

# Lecture 13:

## Barrier Penetration and Tunneling

# Today

## Tunneling of quantum particles

- Scanning Tunneling Microscope (STM)
- Nuclear Decay
- Solar Fusion

## Next time: Time-*dependent* quantum mechanics

- Oscillations
- Measurements in QM
- Time-Energy Uncertainty Principle

## The rest of the course:

Next week: 3 dimensions - orbital and spin angular momentum  
H atom, exclusion principle, periodic table

Last week: Molecules and solids.  
Metals, insulators, semiconductors, superconductors, lasers, .

# "Leaky" Particles

Due to "barrier penetration", the electron density of a metal actually extends outside the surface of the metal!

$$x = 0$$

Assume that the work function (i.e., the energy difference between the most energetic conduction electrons and the potential barrier at the surface) of a certain metal is  $\Phi = 5 \text{ eV}$ . Estimate the distance  $x$  outside the surface of the metal at which the electron probability density drops to  $1/1000$  of that just inside the metal.

# Tunneling

In quantum mechanics a particle can penetrate into a barrier where it would be classically forbidden.

The finite square well:

In region III,  $E < U_0$ , and  $\psi(x)$  has the exponential form  $D_1 e^{-Kx}$ . We did not solve the equations – too hard! You will do this using the computer in Lab #3.

The probability of finding the particle in the barrier region decreases as  $e^{-2Kx}$ .

The finite-width barrier:

Today we consider a related problem – a particle approaching a finite-width barrier and “tunneling” through to the other side.

The result is very similar, and again the problem is too hard to solve exactly here:

The probability of the particle tunneling through a finite width barrier is approximately proportional to  $e^{-2KL}$  where  $L$  is the width of the barrier.

# Tunneling Through a Barrier (1)

What is the probability that an incident particle tunnels through the barrier?

It's called the "Transmission Coefficient,  $T$ ".

Consider a barrier (II) of height  $U_0$ .

$U = 0$  everywhere else.

Getting an exact result requires applying the boundary conditions at  $x = 0$  and  $x = L$ , then solving **six transcendental equations** for six unknowns:

$$\psi_I(x) = A_1 \sin kx + A_2 \cos kx$$

$$\psi_{II}(x) = B_1 e^{Kx} + B_2 e^{-Kx}$$

$$\psi_{III}(x) = C_1 \sin kx + C_2 \cos kx$$

$A_1$ ,  $A_2$ ,  $B_1$ ,  $B_2$ ,  $C_1$ , and  $C_2$  are unknown.  $K$  and  $k$  are known functions of  $E$ .

This is more complicated than the infinitely wide barrier, because we can't require that  $B_1 = 0$ . (Why not?)

# Tunneling Through a Barrier (2)

In many situations, the barrier width  $L$  is much larger than the 'decay length'  $1/K$  of the penetrating wave ( $KL \gg 1$ ). In this case  $B_1 \approx 0$  (why?), and the result resembles the infinite barrier. The tunneling coefficient simplifies:

$$T \approx G e^{-2KL} \text{ where } G = 16 \frac{E}{U_0} \left( 1 - \frac{E}{U_0} \right)$$

$$K = \sqrt{\frac{2m}{\hbar^2} (U_0 - E)}$$

This is nearly the same result as in the “leaky particle” example! Except for  $G$ :

We will often ignore  $G$ .  
(We’ll tell you when to do this.)

The important result is  $e^{-2KL}$ .

# Act 1

Consider a particle tunneling through a barrier.

1. Which of the following will increase the likelihood of tunneling?

- a. decrease the height of the barrier
- b. decrease the width of the barrier
- c. decrease the mass of the particle

2. What is the energy of the emerging particles?

- a. < initial energy
- b. = initial energy
- c. > initial energy

## Superconductor-Insulator-Superconductor Josephson tunnel junction (Eckstein Lab, UIUC SC quantum bit project)

# Example: Electrons in Nanoscale devices

*Nature* 434, 361 - 364 (17 March 2005)

Current measurement by real-time counting of single electrons

JONAS BYLANDER, TIM DUTY & PER DELSING

Electrons that successfully tunnel through the 50 junctions are detected using a fast single-electron transistor (SET).

# Application: Tunneling Microscopy

One can use barrier penetration to measure the electron density on a surface.

Barrier penetration is a wave phenomenon, not only QM.  
It is used in optical microscopes also. See:

[http://en.wikipedia.org/wiki/Total\\_internal\\_reflection\\_fluorescence\\_microscope](http://en.wikipedia.org/wiki/Total_internal_reflection_fluorescence_microscope)

# The STM

The STM (scanning tunneling microscope) tip is  $L = 0.18 \text{ nm}$  from a metal surface.

An electron with energy of  $E = 6 \text{ eV}$  in the metal approaches the surface. Assume the metal/tip gap is a potential barrier with a height of  $U_0 = 12 \text{ eV}$ . What is the probability that the electron will tunnel through the barrier?

# Tunneling and Radioactivity

In large atoms (e.g., Uranium), the nucleus can be unstable to the emission of an alpha particle (a He nucleus). This form of radioactivity is a tunneling process, involving transmission of the alpha particle from a low-energy valley through a barrier to a lower energy outside.

Why do we observe exponential decay?

- $\psi$  leaks out from C through B to A – the particle “tunnels” out.
- The leakage is slow ( $T \ll 1$ ), so  $\psi$  just outside the barrier stays negligible.
- The shape of  $\psi$  remaining in B-C shows almost no change: Its amplitude slowly decreases. That is,  $P_{\text{inside}}$  is no longer 1.
- The rate at which probability flows out is proportional to  $P_{\text{inside}}$  (by linearity)  $\Rightarrow$  exponential decay in time.

$$\frac{dx}{dt} = -Ax \quad \Rightarrow \quad x = e^{-At} = e^{-t/\tau}$$

$t_{1/2} = (\tau \ln 2)$  is the “half life” of the substance

# $\alpha$ -Radiation: Illustrations of the enormous range of decay rates in different nuclei

Consider a very simple model of  $\alpha$ -radiation:

Assume the alpha particle ( $m = 6.64 \times 10^{-27}$  kg) is trapped in a nucleus which presents a square barrier of width  $L$  and height  $U_0$ . To find the decay rate we consider:

(1) the “attempt rate” at which the alpha particle of energy  $E$  inside the nucleus hits the barrier (how fast is it moving?) Use Heisenberg...

**Rough estimate with  $E \sim 5$  to  $10$  MeV:** the alpha particle makes about  $10^{21}$  “attempts” per second ( $\sim$ velocity/nuclear diameter)

Width = 1 Fermi  
=  $10^{-15}$  meter

(2) the tunneling probability for an alpha particle with energy  $E$  each time the particle hits the barrier. [For this order of magnitude calculation we neglect  $G$ .]  
Here we use

$$T \approx e^{-2KL} \quad K = \sqrt{\frac{2m}{\hbar^2}(U_0 - E)}$$

Because of the exponential this factor can vary enormously!

## Act 2

Polonium has an effective barrier width of  $\sim 10$  fermi, leading to a tunneling probability of  $\sim 10^{-15}$ . Now consider Uranium, which has a similar barrier height, but an effective width of about  $\sim 20$  fermi.

Estimate the tunneling probability in Uranium:

- a.  $10^{-30}$
- b.  $10^{-14}$
- c.  $10^{-7}$

# FYI: Why aren't all atoms radioactive?

Why do only some atoms undergo radioactive decay?

It depends on whether they would have less energy in the decayed state than they do in the undecayed state.

Consider the following two possible potentials:

Here the  $\alpha$ -particle can tunnel to an allowed region, and gain KE (used for power, cancer treatment, bombs, etc.)

Here the  $\alpha$ -particle has NO allowed region to tunnel to, so the nucleus is stable against radioactive  $\alpha$ -decay.

# Tunneling Example: The Sun

The solar nuclear fusion process starts when two protons fuse together. In order for this reaction to proceed, the protons must “touch” (approach to within  $10^{-15}$  m of each other).

The potential energy,  $U(r)$ , looks something like this:

The temperature of the sun's core is  $T \sim 1.3 \times 10^7$  K.

This corresponds to an average kinetic energy:

$$k_B T = 2 \times 10^{-16} \text{ J} \quad (k_B = \text{Boltzman's constant})$$

At  $r = 10^{-15}$  m the height of the Coulomb barrier is:

$$\begin{aligned} U(r) &= (1/4\pi\epsilon_0)e^2/r = (9 \times 10^9) \times (1.6 \times 10^{-19} \text{ C})^2 / 10^{-15} \text{ m} \\ &= 2 \times 10^{-13} \text{ J} \end{aligned}$$

Thus, the protons in the sun very rarely have enough thermal energy to go over the Coulomb barrier.

How do they fuse then? **By tunneling through the barrier!**
