Methods

This study employs a qualitative case study approach (Yin, 2007) to unpack examples from a real-world computer science context. Undergraduate student mentors were recruited from a computer science graduate-level teaching course. 5 undergraduate student mentors participated in the study. 14 undergraduate computer science students were recruited from a student success program. The program selects students with little to no exposure to computer science that identify as a member of one or more of the following groups: first-generation, low-income, historically underrepresented in the field (i.e., Black/African American, Chicanx/Latinx, and Native American), and/or female. Two mentors were Chinese American, one Korean American, one Japanese American, and one

Chinese Australian. Three of the mentors identified as female, while two identified as male. Of the fourteen students in the program, 71.4% were female and 64.3% were first-generation. Their race/ethnic background was 42.9% Latinx/Chicanx, 14.3% Southeast-asian, 14.3% South Asian, 14.3% East Asian, 7.1% Middle Eastern, and 7.1% White.

Five undergraduate mentors were paired with two mentees: one in the student success program and one not in the program. The mentors were not given instructions on how to mentor their respective mentees. The mentors met with their mentees for at least eight times each in a 14-week-long semester. At the semester's end, the mentors participated in a semi-structured interview virtually on Zoom about their mentorship beliefs, practices, and experiences. Students from the student success program took an online survey via Qualtrics which had a total of 26 questions with Likert-scaled and open-ended response options about their current academic and social-emotional competencies, possible selves, social networks, and future goals. The mentor interviews were audio-recorded and transcribed. To analyze the interview transcripts and survey responses, deductive and inductive thematic coding was done using a codebook with common definitions to guide a ZPS analysis (Saldana, 2015).

Findings

When describing their possible selves, students described their ideal selves in terms of their dream occupation and desire for financial stability. A topic emerged, however, within feared selves that did not come up for ideal selves: the role of social environments and communities. Students described social-related concerns including gentrification, leading a team, and familial obligations. A student in the success program wrote in the survey, "I don't want to be a gentrifier, ESPECIALLY in my community/communities like mine." Another student in the program expressed the following: "[I have concerns with] confidence in myself and nervousness during interviews/while leading a team." Similarly, in the mentor interviews, Esther and Colette (pseudonyms) expressed concerns with the support they would receive from the social environment in their future workplace. Esther described how she wanted a working environment with "no one picking on your ideas and asking questions without being ridiculed." Esther's word choice focuses on what she does not want, which sheds light on a feared possible self in relation to interactions with others. Colette also hints at similar thoughts in her interview when she says, "I don't think I'm looking for a place that's cut-throat, a lot of companies with reputations for being not so great for being working there..." The findings show how feared selves reveal stories of what students fear not only for themselves, but for their immediate family, community, and workplace culture. Feared selves reveal issues of equity within higher education STEM structures and institutions. Students' feared selves are connected to the messages they receive about computer science being cutthroat, unsupportive, and technically focused.

Based on their socialization, the undergraduate student mentors' mentorship practices varied on a spectrum of non-adaptive to adaptive academic and social-emotional practices. Academic mentorship practices focused on the development of academic competencies, such as problem solving and technical skills. Social-emotional mentorship practices are defined as those where mentors focus on the development of mentees' social-emotional competencies such as building social networks and confidence in one's strengths. The degree to which mentors adapt does not seem to be related to the quantity of interactions they have within their learning ecology; rather, it is impacted by the quality of the interactions they had with perceived legitimate figures in their field. Therefore, mentors have been culturally shaped within a zone of proximal self and actively shape the zone of proximal self for other students. This research has significant implications, including the contribution of a conceptual framework that college administrators, mentors, and faculty can use to understand FLI and URM students' experiences and development in novel ways that guide equity-oriented programs.
